2. The *friction* is leſs in a body that rolls than it would be were the ſame body to ſlide, as is eaſily demonſtrated. For ſuppoſe a dented ruler, A B, *Tab. Mechanics, fig.* 12. and ſuppoſe a wheel DE to move along with it, with its teeth perpendicular to the circumference; if now the body were to ſlide, the tooth F, when it touched the ruler, would deſcribe a right line on the ſurface thereof, and, as the tooth of the ruler H reſiſts the ſame, it could not proceed without removing or breaking either the tooth H, or that F. And the ſame will hold in the ſliding of any rough ſurface upon another, where all the *friction* will take place that can any way ariſe from the roughneſs of the ſurface. But if the wheel ED roll along the ruler, then the tooth H will no longer reſiſt its motion, only as it is to be hoiſted out of the cavity F over the eminence of the tooth H; and the ſame holds in the rubbing of any rough body over the ſurface of another.

Hence, in machines, leſt the *friction* ſhould employ a great part of the power, care is to be taken, that no part of the machine ſlide along another, if it can be avoided; but rather that they roll, or turn upon each other. With this view it may be proper to lay the axes of cylinders, not, as it is uſually done, in a groove, or concave matrix, but between little wheels, ABCD, *fig.* 13. moveable on their reſpective axes: for, by this contrivance, the *friction* is tranſferred from the circumference of thoſe wheels to their pivots; and the *friction* may be ſtill diminiſhed farther, by making the axles of thoſe wheels reſt upon other *friction*-wheels that turn round with them. This was long ago recommended by P. Caſatus; and experience confirms, that we ſave much power by it. Hence alſo it is, that a pulley moveable on its axis reſiſts leſs than if it were fixed. And the ſame may be obſerved of the wheels of couches, and other carriages.

From theſe principles, with a little farther help from the higher geometry, Olaus Roemer determined the figure of the teeth of wheels, that ſhould make the leaſt reſiſtance poſſible, and which ſhould be epicycloidal. And the ſame was afterwards demonſtrated by De la Hire: though, which is much to be lamented, the thing is not yet taken into practice.

Hence, in ſawing-mills, the ſides of the wooden rectangle the ſaws are fitted into, ſhould be furniſhed with roulæ, or little wheels, which would greatly leſſen the *friction*; and the like in other caſes.

FRICTION, *calculation of the quantity of*. The *friction* is a point of the utmoſt importance in machines: and by all means to be conſidered, in calculating the force thereof: yet it is generally overlooked in ſuch calculations; but this is principally becauſe its preciſe value is not known. It is not yet reduced to certain and infallible rules: ſince it depends upon the ſtructure of bodies, the form of their prominent parts and cavities, and upon their rigidity, their elaſticity, their coherence, and other circumſtances. The common method is, barely to compute the advantage, which a moving power has from the machine; either on account of its diſtance from a fixed point; or of the direction in which it acts. And in all the demonſtrations it is ſuppoſed, that the ſurfaces of bodies are perfectly ſmooth and poliſhed. Indeed the engineers expect, that in the practice they ſhould loſe part of the advantage of their force, by the *friction*: but how much, it is ſuppoſed, nothing but the practice can determine. M. Amontons, indeed, has made an attempt to ſettle, by experiment, a foundation for the preciſe calculation of the quantity of *friction*; and Mr. Parent has confirmed it, from reaſoning and geometry: but their theory, however warranted, is not generally and fully received.

M. Amontons's principle is, that the *friction* of two bodies depends on the weight, or force, wherewith they bear on each other; and only increaſes as the bodies are more ſtrongly preſſed, or applied, againſt each other, or are charged with a greater weight; and that it is a vulgar error, that the quantity of *friction* has any dependence on the bigneſs of the ſurfaces rubbed againſt each other; or that the *friction* increaſes as the ſurfaces do. Thus if a piece of wood four inches wide and one inch thick be ground, and thereby made exactly fit to the ſurface of another fixed piece of the ſame wood, it will require the ſame weight to draw it along on the ſame, whether it be laid on its broad or narrow ſide: for, though on the broad ſide there be four times the number of touching particles (*cæteris paribus*), yet each particle is preſſed with but $\frac{1}{4}$ of the weight bearing on thoſe of the narrow ſide; and ſince four times the number multiplied by $\frac{1}{4}$ of the weight is equal to $\frac{1}{1}$ of the number multiplied by four times the weight, it is plain that the effect, that is, the reſiſtance, is equal in both caſes, and therefore requires the ſame force to overcome it.

Upon the firſt propoſal of this paradox, M. de la Hire had recourſe to experiments; which ſucceeded much in favour of the new ſyſtem. He laid ſeveral pieces of tough wood on a rough table; their ſizes were unequal; but he laid weights on them, ſo as to render them all equally heavy: and he found, that the ſame preciſe force, or weight, applied to them by a little pulley was required to put each in motion, notwithſtanding all the inequality of the ſurfaces. The experiment ſucceeded in the ſame manner in pieces of marble, laid on a marble table. Upon this M. de la Hire betook himſelf to the rationale of the thing; and has given us a phyſical ſolution of the effect. And M. Amontons has ſettled a calculus of the value of

friction; and the loſs ſuſtained thereby in machines, on the foundation of the new principle.

In wood, iron, lead, and braſs, which are the principal materials uſed in machines, he finds the reſiſtance, cauſed by *friction*, to be nearly the ſame, when thoſe materials are anointed with oil, or other fatty matter; (but this fact has been diſputed by Muſchenbroeck, and experiments urged in proof of the contrary): and this reſiſtance, independent of the quantity of ſurface, he makes to be nearly equal to a third part of the force wherewith the bodies are preſſed againſt each other. Others have obſerved, that, if the ſurfaces be hard and well poliſhed, the *friction* will be leſs than a third part of the weight; but if the parts be ſoft or rugged, it will be much greater. Let a very ſmooth cylinder of wood AB, *Tab.* III. *Mechanics, fig.* 44. be laid on two well-poliſhed and oiled or greaſed ſupporters C and D, and be charged with the weight of two pounds in the two equal balls G, H; it will require an additional weight *x* (equal to about a third part of the two pounds) to give motion to, or overcome the *friction* of the ſaid cylinder. But this additional weight, as it cauſes a greater preſſure of the cylinder, will increaſe the *friction*, and require the addition of another weight *y*, equal to a third part of its own; for the ſame reaſon the weight *y*, will require another *z* a third part of two pounds and ſo on *ad infinitum*. Therefore if the *friction* is preciſely equal to a third of the weight, the firſt weight with all the additional ones viz. *x*, *y*, *z*, &c. will be a ſeries of numbers in geometrical progreſſion decreaſing: and the ſum of all theſe terms, omitting the firſt, *i*, *e*. the ſum of the infinite number of additional weights *x*+*y*+*z* &c. is equal to one pound: ſo that if the weight of the cylinder be inconſiderable, the way to overcome the *friction* will be to double the power G or H at once.

But if the cylinder moved on the two ſmall gudgeons E and F, or on a ſmall axis, the *friction* would be abated in the ſame proportion as the diameter of theſe gudgeons is leſs than the diameter of the cylinder, becauſe in this caſe the parts on which the cylinder moves and rubs will have leſs velocity than the power which moves it in the ſame proportion. See WHEEL-*Carriages*.

The above recited hypotheſis of M. Amontons has been adopted and confirmed by M. Camus, Deſaguliers and others. In order to eſtimate the quantity of *friction* in any engine, begin at the power and conſider the velocity and the weight at the firſt rubbing part, and determine the quantity of *friction* by the foregoing principles; then proceed to the next rubbing part, finding the *friction* there, &c. Mr. Emerſon, in his Principles of Mechanics, deduces from experiments the following remarks relating to the quantity of *friction*: when a cubic piece of ſoft wood of eight pounds weight, moves upon a ſmooth plane of ſoft wood, at the rate of three feet per ſecond, its *friction* is about one third of the weight; but if it be rough, the *friction* is little leſs than half the weight: on the ſame ſuppoſition, when both the pieces of wood are very ſmooth, the *friction* is about one fourth of the weight: the *friction* of ſoft wood on hard, or of hard wood upon ſoft, is one fifth or one half of the weight; of hard wood upon hard wood one ſeventh or one eighth; of poliſhed ſteel moving on ſteel or pewter one fourth; moving on copper or lead, one fifth of the weight. He obſerves in general, that metals of the ſame ſort have more *friction* than thoſe of different ſorts; that lead makes much reſiſtance; that iron or ſteel running in braſs makes the leaſt *friction* of any; and that metals oiled make the *friction* leſs than when poliſhed, and twice as little as when unpoliſhed. Deſaguliers obſerves that, in Monſ. Camus's experiments on ſmall models of ſledges in actual motion, there are more caſes wherein the *friction* is leſs than where it is more than one third of the weight. See a table, exhibiting the *friction* between various ſubſtances, formed from his experiments in Deſ. Exp. Phil. vol. i. p. 193, &c.

Beſide the preſſion, the magnitude whereof determines that of the *friction*, there is another circumſtance to be conſidered; viz. the velocity. The *friction* is the greater, and the more difficult to ſurmount, as the parts are rubbed againſt each other with the greater ſwiftneſs; ſo that this velocity muſt be compared with that of the power neceſſary to move the machine, and overcome the *friction*. If the velocity of the power be double that of the parts rubbed, it acquires, by that means, an advantage that makes it double; or, which amounts to the ſame, it diminiſhes the contrary force of *friction* by one half, and reduces it to a ſixth part of the weight, or preſſion. But this velocity M. Amontons only conſiders as a circumſtance that augments or diminiſhes the effect of the preſſion, i. e. the difficulty of the motion; ſo that the *friction* ſtill follows the proportion of the weight. Only, we are hereby directed to diſpoſe the parts of machines that rub againſt each other, in ſuch manner, as that they may have the leaſt velocity poſſible: and thus the diameter of the axis of a wheel ſhould be as ſmall as poſſible, with regard to that of the wheel; in that the leſſer the axis, the ſlower will be the motion of the ſurfaces rubbing againſt each other; ſince the velocity of a circular motion always goes diminiſhing from the circumference to the centre: and, for the ſame reaſon, the teeth of dented wheels ſhould be as ſmall and as thin as poſſible; for a tooth catching on a notch, &c. rubs one of its ſides againſt a ſurface equal to its own; and is to diſengage itſelf, in a certain time, by paſſing over a ſpace equal to the ſurface; conſequently, the leſſer the ſurface, the leſs ſpace it has to move; the ſmalneſs of the ſurface diminiſhing the reſiſtance of the *friction*; not as it is a leſs ſurface that rubs, but as there is a leſs ſpace to move. The following general propoſition may be deduced from the preceding remarks viz. That the reſiſtances ariſing from *friction* are to one another in a ratio compounded of the preſſures of the rubbing parts, and the times or velocities of their motions.

But, notwithſtanding all the confirmations and illuſtrations of this theory of *friction*, the public, or even the academy itſelf where it was propoſed, could not be brought fully to acquieſce in it. Muſchenbroek and the abbé Nollet have concluded from experiments that the *friction* of bodies depends on the quantity of their ſurface as well as their weight. Introd. ad Phil. Nat. vol. i. c. 9. and Lect. Phyſ. Exp. tom. i. p. 241. There is ſcarce any ſubject of experiment, with regard to which different perſons have formed ſuch various concluſions, ſo that the nature and laws of *friction* are not yet ſufficiently clear and deciſive. It is granted, that the preſſion has a great effect, and is, in many caſes, the only thing to be conſidered in *friction*: but it will be hard to perſuade us abſolutely to exclude the conſideration of the ſurface. In effect, the contrary ſeems capable of metaphyſical demonſtration.

If two bodies, with plain ſurfaces, ſuppoſed infinitely hard, and poliſhed, be moved along each other, the *friction* will be none or infinitely ſmall; but if, in lieu of ſuch ſuppoſition, which has no place in nature, we ſuppoſe two bodies, with rough uneven ſurfaces, the difficulty of moving one of them on the other muſt either ariſe from this; that the firſt is to be raiſed, in order to diſengage the parts catched or locked in the ſecond; or that the parts muſt be broken, and worn off; or both. In the firſt caſe, the difficulty of raiſing one of the bodies makes that of the motion; and of conſequence the *friction* ariſes wholly from the weight, or preſſion; and the ſurface has nothing to do in it.

In the ſecond caſe, the magnitude of the ſurface would be all; were it poſſible this ſecond caſe could be abſolutely abſtracted from the firſt; *i*. *e*. could the parts of one body be rubbed and worn againſt thoſe of the other, without raiſing one of them; it being viſible, that a greater number of parts to be broken would make a greater reſiſtance than a leſs: but as in practice we never rub, or grind, without raiſing the body, the reſiſtance ariſing from the greatneſs of the ſurface in the ſecond caſe, is always combined with that from the preſſion; whereas, in the former caſe, that ariſing from the preſſion may be alone and uncompounded.

Add, that what is worn off a body, is ordinarily very little, with regard to the great number of times the body muſt have been raiſed during the *friction*, and all the little heights added together, which the body muſt have been raiſed to.

Hence, as the reſiſtance from preſſion may be *ſingle*; and as the ſame always accompanies that ariſing from the magnitude of the ſurfaces, and is uſually much the more conſiderable of the two, when it does accompany it: for theſe reaſons, in moſt of the experiments that are made, it is the only one perceived, and the only one that needs to be conſidered.

But then, as it is poſſible, in certain caſes, for the preſſion to be very ſlender, and the number of parts to be rubbed, very great, it muſt be owned, there are caſes wherein the *friction* follows, very ſenſibly, the proportion of the ſurfaces.

Dr. Deſaguliers has treated fully of the *friction* of engines, carriages, &c. See his Courſe of Experim. Philoſ. vol. i. p. 133 to 138. and p. 182 to 254. ſee alſo p. 458 to 460.

FRICTION *of the parts of fluids*. See RESISTANCE, and RETARDATION *of fluids*.

FRICTION *of ropes*. See CORDAGE and ROPES.

FRICTION *of wheel-carriages*. See WHEEL-*carriages*.

FRICTION, in *Medicine* and *Surgery*, denotes the act of rubbing a diſeaſed part with oils, unguents, or other matters; in order to eaſe, relieve, and cure it.

Frictions are much uſed of late in venereal caſes. They prefer the applying of mercury externally by way of *friction*, to that of giving it internally, to raiſe a ſalivation.

There are alſo *frictions* with the fleſh-bruſh, a linen cloth, or the hand only: for the effect of which laſt, ſee STROAKING.

Frictions of any kind are a ſort of exerciſe which contributes greatly to health; as they excite and ſtir up the natural warmth, divert defluxions, promote perſpiration, open the pores of the ſkin, and carry off ſtagnant humours.

The fleſh-bruſh, Dr. Cheyne obſerves, is an exerciſe extremely uſeful for promoting a full and free perſpiration and circulation. Every body knows the effect of currying horſes; that it makes them ſleek, gay, lively, and active; ſo as even to be judged equivalent to half the feeding.

This it can no otherwiſe effect, but by aſſiſting nature to throw off the recrement of the juices, which ſtop the free circulation, and, by conſtant *friction*, irritation, and ſtimulation, to bring the blood and ſpirits to the parts moſt diſtant from the ſeat of heat and motion; and ſo plump up the ſuperficial muſcles. And the ſame effect it would have in other creatures, and man himſelf, if managed in the ſame manner, and with the ſame care and regularity.

Perſons, therefore, of weak nerves, and ſedentary lives, would do well to ſupply the want of other exerciſe with ſpending half an hour morning, and night, in currying and rubbing their whole body, eſpecially their limbs, with a fleſh-bruſh. But this means of health is moſt advantageouſly uſed when the *prima via* are moſt empty.

FRICTION, or rather FRIXION, in *Chemiſtry*, is the ſame with what in cookery we call *frying*; viz. the coction of certain matters in a pan, with the addition of ſome unctuous thing, as oil, *fat*, &c.

The *friction* of medicines is performed over a ſlow, moderate fire; and that of foods over a quick one.

FRIDAY, the ſixth day of the WEEK ſo called from Friga, a goddeſs worſhipped by the Saxons on this day. It is a faſt-day in the church of England, in memory of our Saviour's crucifixion, unleſs Chriſtmas-day happens to fall on *friday*, which is always a feſtival.

FRIDAY, *Good*. See PASSION-*Week*.

FRIDSTOLL, or FRITHSTOW, of the Saxon *frid*, peace, and *ſtol*, ſeat, in our *ancient Writers*, ſignifies a ſeat, chair, or place of peace, where criminals might find ſafety and protection.

In the charter of immunities confirmed to the church of St. Peter in York, ann. 5 H. VII. it is explained by *Cathedra quietudinis & pacis*.

Of theſe there were many in England; but the moſt famous was at Beverley, which had this inſcription, *Hæc ſedes lapidea* Freedſtol *dicitur*, i. e. Pacis Cathedra *ad quam reus fugiendo pervenions, omnimodam habet ſecuritatem*. Camden.

FRIENDLESS *Man*, was the old Saxon name for him whom we call an outlaw.

The reaſon is, becauſe he was, upon his excluſion from the king's peace and protection, denied all help of friends, after certain days. *Nam foris fecit amicos*.

FRIENDS *Alien*. See ALIEN.

FRIESLANDERS, in *Eccleſiaſtical Hiſtory*, a ſect of moderate ANABAPTISTS, deriving their name from *Frieſland*, the country which they inhabit. See WATERLANDIANS.

FRIEZE. FRIZE, or FREEZE. See FREEZE.

FRIGATE, in *Sea Affairs*, a ſhip of war, uſually of two decks, light built, deſigned for ſwift ſailing. When it hath but one deck, and conſequently is of a ſmaller ſize, they call her a light *frigate*. See RATE.

Frigates mount from twenty to thirty-eight guns, and are eſteemed excellent cruizers. The name was formerly known only in the Mediterranean, and applied to a long kind of veſſel navigated in that ſea with ſails and oars. The Engliſh were the firſt who appeared on the ocean with theſe ſhips, and equipped them for war as well as for commerce.

FRIGATE-*built* denotes the diſpoſition of the decks of ſuch merchant ſhips as have a deſcent of four or five ſteps from the quarter deck and fore-caſtle into the waiſt, in contradiſtinction to thoſe whoſe decks are on a continued line for the whole length of the ſhip, which are called galley-built. See *Flush*-DECK.

FRIGATOON, a Venetian veſſel, commonly uſed in the Adriatic, built with a ſquare ſtern, and without any foremaſt, having only a main-maſt, mizen-maſt, and bow-ſprit.

FRIGERATORY, among *Builders*, denotes a place intended to keep things cool in ſummer.

FRIGHT. This paſſion has been known not only to cauſe but to cure diſeaſes. Mr. Boyle mentions agues, gout, and ſciatica, cured by this means. See Works abr. p. 82, &c.

It is a commonly known cure for the hiccough, to put the patient in a ſudden *fright*.

FRIGID, FRIGIDUS, *cold*, is variouſly uſed. A *frigid* ſtyle, is a low, jejune manner of diction; wanting force, warmth of imagination, figures of ſpeech, &c.

FRIGID *Zone*, or *Frozen Zone*, in *Geography*. See ZONE.

FRIGIDITY is alſo uſed in the ſame ſenſe with IMPOTENCE.

FRIGORIFIC, of *frigus*, *cold*, and *facio*, *I make*, in *Phyſics*, ſomething that occaſions cold.

Some philoſophers, particularly Gaſſendus, and other corpuſcularians, denying cold to be a mere privation, or abſence of heat, contend that there are actual *frigorific* corpuſcles or particles as well as fiery ones: whence proceed COLD and HEAT. But later philoſophers allow of no other *frigorific* particles beſide thoſe nitrous ſalts, which float in the air in cold weather, and occaſion FREEZING.

FRILL, in *Falconry*, when a hawk trembles or ſhivers, they ſay ſhe *frills*. Dict. Ruſt.

FRINGE-*tree*. See SNOW-*drop-tree*.

FRINGILLA, in the *Linnæan Syſtem of Ornithology*, the name of a large genus of birds of the general order of the paſſeres. The diſtinguiſhing characters of this genus are theſe: the tongue is ſmooth and even, the beak is of a conic, ſtraight, ſharp-pointed figure, and one mandible receives the other into the ſinus of its baſis. Of this genus are the CHAFFINCH, GOLD-*finch*, SPARROW, LINNET, &c.

FRINGILLAGO, in *Ornithology*, a name by which ſome have called the whole genus of the titmouſe; but others have reſtrained it only to one ſpecies of them, which is the common larger kind called by us the ox-eye. This is much larger than any of the others, weighing near an ounce, whereas they ſeldom exceed three drams. Its head and throat are black, the cheeks white, the back green, the belly of a yelloviſh green, divided in the middle by a bed of black, which extends to the vent: the rump is of a bluiſh grey. The quill feathers are duſky, edged partly with blue, partly with white; the coverts blue, the greater tip with white. The exterior ſides of the outmoſt feathers of the tail are white, of the others bluiſh; their interior ſides duſky, the legs of a lead colour: the toes are divided to the origin; and the back toe of the whole genus of titmouſe is large and ſtrong. This bird builds in hollow trees, and lays ten eggs, though it ſometimes viſits the gardens and does great miſchief to the fruit. It has three cheatful notes which it begins to utter in the month of February. Pennant. Ray's Ornithol. p. 174.

FRINGILLAGO *Americana cærulea*, in *Ornithology*, a name given by Mr. Ray to the American titmouſe, otherwiſe known by its Braſilian name *guiracuia*.

FRINGILLARIUS *Acceptor*, in *Ornithology*, the name of a ſpecies of hawk called by ſome *niſus*, and in Engliſh the *ſparrow*-HAWK.

FRIPPERY, a French term ſometimes uſed in our language; properly importing the trade, or traffick, of old ſecond-hand cloaths and goods.

The word is alſo uſed for the place where ſuch ſort of commerce is carried on, and even for the commodities themſelves. The company of *Fripiers*, or *Fripperers*, at Paris, form a regular corporation, of an ancient ſtanding; and make a conſiderable figure among the companies of that city.

FRIST, a term among *Merchants* for ſelling goods upon credit.

FRIT, or FRITT, in the *Glaſs Manufacture*, is the matter, or ingredients, whereof glaſs is to be made; when they have been calcined, or baked in a furnace.

A ſalt drawn from the aſhes of the plant kali, or from fern, or other plants mixed with ſand, or flint, and baked together, makes an opake maſs, called by glaſſmen *frit*; probably from the Italian *frittare*, to fry, or becauſe the frit, when melted, runs into lumps, like fritters, called by the Italians *fritelli*.

Frit, by the ancients, was called *ammonitrum*, or *ammonitrum*, of ἄμμος, ſand, and νίτρον, nitre: under which name it is deſcribed by Pliny thus: fine ſand from the Volturnian ſea, mixed with three times the quantity of nitre, and melted, makes a maſs called *ammonitrum*; which, being rebaked, makes pure glaſs. Hiſt. Nat. lib. xxxvi. cap. 26.

Frit, Neri obſerves, is only the calx of the materials which make glaſs: which though they might be melted, and glaſs be made, without thus calcining them, yet it would take up much more time. This calcining, or making, of *frit*, ſerves to mix and incorporate the materials together, and to evaporate all the ſuperfluous humidity. The *frit*, once made, is readily fuſed, and turned into glaſs.

There are three kinds of *frits*; the firſt, *cryſtal frit*, or that for cryſtal metal; made with ſalt of pulvertine and ſand.

The fecond, and ordinary *frit*, is made of the bare afhes of pulverine, or borillia, without extracting the falt from them. This makes the ordinary white, or cryftal metal.

The third is *frit* for green glaffes, made of common afhes, without any preparation. This laft *frit* will require ten or twelve hours baking.

The materials in each are to be finely powdered, waſhed and fearced; then equally mixed, and frequently ſtirred together in the melting pot. For the reſt, ſee GLASS, and CRYSTAL.

FRITBURGH. See FRIBURGH.

FRITH. See FRYTH.

FRITHGILD, was anciently the ſame with what we now call a *guild*, or *fraternity*, or *company*. See GILD.

FRITILLARIA *craſſa*. See SWALLOW-*wort*.

FRITILLARY, *fritillaria*, the *checquered tulip*, and *crown imperial*, in *Botany*; a genus of the *hexandria monogynia* claſs; its characters are theſe: the flower has no empalement, but is bell-ſhaped and hath ſix oblong petals; in the hollow at the baſe of each petal is ſituated a *nectarium*: and the flower hath ſix *ſtamina* ſtanding near the ſtyle. In the centre is ſituated an oblong three-cornered germen, which afterwards becomes an oblong capſule with three lobes, having three cells, which are filled with flat ſeeds ranged in a double order. Linnæus reckons five, and Miller nine ſpecies. There are vaſt varieties in the colours of the flower, when the plants are carefully propagated from ſeeds. They are by ſome propagated by roots, but the method by ſeeds is greatly preferable, as it produces much the greater number of roots, as well as the better flowers. The ſeeds for this ſhould be ſaved from the fineſt flowers, and ſown on ſome light freſh earth in flat ſhallow pans, or boxes with holes at the bottom, kept open by tile-ſtreds to let out the moiſture. The ſeeds muſt be ſown pretty thick, and covered with a quarter of an inch of earth: this is to be done in the beginning of Auguſt. The pans or boxes are then to be ſet in a place where they may have the morning's ſun, till about eleven o'clock, and if the ſeaſon proves dry, they muſt be watered, and always carefully kept clear of weeds.

Toward the latter end of September the boxes muſt be removed into a warmer ſituation, and placed under ſhelter of a hedge or under a ſouth wall, and they are here to remain till the middle of March, by which time the plants will be come up an inch high. They are now to be removed into a ſhady ſituation, and are to remain there the whole ſummer. About the beginning of Auguſt, a bed of freſh earth is to be prepared, on which the earth of the pans and boxes containing the roots of the plants is to be ſtrewed, after the leaves are all dead: this is to be covered one fourth of an inch thick with fine freſh earth evenly ſifted on, and in this ſtate they are to remain till they flower, which is generally the third year from the ſowing. When they are in flower, the fineſt kinds ſhould be marked with ſticks, and their roots planted out into ſeparate beds.

As ſoon as the leaves are decayed they ſhould be carefully weeded, and thin off-ſets taken up and tranſplanted. Miller.

For an account of the other ſpecies of this genus, ſee CROWN *imperial*.

FRIXION. See FRICTION.

FRIZE, or FRIEZE, in *Architecture*, a part of the entablature of columns, more uſually written and pronounced FREZE.

FRIZE, or FREEZE, in *Commerce*, a kind of woollen cloth, or ſtuff for winter wear, being *friſed*, or knapt, on one ſide; whence, in all probability, it derives its name.

Of *friſes*, ſome are croſſed, others not croſſed: the former are chiefly of Engliſh manufacture, the latter of Iriſh.

FRIZING *of cloth*, a term in the *Woollen Manufactory*, applied to the forming of the knap of a cloth, or ſtuff, into a number of little hard burrs, or prominences, covering almoſt the whole ground thereof.

Some cloths are only *friſed* on the back-ſide, as black cloths; others on the right ſide, as coloured and mixed cloths, rateens, bays, friſes, &c.

Friſing may be performed two ways; one with the hand, i. e. by means of two workmen, who conduct a kind of plank that ſerves as a *friſing* inſtrument.

The other way is by a mill, worked either by water, or a horſe; or, ſometimes, by men. This latter is eſteemed the better way of *friſing*, becauſe the motion being uniform and regular, the little knobs of the *friſing* are formed more equably and regularly.

The ſtructure of this uſeful machine is as follows:

The three principal parts are, the *friſer*, or criſper; the *friſing*-table; and the drawer, or beam. The two firſt are two equal planks, or boards, each about ten feet long, and fifteen inches broad; differing only in this, that the *friſing*-table is lined or covered with a kind of coarſe woollen ſtuff, of a rough, ſturdy knap, and that the *friſer* is incruſtated with a kind of cement, compoſed of glue, gum Arabic, and yellow ſand, with a little aqua vitæ, or urine. The beam or drawer, thus called, becauſe it draws the ſtuff from between the *friſer* and *friſing*-table, is a wooden roller, beſet all over with little fine, ſhort points or ends of wire, like thoſe of cards uſed in carding of wool.

The diſpoſitionand uſe of the machine are thus: the table ſtands immoveable, and bears or ſuſtains the cloth to be *friſed*, which is laid with that ſide uppermoſt on which the knap is to be raiſed. Over the table is placed the *friſer*, at ſuch diſtance from it as to give room for the ſtuff to be paſſed between them; ſo that the *friſer*, having a very ſlow, ſemi-circular motion, meeting the long hairs or knap of the cloth, twiſts and rolls them into little knobs or burrs, while, at the ſame time, the drawer, which is continually turning, draws away the ſtuff from under the *friſer*, and winds it over its own points.

All that the workman has to do while the machine is going, is to ſtretch the ſtuff on the table as faſt as the drawer takes it off, and, from time to time, to take off the ſtuff from the points of the drawer.

It has already been obſerved, that the *friſing*-table is lined with ſtuff of a ſhort, ſtiff, ſtubby knap; the uſe whereof is, to detain the cloth between the table and *friſer*, long enough for the grain to be formed, that the driver may not take it away too readily; which otherwiſe muſt be the caſe, inaſmuch as it is not held by any thing at the other end.

It were needleſs to ſay any thing particular of the manner of *friſing* ſtuffs with the hand, it being the aim of the workmen to imitate, as near as they can, with their wooden inſtrument, the ſlow, equable, and circular motion of this machine. It needs only be added, that their *friſer* is but about two feet long, and one broad; and that, to form the knap more eaſily, they moiſten the ſurface of the ſtuff lightly with water, mingled with whites of eggs, or honey.

FRIZONE, in *Ornithology*, a name by which many call the COCCOTHRAUSTES or groſs-beak, called alſo in Engliſh the hawfinch.

FROBENIUS's *ætherial ſpirit*. See ÆTHER and SPIRIT.

FROG, *rana*, in *Zoology*, a genus of reptiles in the claſs of amphibious animals: the characters of it are, that the body is naked, without a tail, and furniſhed with four legs.

The feet of the *frogs* are webbed, for the better ſwimming, and it has very ſtrong muſcles in the hinder part of its body to aſſiſt it in leaping. The lungs of the *frog* are different from thoſe of all other animals: they are only a ſort of membranaceous bladders, with ſeveral tubercles, by means of which they reſemble the fruit of the firs, or pines: theſe, when once inflated, do not immediately become flaccid, as in other animals, but remain in that ſtate as long as the creature pleaſes. The creature can remain a long time under water, and has been kept ſo for ſeveral days, by tying it down, and received no hurt from it. It is a very long-lived animal; and even if its belly be opened, and the inteſtines and all the viſcera taken out, it will continueſts leaping, and all its other motions, as if nothing had happened to it, for a conſiderable time; but if the nerve of one of the hinder legs be cut, it inſtantly loſes all power of uſing that limb. Ray's Synop. Quad. p. 247.

FROGS, *the generation of*, was very nicely inquired into by the ſagacious Leewenhoek. He found, by repeated obſervations, that the male in copulation only ſits upon the female, not being joined to her, nor having any apparent penis. At the time that the female *frog* drops her ſpawn, the male alſo throws out his ſemen, which is to be placed under the eggs, as the ſemen of fiſhes that want the penis is caſt under the eggs or ſpawn of their females, that the animalcules in it may impregnate the eggs. The animalcule in the male-feed has its way to make into a certain point of the egg of the female, or elſe that egg is unfruitful; and this is the reaſon why the animalcules in the male ſemen are ſo prodigiouſly more numerous than the eggs of the female, becauſe vaſt multitudes of them muſt neceſſarily be loſt. The teſticles and vaſa deferentia of *frogs* are very evident to any one uſed to anatomical inquiries, on opening the creature; and theſe contain vaſt numbers of very vigorous animalcules at the time when the creature is to produce its young, which is in April, but at other times they are not ſo numerous or lively.

The *frog* differs from all creatures in the manner of its generation. It no way reſembles any of the quadrupeds in this particular; and though in ſome ſort it approaches to the nature of fiſh, yet it differs from them alſo in many things. The egg of the *frog* is a ſmall black ſpot, enveloped

enveloped in a mucilaginous ſubſtance; in this egg is contained the embryo *frog*, which, on the breaking of the egg in hatching, comes forth in the form of a tadpole. This young animal is for ſome time nouriſhed by the gelatinous matter which envelopes the eggs, but it does not conſume the whole of it; for the particles of water making way by degrees into it, divide its parts, and it ſoon becomes expanded, frees itſelf from the living animals, and floats on the ſurface of the water, or at a ſmall depth in it, in form of a thin cloud: this, though it now no longer ſerves for food to the young creature, is however of ſome ſervice to it, ſerving it as an aſylum, or place of reſt and ſafety, when tired with ſwimming.

The egg of the *frog*, therefore, is, in ſome degree, analogous to that of an inſect of the winged kind, which is to go through a metamorphoſis before it arrives at its perfect ſtate; for it hatches into the tadpole, as the egg of a butterfly into a caterpillar, and arrives at that its ultimate ſtate, after a determinate time ſpent in the other. In this it differs from the generation of fiſhes, the eggs of whoſe ſpawn hatch into perfect fiſhes, which go through no change; and it differs from all in the gelatinous ſubſtance which envelopes the egg, and ſerves as the firſt food to the fœtus.

The eggs are indeed, when nicely examined, found to be incloſed in a double liquor, or more pellucid and thin one within the gelatinous one, which ſerves as the general covering to the whole ſeries of eggs; and it is this thin one which it principally feeds on when firſt hatched, and which ſerves to the ſame purpoſe as the white of an egg in the fowl kind. Ray, *ut ſupra*.

This creature bears the experiments of the air-pump better than moſt other animals. It will breathe ſome time after the extraction of the air, but at length the viſible motion of the throat will ceaſe, and the body ſwell a little. After three hours lying in this condition, when no farther ſign of life appears, if the animal be placed in the open air, a few hours will recover it to its former life and vigour. The ſame animal put into a receiver exhauſted of the air, but nearly filled with water, will live many hours under the water, and ſeem to reſpire, but in five or ſix hours it will die. The larger and luſtier *frogs* live longer than the young ones in the receiver. Phil. Tranſ. N° 62.

The FROG affords the curious in microſcopic obſervations a very beautiful view of the circulation of the blood; but the method of examining it to advantage was never hit upon till the contrivance of the late ingenious Dr. Stuart for that purpoſe. This he did by the ſolar microſcope in the following manner. The looking-glaſs, tube, and convex lens, are the ſame in this, as in the common ſolar microſcope; but inſtead of the little pocket microſcope of Wilſon, he uſed the belly-part of the common large reflecting one, fixed horizontally on a pedeſtal, juſt at an equal height with the tube. This ſtands on a little ſhelf made to ſupport it; and to its ſnout, which lies on a level with the tube, the magniſiers are ſcrewed: the object being extended and faſtened with ſtrings and pins on a frame contrived for that purpoſe, is applied between the tube and the magniſier, whereby the ſun's rays, reflected from the looking-glaſs, through the tube, upon the object, paſs on through the magniſier, and exhibit upon the ſcreen an image of the object moſt prodigiouſly enlarged. Baker's Microſc. p. 132.

To view a *frog* with this apparatus, the ſkin of the belly is to be opened from near the anus to the throat, and then giving it a little ſnip ſideways both at the top and bottom, and ſticking a fiſh-hook into each corner of the ſkin, it was eaſily extended before the microſcope, and ſhewed on the ſcreen the moſt beautiful view imaginable of the veins and arteries of the ſkin, with the blood circulating through them. In the arteries thus viewed, the blood is ſeen to ſtop, and recede a little at every pulſation by the dilatation, and ruſh forcibly on again by the contraction of the heart: while in the veins it ever kept the ſame equable and uniform *current*, with a ſurpeiſing rapidity; and when the ſcreen was removed farther back, and the object by that means more enlarged, the alternate expanſion and contraction of the ſides of the arteries were very viſible. After this, the abdomen of the *frog* being opened, and the muſcles of it being extended before the microſcope in the ſame manner as the ſkin was, the ſtructure of theſe muſcles is beautifully ſeen, being all made up of bundles of tranſparent ſtrings of fibres, all lying parallel to one another, and joined by a common membrane.

Theſe ſtrings or fibres appeared alſo through their whole length made up of roundiſh veſicles, and reſembled ruſhes divided longitudinally; but there is no certainty of any circulation being ſeen in theſe.

When this has been ſufficiently examined, a part of the creature's guts being pulled out and extended with the meſentery, there is ſeen the fineſt of all views of the circulation of the blood. Words are not able to deſcribe this wonderful ſcene. The blood is ſeen paſſing through numberleſs veſſels at one and the ſame inſtant, in ſome one way, and in others directly the contrary. Several of the veſſels are thus magniſied to more than an inch in diameter, and the globules of the blood rolling through them, appear near as large as pepper-corns; while in many of the minuteſt veſſels only ſingle globules were able to find their paſſage, and that too by changing their ſhape into an oblong ſpheroid. The pulſation and acceleration of the blood in the arteries are thus alſo very beautifully ſeen. As the animal under examination grows languid and near expiring, the blood in the arteries will often ſtop on a ſudden, and ſeem as if it were coagulating, and will then run back for ſome time; after which it will again recover its natural courſe with a great deal of rapidity. A due conſideration of theſe particulars may poſſibly account for the intermiſſions, ſtarts, and irregularities, in the pulſe of perſons near death. Baker's Microſcope, p. 136.

FROG, among *Farriers*, the ſame with thruſh. See THRUSH.

FROG's *bit*, in *Botany*. See HYDROCHARIS.

FROG, *built*. See BULL-*frog*.

FROG-*fiſh*, in *Ichthyology*, an Engliſh name for the RANA-PISCATRIX, or LOPHIUS. See SEA-*Devil*.

FROG-*fiſh of Surinam*, is produced by the tranſformation of a *frog* into a fiſh. The *frog*, in its firſt ſtate, is ſpotted with brown, yellow, and green, but paler on the belly; the hinder feet are webbed like thoſe of a gooſe, but the fore-feet are without webs: the firſt change this *frog* undergoes is by the growing out of a tail; after which it gradually acquires the ſhape of a fiſh, the two fore-feet decreaſing and periſhing by degrees, and then the hinder legs; and, at length, the *frog* is changed into a perfect fiſh. The Indians and Europeans of Surinam call theſe fiſhes jakies; they are cartilaginous, and of a ſubſtance like our *muſtela*, and very delicate food. A bone or cartilage runs down the back, with ſmall bones all over the body, which is divided into equal parts; they are adorned with beautiful ſcales, are firſt of a dark-iſh colour, and afterwards grey. See an account of the ſeveral tranſformations of this *frog*, illuſtrated with drawings, and of the tranſformation of fiſhes into *frogs*, in Phil. Tranſ. vol. ii. p. 2. art. 60. p. 653, &c.

Tree FROG. See RANUCULUS *viridis*.

FRONDES, among *Botaniſts*. See LEAF.

FRONT, the forehead, or that part of the face above the eyebrows.

The word is formed of the Latin *frons*; and that from the Greek φρονεω, *to think, perceive*; of φρην, *mens, the mind, thought*. Martinius, to make out this etymology, obſerves, that from the forehead of a perſon we perceive what he is, what he is capable of, and what he thinks of. Du Laurens chuſes to derive it from *ferre*, becauſe it bears the marks of what we have in our head.

FRONT is alſo uſed where ſeveral perſons, or things, are ranged ſide by ſide, and ſhew their *front*, or fore parts.

FRONT, in *Architecture*, denotes the principal face, or ſide of a building; or that preſented to their chief aſpect, or view.

FRONT, in *Fortification*. See FACE and TENAILLE.

FRONT *of a regiment*, in *Military Language*, denotes the foremoſt rank of a battalion, ſquadron, or any other body of men.

To *front* every way, is when the men are faced to all ſides. See FILE-*leaders*.

FRONT *of a camp* is the line that determines its extent, and in which are placed the colours and ſtandards of the troops that occupy the CAMP.

FRONT, in *Perſpective*, a projection or repreſentation of the face, or fore-part of an object, or of that part directly oppoſite to the eye; called alſo, and more uſually, ORTHOGRAPHY.

FRONT, *line of the*. See LINE.

FRONT *ſcale*. See SCALE.

FRONTAL, in *Architecture*, a little fronton or pediment, ſometimes placed over a ſmall door or window.

FRONTAL, FRONTLET, or *Brow-band*, is alſo uſed in ſpeaking of the Jewiſh ceremonies.

This *frontal* conſiſts of four ſeveral pieces of vellum, on each whereof is written ſome text of ſcripture: they are all laid on a piece of a black calf's leather, with thongs to tie it by. The Jews apply the leather with the vellum on their foreheads, in the ſynagogue, and tie it round the head with the thongs.

FRONTALE *os*, in *Anatomy*. See *Os* FRONTIS.

FRONTALE, or FRONTAL, in *Medicine*, an external form of remedy, applied on the forehead and temples, with a bandage, for the cure of the head-ach, megrim, rheums, defluxions on the eyes, &c.

Frontali

Frontals are compoſed of *roſes*, elder flowers, betony, marjoram, lavender, camphire, &c. wrapped in linen cloth, and applied over the forehead and temples.

There are alſo *frontals* in manner of liniments, made of unguentum populeum, and extract of opium, or paſtes, powders, ſeeds, &c.

In *frontals* applied to eaſe the violence of the head-ach, in the heights of fevers, they frequently mix the kernels of cherries.

FRONTALES, in *Anatomy*, two muſcles one on each ſide the forehead, commonly ſuppoſed to ſpring from the ſkull, but not known to ariſe from the occipital muſcles; or rather, it appears that the *frontales* and occipitales, are only one continued digaſtric muſcle, on each ſide, moving the ſcalp and ſkin of the forehead and eyebrows. See *Tab. Anat. (Muſcul.) fig.* 1. N° 1.

The *frontales* begin to be thus denominated after they have begun to paſs the coronal future, with fibres paſſing obliquely to the eyebrows, where they terminate, and in the lower part of the ſkin of the forehead.

They have each two appendages: the ſuperior, or external, is commonly fixed to the bone of the noſe; the lower is fixed to the os frontis, and is, by Volcherus Coiter, made a diſtinct muſcle, and called CORRUGATOR, from its uſe in drawing the eyebrows to each other, and wrinkling the forehead.

FRONTATED, a term uſed by *Botaniſts*, to expreſs that the petalum, or leaf of a flower, grows broader and broader; and at laſt, perhaps, terminates in a right line; in oppoſition to *cuſpidated*, which expreſſes, that the leaves terminate in a point.

FRONTEVAUX, *order of*. See FONTEVRAUD.

FRONTIER, the border, confine, or extreme, of a kingdom, or province; which the enemies find in front when they would enter the ſame. Thus we ſay, a *frontier* town, *frontier* province, &c. *Frontiers* were anciently called *marches*.

The word is derived from the French *frontiere*, and that of the Latin *frontaria*; as being a kind of front oppoſed to the enemy. Skinner derives *frontier* from *front*; inaſmuch as the *frontiers* is the exterior, and moſt advanced part of a ſtate; as the front *is* that of the face of a man.

FRONTIS *os*, in *Anatomy*, the bone of the forehead. See *Tab. Anat. (Oſſeol.) fig.* 1. *lit. a.* See Os *Frontis*.

FRONTIGNIAC *wine* is ſo called, from a town of Languedoc in France, ſituated ſixteen miles ſouth-weſt of Montpelier, remarkable for producing it.

FRONTISPIECE, in *Architecture*, the portrait, or principal face, of a fine BUILDING.

The word is formed of the Latin *frontiſpicium*, q. d. *frontis hominis inſpectio*.

The *frontiſpiece* of the Louvre is the fineſt piece of architecture in France.

Hence, alſo, by a figure, we ſay, the *frontiſpiece* of a book, meaning an ornament, with an engraven title on the firſt page.

FRONTLET. See FRONTAL.

FRONTLET, *Jim*, in *Gunnery*, is a piece of a plank three inches thick, a foot long, and ſeven or eight inches high, with a round cavity underneath, to fit the outſide of the gun, and having a ſmall ſlit to ſee the object through it. It is placed upon the vent field of the gun, when it is pointed in a BATTERY.

FRONTON, in *Architecture*, an ornament, among us more uſually called PEDIMENT.

FROST, an exceſſive cold ſtate of the weather, whereby the motion and fluidity of liquors is ſuſpended; or, it is that ſtate of the air, &c. whereby fluids are converted into ICE. See COLD and FREEZING.

Metals contract in *froſt*. Monſ. Azout found, by experience, that an iron tube, twelve feet long, loſt two lines of its length, upon being expoſed to the air in a *froſty* night; but this we ſuppoſe wholly the effect of the cold. *Froſt* does not contract fluids, as was formerly imagined; on the contrary it ſwells, or dilates them, by nearly a tenth of their bulk. See ICE.

Scheffer aſſures us, that in Sweden, the *froſt* pierces into the earth two cubits, or Swediſh ells, and turns what moiſture is found therein into a whitiſh ſubſtance, like ice: he adds, the ſtanding waters freeze to a greater depth, even to three ells or more; but thoſe that have a current, leſs; and rapid waters, and bubbling ſprings, never freeze, even there.

Olearius aſſures us, that in the city of Moſcow he obſerved the earth to be cleft by the *froſt* many yards in length, and a foot broad. Scheffer mentions ſudden cracks or rifts in the ice of the lakes of Sweden, nine or ten feet deep, and many leagues long; and adds, that the rupture is made with a noiſe not leſs terrible than if many guns were diſcharged together. By ſuch means the fiſhes are furniſhed with air; ſo that they are rarely found dead.

In the great *froſt* in 1683, oaks, aſhes, walnut-trees, &c. Mr. Bobart tells us, were miſerably ſplit and cleft, ſo that one might ſee through them; and this, frequently, with terrible noiſes, like the exploſion of fire-arms; the clefts were not only in the bodies, but continued to the larger boughs, roots, &c. See an inquiry into the circumſtances and cauſes hereof in the Philoſoph. Tranſact. N° 165.

The natural hiſtories of *froſts* furniſh very extraordinary effects thereof. The trees are frequently ſcorched, and burnt up, as with the moſt exceſſive heat; of which there are divers inſtances in ſo warm a climate as that of Provence.

The cloſe of the year 1708, and the beginning of 1709, were remarkable, throughout the greateſt part of Europe, for a ſevere *froſt*. Dr. Derham ſays, it was the greateſt in degree, if not the moſt univerſal, in the memory of man: it extended throughout England, France, Germany, Denmark, Italy, &c. but it was ſcarcely felt in Scotland or Ireland. All the orange-trees, and olives, in Italy, Provence, &c. and all the walnut-trees throughout France, with an infinity of other trees, periſhed by this *froſt*. They had a kind of gangrene that grew on them; which Monſ. Gauteron takes to have been the effect of a corroſive ſalt corrupting and deſtroying their texture. He adds, there is ſo much reſemblance between the gangrene befalling plants through *froſt*, and that which the parts of animals are liable to, that they muſt have ſome analogous cauſe. Corroſive humours burn the parts of animals: and the aerial nitre condenſed has the ſame effect on the parts of plants. *Pourtrobile frigus adurat*. Memoires de l'Academie Royale de Sciences, an. 1709.

In England, the greateſt ſufferers in the animal kingdom, Dr. Derham obſerves, were birds and inſects; particularly larks, and robin-red breaſts; much the greateſt part of which periſhed. But the vegetables were far the greater ſufferers; few of the tender ſorts eſcaped; bays, hollies, roſemary, cypreſs, alaterni, phillyreas, arbutis, lauruſtines, and even furze; with moſt of the fruteſcent herbs, as lavenders, aſparagus, rue, thyme, &c. Mr. Bobart informs us, were generally deſtroyed. The ſame writer adds, that the ſap of the finer wall-fruit was ſo congealed and diſordered, that it ſtagnated in the limbs and branches, and produced diſorders like to chilblaines in human bodies, which, in many parts of trees, would turn to mortifications; and that the very buds of the finer trees, both the leaf-buds, and bloſſom-buds, were quite killed, and dried into a farinaceous matter.

Dr. Derham relates it, as a common obſervation, that vegetables ſuffered more in this winter from the ſun, than the *froſt*; in that the ſun-ſhine melting the ſnow, and opening the ground, left them more expoſed to the rigours of the enſuing night; and at a meeting of the Royal Society, it was obſerved, that the calamities which befel trees, aroſe, not purely from their being frozen, but, principally, from the winds ſhaking and rocking them, when they were ſo; which rent and parted their fibres. Phil. Tranſ N° 324.

In very cold countries meat may be preſerved by the *froſt* for ſix or ſeven months, and prove tolerable good eating. See Captain Middleton's Obſervations made in Hudſon's Bay, in the Phil. Tranſ. N° 465 ſect. 2.

In that climate the *froſt* ſeems never out of the ground, it having been found hard frozen in the two ſummer months.

Brandy and ſpirits of wine, ſet out in the open air, freeze to ſolid ice in three or four hours. Lakes and ſtanding waters, not above ten or twelve feet deep, are frozen to the ground in winter, and all the fiſh therein periſh.

But in rivers, where the current of the tide is ſtrong, the ice does not reach ſo deep, and the fiſh are preſerved.

Springs have never yet been found free from FREEZING, though lying ever ſo deep; ſo that the water uſed is melted ſnow and ice. Id. ibid.

The great power of *froſt* on vegetables is a thing ſufficiently known; but the difference between the *froſts* of a ſevere winter, and thoſe which happen in the ſpring mornings, in their effects on plants and trees, were never perfectly explained, till by Meſſ. Du Hamel, and De Buffon, in the Memoirs of the Paris Academy.

The accurate knowledge of vegetables, which is ſo material a part of agriculture, as to deſerve the attention of all who wiſh well to their country, is however a thing only to be arrived at in length of time, and by a great number of experiments, ſuch as no one man's life can give him opportunities of making; and even thoſe which have been made ſeemingly with the greateſt care and caution in one place, and have ſerved for the eſtabliſhment of rules with one author, have been found to ſucceed very differently, and to give very different ideas in another place, and to another perſon.

The *froſts* of ſevere winters are much more terrible than thoſe of the ſpring, as they bring on a privation of all the

products of the tenderer part of the vegetable world; but then they are not frequent, fuch winters happening but once perhaps in an age, and the *frofts* of the fpring are in reality greater injuries to us than thefe, as they do as great injuries, though not fo terrible as the others, and thefe are every year repeated.

In regard to trees, the great difference is this, that the *frofts* of fevere winters affect even their wood, their trunks and large branches; whereas thofe of the fpring have only power to hurt the buds.

The winter *frofts* happening at a time when moft of the trees in our woods and gardens have neither leaves, flowers, nor fruits upon them, and have their buds fo hard as to be proof againft flight injuries of weather, efpecially if the preceding fummer has not been too wet; in this ſtate, if there are no unlucky circumſtances attending, the generality of trees bear moderate winters very well; but hard *frofts*, which happen late in the winter, cauſe very great injuries even to thofe trees which they do not utterly deſtroy. Theſe are, 1. Long cracks following the direction of the fibres. 2. Parcels of dead wood, incloſed round with wood yet in a living ſtate. And, 3. That diſtemperature which the foreſters call the double blea, which is a perfect circle of blea, or ſoft white wood, which, when the tree is afterwards felled, is found covered by a circle of hard and ſolid wood. The BLEA is in its natural ſtate an outer circle of white and imperfect wood encompaſſing the hard and more perfect wood of the tree, and ſurrounded by the bark, and is eaſily diſtinguiſhed in moſt ſpecies from the hard wood or heart of the tree by its different colour, and want of hardneſs.

The number of obſervations which Mr. Reaumur made of the blea of trees in different parts of France, all ſhewed him the falſe blea under the ſame number of annual circles of the after-growth of the tree; and theſe being counted, proved juſt as many as the number of years ſince 1709; whence he very juſtly concluded, that all the falſe blea he found throughout the kingdom, was the effect of the ſeverity of this one hard winter. And it is very evident, that this falſe blea is that part of the tree, which in the year 1709 was the true and natural blea, and which the ſeverity of the *frofts* of that winter prevented from ever becoming ſound and ſolid wood, but left it to become more weak and defective for a ſucceſſion of years; during which the ſeveral annual circles of ſupervening blea all became ſound and perfect wood in their natural courſe.

It appears very plain, that the blea muſt be that part of the wood which ſuffers moſt, becauſe it is the outer wood of all, and itſelf makes a covering for the inner part: and add to this, that it is of itſelf of a much leſs compact texture, and contains more juices for the *froſt* to act upon.

Another accident attending trees from very ſevere *frofts* is, that they are ſometimes ſplit by them according to the direction of their fibres, and this often with a very loud crack.

It is not uncommon in large foreſts to meet with trees that have been thus ſplit, and which having outlived the winter that occaſioned it, are found to have a long rib marking the place where the crack was, and forming a ſort of cicatrix or ſcar over the wound. This cicatrix or rib is however only ſuperficial, and wherever it is, the crack is ſtill found remaining under it in the tree; for though the bark and blea can in this manner conſolidate and form a covering for a wound, the fibres of the ſolid wood, when once broken or ſeparated, never cloſe again. It is the general opinion of the workmen, that all theſe cracks in timber are the effects of *froſt*; and it is very eaſy to conceive, that it may be natural for *frofts* to effect it, as it is well known that all frozen liquors take up more room, than they did while in a fluid ſtate. See FREEZING. It is not certain, however, that all the cracks in timber are from this cauſe, many of them may have been occaſioned merely by a redundance of ſap.

The opinions of authors about the expoſition of trees to the different quarters, have been very different, and moſt of them grounded on no rational foundation. Many are of opinion that the effects of *froſt* are moſt violently felt on thoſe trees, which are expoſed to the north; and others think, the ſouth, or the weſt, the moſt ſtrongly affected by them. There is no doubt, but the north expoſure is ſubject to the greateſt cold. It does not, however, follow from this, that the injury muſt be always greateſt on the trees expoſed to the north in *frofts*; on the contrary, there are abundant proofs among the preceding obſervations, that it is on the ſouth ſide that trees are generally moſt injured by *frofts*; and it is plain from repeated experiments, that there are particular accidents, under which a more moderate *froſt* may do more injury to vegetables, than the moſt ſevere one which happens to them under more favourable circumſtances.

It is plain from the accounts of the injuries trees received by the *frofts* of 1709, that the greateſt of all were owing to repeated falſe thaws, ſucceeded by repeated new *frofts*. But the *frofts* in the ſpring ſeaſon furniſh abundantly more numerous examples of this truth; and ſome experiments made by Mr. de Buffon, prove inconteſtibly, that it is not the fevereſt cold, or moſt fixed *froſt*, that does the greateſt injury to vegetables.

This is an obſervation directly oppoſite to the common opinion, yet is not the leſs true, nor is it any way diſcordant to reaſon. We find by a number of experiments, that humidity is the thing that makes *froſt* fatal to vegetables, and therefore every thing that can occaſion humidity in them, expoſes them to theſe injuries, and every thing that can prevent or take off an over proportion of humidity in them, every thing that can dry them, though with ever ſo increaſed a cold, muſt prevent or preſerve them from thoſe injuries. Numerous experiments and obſervations tend to prove this. It is well known that vegetables always feel the *froſt* very deſperately in low places where there are fogs. The plants which ſtand by a river ſide, are frequently found deſtroyed by the ſpring and autumnal *frofts*, while thoſe of the ſame ſpecies, which ſtand in a drier place, ſuffer little, or perhaps not at all by them; and the low and wet parts of foreſts are well known to produce worſe wood than the high and drier; and the coppice wood in wet and low parts of common woods, though it puſh out more vigorouſly at firſt than that of other places, yet never comes to ſo good a growth; for the *froſt* of the ſpring killing theſe early top-ſhoots, obliges the lower part of the trees to throw out lateral branches; and the ſame thing happens in a greater or leſſer degree to the coppice wood that grows under cover of larger trees in great foreſts; for here the vapours not being carried off, either by the ſun or wind, ſtagnate and freeze, and in the ſame manner deſtroy the young ſhoots as the fogs of marſhy places. It is a general obſervation alſo, that the *froſt* is never hurtful to the late ſhoots of the vine, or to the flower-buds of trees, except when it follows heavy dews, or a long rainy ſeaſon, and then it never fails to do great miſchief, though it be ever ſo ſlight.

The *froſt* is always obſerved to be more miſchievous in its conſequences on newly cultivated ground, than in other places; and this is becauſe the vapours which continually ariſe from the earth find an eaſier paſſage from thoſe places than from others. Trees alſo which have been newly cut, ſuffer more than others by the ſpring *frofts*, which is owing to their ſhooting out more vigorouſly.

Froſts alſo do more damage on light and ſandy grounds, than on the tougher and firmer ſoils, ſuppoſing both equally dry; and this ſeems partly owing to their being more early in their productions, and partly to their lax texture, ſuffering a greater quantity of vapours to tranſpire.

It alſo has been frequently obſerved, that the ſide-ſhoots of trees are more ſubject to periſh by the ſpring *frofts*, than thoſe from the top; and Mr. Buffon, who examined into this with great accuracy, always found the effects of the ſpring *frofts* much greater near the ground than elſewhere. The ſhoots within a foot of the ground quickly periſhed by them; thoſe which ſtood at two or three feet high, bore them much better; and thoſe at four feet and upwards frequently remained wholly unhurt, while the lower ones were wholly deſtroyed.

Theſe are a ſeries of obſervations, which have proved beyond all doubt, that it is not the hard *frofts* which ſo much hurt plants, as thoſe *frofts*, though leſs ſevere, which happen when they are full of moiſture; and this clearly explains the account of all the great damages done by the ſevere *frofts* being on the ſouth ſide of the trees which are affected by them, though that ſide has been plainly all the while leſs cold than the north. Great damage is alſo done on the weſtern ſides of trees and plantations, when, after a rain with a weſt wind, the wind turns about to the north at ſun-ſet, as is frequently the caſe in ſpring, or when an eaſt wind blows upon a thick fog before ſun-riſing. Mem. Acad. Scien. Par. 1737.

FROST, *hoar, or white* FROST, *Pruina*, is the DEW *frozen*, or congealed, early in cold mornings; chiefly in autumn. *Hoar-froſt*, Mr. Regis obſerves, conſiſts of an aſſemblage of little parcels of ice cryſtals; which are of various figures, according to the different diſpoſition of the vapours, when met, and condenſed, by the cold.

Dew is, in all appearance, the matter of *hoar-froſt*; though many of the Carteſians will have it formed of a cloud; and either congealed in the cloud, and ſo let fall; or ready to be congealed as ſoon as it arrives at the earth.

FROST-*ſplit*, a phraſe uſed by our farmers to expreſs ſuch trees as have large cracks in their trunks and branches, rendering

rendering them unfit for the uſes they would otherwiſe have ſold for, and by that means greatly debaſing their value. It has been pretended by ſome, that theſe rents and cracks in trees were owing to other cauſes; but we have had innumerable inſtances, and theſe well recorded, of the immediate effect of hard *frosts* on the ſtrongeſt trees, ſpoiling them in this manner; and it appears very rational to ſuppoſe all theſe injuries do really come by the ſame means, and are properly called by this term. Vide ſupra, and the Phil. Tranſ. N° 165.

FROTH, a white, light ſubſtance, formed on the ſurface of fluids, by vehement agitation.

Froth conſiſts wholly of little ſpherules, or globules; and, accordingly, may be defined, an aſſemblage of aqueo-aereal bubbles.

FROTH, in the *Manege*, is a moiſt white matter that comes from a horſe's mouth, otherwiſe called foam. A horſe that by champing on his bridle, throws out a great deal of *froth*, is judged to be a horſe of metal and health, and to have a cold freſh mouth.

FROTH-*ſpit*, or *cuckow-ſpit*, a name given to a ſort of white *froth*, or ſpume, very common in the ſpring, and firſt months of the ſummer, on the leaves of certain plants, particularly on thoſe of the common white field lychnis, or catch-fly, thence called by ſome *ſpotling-poppy*. All writers on vegetables have taken notice of this *froth*, though few have underſtood the cauſe or origin of it, till of late. Many imagined it an exhalation from the earth; ſome have eſteemed it, as its name expreſſes, the ſaliva of the cuckow; others, the extravaſated juices of the plant, and ſome a hardened dew. But all theſe are erroneous opinions, and the account of it is, that it owes its origin to a ſmall inſect, called by ſome the flea-graſs-hopper, which applies its anus cloſe to the leaf, and diſcharges upon it a ſmall drop of a white viſcous fluid, containing ſome air in it, and, therefore, ſoon elevated into a bubble. Before this is well formed, it depoſits ſuch another drop, and ſo on, till it is every way overwhelmed with a quantity of theſe bubbles, which form this *froth*. See CICADULA.

FROUNCE, in the *Manege*, a diſeaſe in horſes, when ſmall warts or pimples ariſe in the midſt of the palate, which are very ſoft and ſore, and ſometimes breed in the lips and tongue.

This diſorder is occaſioned many ways; ſometimes by eating wet hay, whereon rats or other vermin have piſſed; by drawing frozen duſt into their mouths among the graſs, &c.

As to the method of treatment, it conſiſts in letting them blood in the two largeſt veins under the tongue, and waſhing the ſores with vinegar and ſalt, or with ale and ſalt, till they bleed.

FROUNCE, in *Falconry*, a diſeaſe incident to hawks, ariſing from moiſt and cold humours falling down to the palate and root of the tongue; by which means they loſe their appetite, and cannot cloſe their clap. Waſhing with alum-water, lemon-juice, &c. is held good for it.

FROWER, an edged tool, uſed to cleave wood into laths.

FROWEY, a term uſed by workmen for timber, which is evenly tempered, and works freely without tearing.

FROZEN, or **FRIGID *zone***. See ZONE.

FROZEN *ocean*. See OCEAN.

FROZEN *waters*. See WATERS.

FRUCTIFEROUS properly denotes any thing that produces fruit; but in a more large and figurative ſenſe, is uſed by lord Bacon, and others, for ſuch experiments in natural philoſophy, as prove advantageous to the experimenter in point of gain or profit.

FRUCTIFICATION *of plants*. *Fructification* is defined by Linnæus to be the temporary part of a vegetable appropriated to generation, terminating the old vegetable, and beginning the new. It conſiſts of the following ſeven parts; viz. the CALYX, COROLLA, STAMENS, PISTILLUM, PERICARPIUM, SEMEN or SEED, and RECEPTACULUM.

The organs of *fructification* in plants are the *pointal*, generally contained in the middle of flowers; and the *threads*, which ſurround it, furniſhed at their extremities with little *heads*; theſe the botaniſts term the firſt the *piſtillum*, the ſecond the *ſtamina*, and the third, or heads of the ſtamina, the *antheræ*, or *apices*. See FLOWER.

The apices contain the *farina fœcundans*, a fine ſubtile matter analogous to the *ſemen maſculinum* in animals; the ſtamina ſerve only for their ſupport, and to convey nutrition to them; and the *piſtillum* is the part deſtined to receive this *farina*, and convey it to the ſeeds.

It is upon theſe principles that the excellent Linnæus has founded his ſyſtem of the vegetable world, and formed his claſſes. This author's work has been received by the learned world in all nations with the reſpect it merits; but has been too generally cenſured among the ſlighter proficients in botanical reſearches, as abſtruſe, difficult, and unintelligible. The viewing of theſe things in a new light, and the neceſſity of making new words to convey new ideas, have indeed given this great attempt ſomething of the face of an abſtruſe piece; but preſuming a few general hints, it may not be difficult to vindicate the author from the heavy charges which have been laid againſt him, and give the Engliſh reader a clear and perfect view of his work.

From the ſtructure and uſe of the *piſtillum*, *ſtamina*, and *apices*, it is eaſy to conceive that the formers muſt be accounted the *female*, and the two latter the *male parts* of flowers. This is the great baſis of his ſyſtem. To expreſs the different combinations of theſe in the different claſſes of plants, by formal deſcriptions to each, had been tedious, and an exceſſive burden to the memory: to avoid this, he has excellently contrived the compriſing that deſcription, or general character, in one word. It is eaſy to conceive there could be no word already in uſe, that could expreſs what had never before been thought of; he was therefore neceſſitated to invent new ones for this purpoſe. He has ventured therefore to form twenty-four ſuch, for his claſſes, which are of that number, and has taken them from that language which all the learned have ever uſed on the ſame occaſion, the Greek; and this with the leaſt oſtentation or ſhew of learning imaginable: in ſhort, to underſtand all theſe, there is no need of knowing more Greek than that ἀνὴρ ſignifies a *man*, or any thing male; and γυνὴ, a *woman*, or *female*; that δυναμις is *power* or *efficacy*; ἀδελφὸς, a *brother*; and thence ἀδελφια, *brotherhoods*, or *communities*; that σὺν is *together*; γενεσις, *generation*, or *origin*; and οἶκος, a *houſe*, or *habitation*; that πολὺς ſignifies *many*; γάμος, *marriage*; and κρυπτὸς, *hidden*, or *concealed*; and that the numbers one, two, three, four, five, ſix, ſeven, eight, nine, ten, twelve, and twenty, or their derivatives, once, twice, &c. are expreſſed by the Greek words, μόνος, δὶς, τρὶς, τετρὰ, πέντε, ἕξ, ἑπτὰ, ὀκτὼ, ἐννέα, δωδεκα, εἴκοσι: theſe needs, I ſay, no more knowledge of Greek than this, to underſtand perfectly the meaning of all the terms this author, to avoid tedious deſcriptions, has uſed as the characters of his claſſes. To begin with certainty and regularity:

He firſt divides the whole vegetable world into ſuch ſpecies as have their flowers viſible and obvious to the eyes, and ſuch as have them inviſible, or at the utmoſt ſcarce diſcernible.

Thoſe which have them viſible, he then divides ag in into ſuch as have the *ſtamina*, *apices*, and *piſtillum*, that is, the male and female parts of *fructification* in the ſame flower: theſe he, for that reaſon, calls *hermaphrodite* flowers.

And ſuch as have the male and female parts of *fructification*, that is the *apices* and *piſtillum*, either in different flowers upon the ſame ſtalk, or upon different plants of the ſame ſpecies: theſe he calls the diſtinct male and female flowers.

Thoſe which have the different organs of *fructification* lodged in the ſame flower, he again divides into ſuch as have the ſtamina in no part growing together, or cohering to one another; and ſuch as have them either growing together or cohering together mutually in ſome part, either with one another, or with the *piſtillum*.

Thoſe which have them in no part cohering either with the *piſtillum*, or with one another; he again ſubdivides into ſuch as obſerve no exact or accurate proportion of length one among another; and ſuch as have ever two of the ſtamina ſhorter than the reſt.

From theſe general diviſions he deſcends to his particular claſſes, of which he eſtabliſhes twenty-four. See the ſeveral claſſes and orders in the Linnæan ſyſtem illuſtrated by figures in *Tables* I. II. III. IV. V. VI. and VII. *of Botany*.

The firſt thirteen are of the plants which have *hermaphrodite* flowers, with the organs of *fructification* diſjunct, no where cohering with one another, and obſerving no exact proportion in length.

The firſt is the *monandria*, containing two orders: the word is derived from the Greek μόνος and ἀνὴρ, one male part, and ſignifies a flower that has only one ſuch. This claſs accordingly comprehends thoſe plants which have an *hermaphrodite* flower, and in it only one ſingle *ſtamen*: of this claſs are the *hilſtem*, *canna*, &c.

The ſecond is the *diandria*, containing three orders; the word, derived from the ſame ἀνὴρ and δὶς, *twice*, and ſignifying a flower that has two male parts, comprehends all thoſe plants which have *hermaphrodite* flowers with two *ſtamina* in each: of this claſs are the *monarda*, *anthoxanthum*, *piper*, &c.

The third is the *triandria*, containing three orders; the word derived from the ſame ἀνὴρ and τρὶς, *thrice*, ſignifies a flower that has three male parts in it, and comprehends thoſe plants which have *hermaphrodite* flowers with three *ſtamina* in each: of this claſs are the *ixora*, *avenna*, *moluco*, &c.

The fourth is the *tetrandria*, containing four orders; the word,

word, derived from the ſame ἀνὴρ and τετρὰς. *four times*, ſignifies a flower that has four male parts, and accordingly comprehends thoſe plants which have *hermaphrodite* flowers, with four *ſtamina* in each: of this claſs are the *dipſacus, hammamelis, potamogeton*, &c.

The fifth is the *pentandria*, containing ſix orders: the word, derived from the ſame πὴρ and ἀνὴρ, *five*, ſignifies a flower with five male parts; and accordingly this claſs comprehends thoſe plants which have *hermaphrodite* flowers with five *ſtamina* in each: of this claſs are the *nerium, anethum, turnera, parnaſſia, croſſula, myoſurus*, &c. The ſixth is the *hexandria*, containing five orders: the word, derived from the ſame ἕξ, ſignifies a flower that has ſix male parts, and accordingly comprehends thoſe plants which have *hermaphrodite* flowers with ſix *ſtamina* in each: theſe *ſtamina*, the author obſerves, are either all equal in length, or alternately one ſhorter than another; the latter belong to the fifteenth claſs: of this claſs are the *amaryllis, eryna, rumex, peltiveria, aliſma*, &c.

The ſeventh is the *heptandria*, containing four orders: the word, derived from the ſame ἕπτὰ and ἀνὴρ, *ſeven*, ſignifies a flower with ſeven male parts, and comprehends thoſe plants which have *hermaphrodite* flowers with ſeven *ſtamina* in the ſame flower with the *piſtillum*: of this claſs are the *æſculus, ſaururus*, &c.

The eighth is the *octandria*, containing four orders: the word, derived from the ſame ὀκτὼ and ἀνὴρ, *eight*, ſignifies a flower with eight male parts, and comprehends thoſe plants which have *hermaphrodite* flowers with eight *ſtamina* in the ſame flower with the *piſtillum*: of this claſs are the *oenothera, galenia polygonum, adoxa*, &c.

The ninth claſs is the *enneandria*, containing three orders: the word, derived from the ſame ἐννέα and ἀνὴρ, *nine*, ſignifies a flower that has nine male parts, and comprehends thoſe plants which have *hermaphrodite* flowers with nine *ſtamina* in each: of this claſs are the *caſſipa, rheum, butomus*, &c.

The tenth claſs is the *decandria*, containing five orders: the word, derived from the ſame δέκα and ἀνὴρ, *ten*, ſignifies a flower which has ten male parts, and comprehends all thoſe plants which have *hermaphrodite* flowers with ten *ſtamina* in each: of this claſs are the *kamia, ſaxifraga, ſtellaria, oxalis, phytolacca*, &c.

The eleventh is the *dodecandria*, containing five orders: the word, derived from the ſame δώδεκα *twelve*, ſignifies a flower which has twelve male parts in it, and comprehends thoſe plants which have *hermaphrodite* flowers with from twelve to nineteen *ſtamina* in the *hermaphrodite* flower: of this claſs are the *oſyris, agrimonia, euphorbia, ſempervivum*, &c.

The twelfth is the *icoſandria*, containing five orders: the word, derived from the ſame εἴκοσι and ἀνὴρ, *twenty*, ſignifies ſtrictly a flower with twenty male parts in it; the author, however, does not underſtand it in that ſtrict ſenſe, but uſing it as frequently do words expreſſing large quantities, as indefinite and in an indeterminate ſenſe, deſines it to mean only a larger number of *ſtamina* than are expreſſed under any other of the diſtinctions; and comprehends under it, in this claſs, all thoſe plants which have *hermaphrodite* flowers and commonly twenty *ſtamina*, often more, in each; thoſe *ſtamina* alſo growing to the inner ſide of the cup of the flower, not to the receptacle of the future ſeeds: of this claſs is the *punica, crataegus, ſorbus, pyrus, rubus*, &c.

The thirteenth is the *polyandria*, containing ſeven orders: the word, derived from the ſame πολὺς and ἀνὴρ, *many*, ſignifies, in an exact ſenſe, no other than what he makes the *icoſandria*, the title of the laſt claſs, expreſs: theſe are, perhaps, the only two words in which his expreſſion is deficient, the name he has given the claſſes not at all importing their particular difference from one another: this, however, he has very accurately done in the character which follows them; and comprehends under this claſs thoſe plants which have *hermaphrodite* flowers with from twenty to a hundred *ſtamina* in each, but which grow in this to the receptacle of the future ſeed, not as in the other claſs to the inner ſide of the cup of the flower: of this claſs are the *ſarracenia, paonia, aconitum, aquilegia, ſtratiotes, ranunculus*, &c.

Theſe are the claſſes this accurate diſtinguiſher has eſtabliſhed among the *hermaphrodite* flowers, whoſe *ſtamina* have no regular proportion of length, in regard to one another. To theſe he next ſubjoins two claſſes of ſuch of them as have ever two of their *ſtamina* ſhorter than the reſt.

The firſt of theſe (the fourteenth claſs of the general order) is of the *didynamia*, containing two orders: the word, derived from δὶς and δύναμις, *power*, or *efficacy*, ſignifies with him ſuch flowers as have two of their male parts of more efficacy than the reſt; and in this claſs he accordingly comprehends all thoſe plants which have *hermaphrodite* flowers with four *ſtamina*, two of which are cloſe together, longer, and of greater efficacy, in the great work of fecundating the ſeeds, than the reſt: of this claſs are the *wolfitis, melianthus*, &c.

The ſecond of theſe (the fifteenth claſs in the general order) is of the *tetradynamia*, containing two orders: the word, derived from τέτρὰς and δύναμις, ſignifies a flower with four of its male parts of more efficacy than the reſt; and in this claſs he comprehends the plants with *hermaphrodite* flowers, having ſix *ſtamina*, four of which are longer than the reſt, the two oppoſite ſhort: of this claſs are the *lunaria, cheiranthus*, &c.

From theſe he proceeds to thoſe *hermaphrodite* flowers whoſe *ſtamina* cohere either mutually along one another, in different manners, or with the *piſtillum* of the flower: thoſe coalitions of the *ſtamina* he calls brotherhoods, or communities, and according to the different ſtate of theſe, and their conjunction with the *piſtillum*, he eſtabliſhes five claſſes of them.

The firſt of theſe (the ſixteenth in the general order) is the *monadelphia*, containing five orders: the word derived from μόνος, *ſingle*, and ἀδελφὸς, *brotherhood*, or *community*, ſignifies with him a flower, whoſe *ſtamina*, by means of the filaments running in among one another, are all formed into one body; and under this claſs he comprehends thoſe plants with *hermaphrodite* flowers, whoſe *ſtamina*, or male parts, are all bound together in one body: of this claſs are the *hermannia, geranium, peſtaceres, akea*, &c.

The ſecond of theſe (the ſeventeenth claſs in the general order) is the *diadelphia*, containing four orders: the word, derived from δὶς and ἀδελφὸς, ſignifies with him a flower whoſe *ſtamina* are, by the conjunction of their filaments, formed into two bodies; and under this claſs he comprehends thoſe plants which have *hermaphrodite* flowers, the *ſtamina* of which are ſo cluſtered together into two bodies: of this are the *fumaria, polygala, lathyrus*, &c.

The third of theſe (the eighteenth in the general order) is the *polyadelphia*, containing three orders: the word, derived from πολὺς and ἀδελφὸς, ſignifies with him a flower whoſe male parts are cluſtered into three or more ſeparate bodies; and in this he comprehends thoſe plants with *hermaphrodite* flowers, whoſe *ſtamina*, by the conjunction of their filaments, are formed into three or more cluſters: of this claſs are the *theobroma, citrus, hypericum*, &c.

The fourth of theſe claſſes (the nineteenth in the general order) is the *ſyngeneſia*, containing ſix orders: the word derived from σὺν, *together*, and γένεσις, *generation, origin*, or *formation*, ſignifies with him ſuch flowers as have their male parts naturally formed into a ſingle regular congeries; and accordingly he comprehends under this claſs ſuch plants as have *hermaphrodite* flowers, the *ſtamina* of which, by the junction of their *apices*, are formed into a ſingle, regular, cylindric body: of this claſs are the *leontodon, xeranthemum, helianthus, calendula, echinops, lobelia*, &c.

The fifth of theſe claſſes (the twentieth in the general order) is the *gynandria*, containing eight orders: the word, derived from γυνὴ, *a woman*, or *female*, and ἀνὴρ, *male*, ſignifies with this author a conjunction of the male and female parts of a flower at their origin; and he accordingly comprehends under this claſs thoſe plants which have *hermaphrodite* flowers, the *ſtamina*, or male parts of which grow to the *piſtillum*, or female part of the flower, and not to the receptacle of the ſeeds: of this claſs are the *orchis, ſiſyrinchium, paſſiflora, ariſtolochia, arum*, &c.

Next after theſe he ranges thoſe plants which have flowers not *hermaphrodite*, but regularly and diſtinctly male and female, as the ſexes in animals are diſpoſed; and after theſe ſuch plants as have flowers irregularly of one, or the other, or ſomething of both ſexes.

Of theſe he eſtabliſhes only three claſſes.

The firſt of theſe (the twenty-firſt claſs in the general order) is the *monoecia*, containing eleven orders: the word, derived from μόνος and οἶκος, *a habitation*, ſignifies with this author ſuch plants as have their diſtinct flowers on the ſame individual; and he comprehends accordingly under it thoſe plants which have the male and female flowers diſtinct in themſelves, but placed on the ſame plant, or the different ſtalks from the ſame root: of this claſs are the *xanichellia, triſteum, urtica, parietarium, juglans, pinus, monandria, andrachne*, &c.

The ſecond of theſe (the twenty-ſecond claſs in the general order) is the *dioecia*, containing fourteen orders: the word, derived from the ſame δὶς and οἶκος, ſignifies with him plants which have their male and female flowers not on the ſame individual; and accordingly comprehends under it ſuch plants as have diſtinct male and female flowers, on different plants of the ſame ſpecies, either of which, the male and female plants, as they are

hence

hence called, might have arisen from the same seed: of this class are the *salix, empetrum, viscum, humulus, tamus, populus, mercurialis, hippophoe, menispermum, cliffortia, juniperus, ruscus, cluta*, &c.

The third of these (the twenty-third in the general method) is the *polygamia*, containing three orders: the word, derived from πολυς, *many*, and γαμος, *marriage*, signifies with this author plants which have a diversity of combinations, and many ways of *fructification*, in the same species; and accordingly he comprehends under this class those plants which have, in the same species, some flowers male, others female, each distinct and perfect in its kind; and others mixed or *hermaphrodite*, with the male and female organs of *fructification* both in each: of this class are the *veratrum, fraxinus, ficus*, &c.

After all these he places those plants whose flowers are either absolutely invisible, or scarce discernible by the eye: of these he makes only one, his twenty-fourth and last class, the *cryptogamia*: the word, derived from κρυπτος, *hidden*, or *concealed*, and γαμος, or *marriage*, signifies a set of plants, in which the *fructification* is concealed; and under this last class he comprehends those plants which either flower, as is generally supposed, within the fruit, or have the organs of their *fructifications* so mingled as to escape our observation: of this class are the *ferns, mosses, flegs*, and *mushrooms*; e. gr. *polypodium, hypnum, fucus*, and *agaricus*.

These are the classes into which this author has regularly and accurately reduced the whole vegetable world; the characters of which are so expressive, and the parts they are founded upon so fixed and invariable in their nature and office, that there seems no reason hereafter to perplex the world with any new system.

As the classes are here all taken from the number, site, and disposition of the male parts of the flower, so the orders which make their subdistinctions are, by this author, deduced from the differences of the female parts or *pistillum*; and as that is single, double, triple, and so on, they are on the same principles named *monogynia, digynia, trigynia*, &c.

It were to be wished indeed, that the characters of the different genera of these classes were as perfect and accurate as the classes themselves: this, however, was more than the work of one man; the author has fixed the general distinction, and led the way, and it is easy now for a much less genius to follow him.

FRUCTISTÆ, in *Botany*. See BOTANY.

FRUGIVOROUS *Birds*, are such as feed on fruits; either wholly or in part.

The *frugivorous*, according to Mr. Willughby, are a species of terrestrial birds, some of which have crooked bills, and claws, yet are of gentler nature, and not rapacious. Such are the parrot kind: which, though sometimes carnivorous, yet feed likewise on fruit.

FRUIT, in its general sense, includes whatever the earth produces for the nourishment and support of animals; as herbs, grain, pulse, hay, corn, flax, and every thing expressed by the Latins under the name *fruges*.

In the civil law, they distinguish three kinds of *fruits*.

FRUITS, *natural*, which the earth produces spontaneously, and without any culture; as those of trees.

FRUITS *of industry*, which, though natural, require some culture to perfect them. And

FRUITS, *civil*, which are only *fruits* in the eye of law; as rents, salaries, wages, &c.

In the canon law, *fruits* include every thing whereof the revenue of a benefice consists; as glebe-land, tythes, rents, offerings, mills, &c.

FRUIT, in *Natural History*, denotes the last production of a tree, or plant, for the propagation, or multiplication, of its kind; in which sense *fruit* includes all kinds of seeds, with their furniture, &c.

FRUIT, in *Botany*, is properly that part of a plant wherein the seed is contained; called by the Latins *fructus*, and by the Greeks καρπος.

The *fruit* in the Linnæan system is one of the parts of fructification, and is distinguished into three parts, viz. the PERICARPIUM, SEED, and receptacle, or RECEPTACULUM *seminum*.

FRUITS are sometimes dry; and sometimes soft and fleshy.

FRUIT also implies an assemblage of seeds in a head; as in a ranunculus, &c. and in the general, all kinds of seeds, or grains, whether naked, or inclosed in a cover, capsule, or pod; and whether bony, fleshy, skinny, membranous, or the like. The *fruit* is the product, or result, of the flower; or that for whose production, nutrition, &c. the flower is intended. The structure and parts of different *fruits* are somewhat different; but, in all the species, the essential parts of the *fruit* appear to be only continuations, or expansions, of those observed in the other parts of the tree.

Dr. Beal suggests some very good reasons for a direct communication between the remotest part of the tree, and the *fruit*; so that the same fibres, or flamina, which constitute the root, trunk, and boughs, are extended into the *fruit* itself.

Thus, cutting open an apple transversely, it will be found to consist of four parts; viz. 1. a skin, or *cortex*, which is only a production of the skin, or outer bark, of the tree. 2. A *parenchyma*, or pulp; which is an expansion, and intumescence of the inner bark of the tree. 3. Fibres, or ramifications, of the woody part of the tree, dispersed throughout the *parenchyma*.

Of these last, authors generally reckon fifteen principal branches; ten whereof penetrate the parenchyma, and incline to the basis of the flower; the other five ascend more perpendicularly from the pedicle, or stalk, and meet with the former at the base of the flower; to these branches are fastened the capsulæ, or coats, of the kernels.

These branches, being at first extended through the parenchyma to the flower, furnish the necessary matter for the vegetation thereof: but, the *fruit* increasing, intercepts the aliment; and thus the flower is starved, and falls off.

4. The core, which is the produce of the pith, or medulla, of the plant, indurated and strengthened by twigs of the wood and fibres, insculated therewith: it serves to furnish a cell, or lodge, for the kernels; filtrates the juice of the parenchyma; and conveys it, thus prepared, to the kernel.

In a pear we distinguish five parts; viz. the skin, parenchyma, ramification, stone, and acetarium.

The three first parts are common to the apple. The stone, observed chiefly in shook pears, is a congeries of hard corpuscles, dispersed throughout the whole parenchyma; but in the greatest plenty, and closest together, about the centre, or acetarium: it is formed of the harder, or calculous parts, of the nutritious juice of the parenchyma, extravasated in masses. The acetarium is a substance of a tart, acid taste, of a globular figure, inclosed in an assemblage of several of the stony parts above mentioned.

In the plum, cherry, &c. there are four parts; viz. a coat, parenchyma, ramification, and stone or nucleus. The stone consists of two very different parts; the inner, called the kernel, is soft, tender, and light; being derived from the pith, or medulla, of the tree, by seminal branches, which penetrate the base of the stone; the external or harder part, called the shell, is a concretion of the stony, or calculous parts of the nutritious juice, like the stone in pears; and, like that, it contains a soft parenchymous matter within it.

The nut, analogous to which is the acorn, consists of a shell, cortex, and medulla. The shell consists of a coat, and parenchyma, derived from the bark, and wood, of the tree. The cortex consists of an inner, and outer part; the first is a duplicature of the inner tunic of the shell; the second is a mossy substance, derived from the same source as the parenchyma of the shell. But whether the medulla or pulp of the kernel arise from the pith of the tree, or the cortical part of the fruit, is not yet agreed.

Lastly, berries, as grapes, &c. besides the three general parts, viz. coat, parenchyma, and ramification, contain grains of a stony nature, which do the office of seeds.

As to the use of *fruits*, beside the pleasure and advantage they afford men, &c. they are of service in guarding, preserving, and feeding the seed inclosed: in filtrating the coarser, more earthy, and stony parts of the nutritious juice of the plant, and retaining them to themselves: and sending none to the seed but the purest, most elaborated, and spirituous parts, for the support and growth of the tender, delicate embryo, or plantule, contained therein.

So that the *fruit* does the same office to the seed, that the leaves of the flower do to the *fruit*.

The use of *fruits* with us might, under proper regulations, be rendered much more extensive than it is. Many *fruits* which do hurt when eaten raw, would make wines equal in flavour to many of those now obtained at great prices from abroad; and lands which will not bear corn, yet would bear trees and shrubs producing such *fruits*; and the consequence of this method of culture would be, that much ground, at present lying waste, would be occupied, and great employment found for the numerous poor of some of our counties, where the quantities of waste land are proportionably so great, that there is no employment for the people of one half of the county. Cherries properly managed make an excellent wine, and that in very large quantities; and plums also make a very agreeable kind; but that it has an austereness, which must be taken off by mixing a little sugar with it when in the glass, not before it is drawn off.

A coarse plum, somewhat larger than a damson, is the best

beſt kind for this wine. There is a ſort of plum that grows wild in ſome of our hedges. It will ſucceed on any ground, the pooreſt that can be imagined, and it produces a great abundance of *fruit*. The wine that is made from it is of a very conſiderable ſtrength, and affords a pleaſant brandy by diſtillation in conſiderable quantities. Our common garden currants afford a very agreeable wine; and our gooſeberries are not ſecond to any thing. All theſe produce *fruit* in great abundance; and the planting and taking care of them is very cheap, and the operation very eaſy. The common way of making theſe wines yields very good ones; but when the art of the experienced Vigneron is employed in it, the liquors will prove much better. Phil. Tranſ. N° 124.

Fruits are diſtinguiſhed, by gardeners, into *ſtone-fruit*, and *kernel-fruit*; *ſummer-fruit*, and *winter-fruit*; *wall-fruit*, and *eſpalier-fruit*, &c.

M. Quintinie obſerves, that cold, heavy, moiſt lands, produce the faireſt and largeſt *fruit*; but the hotter, drier, and lighter, the more delicious and rich-taſted.

FRUITS, *colours from*. The red juices of *fruits*, as of currants, mulberries, elder-berries, morello, and black cherries, when inſpiſſated and dried, may be again diſſolved in water, to which they give nearly the ſame red colour as they do when freſh. Rectified ſpirit extracts the tinging particles, and acquires a brighter colour than the watery ſolution; becauſe much of the mucilage is left undiſſolved by the former. The red ſolutions, and the juices, are ſometimes made dull, and ſometimes more florid, by acids, and are generally rendered purpliſh by alkalies. The colours of theſe juices are generally periſhable. They reſiſt the power of fermentation, but quickly decay, when the juice is ſpread thinly on any ſubſtance, and dried in open air. The bright lively reds are ſooneſt changed; the dark, dull, red ſtain of the black cherry is conſiderably durable. The bright red *fruit* of the *opuntia*, or prickly pear, is an exception to the above rule; as it gives, according to Labat, a beautiful red dye. The ripe berries of BUCKTHORN ſtain paper of a green colour; from theſe is prepared the ſubſtance called SAP-*green*; which is a pigment ſufficiently durable, ſoluble in water, but not miſcible with oil. The berries, when green, yield a yellow, and, when over-ripe, a purple pigment. Woollen cloth, prepared with alum and tartar, receives, on being boiled with the berries, a periſhable yellow dye. Neumann's Chem. with Dr. Lewis's Notes. p. 433. See AVIGNON *Berry*, ANNOTTO, or ROUCOU, and TURNESOL.

FRUITS, *preſervation of*. See *Preſervation of* FLOWERS, and PRESERVATION *of Vegetables*.

Fruits intended for long keeping ſhould be gathered before they are fully ripe, and in a fair day towards noon.

For the early ripening of *fruit*, ſee FORCING and RIPENING.

FRUIT, *bread*. See BREAD.

FRUITS, with regard to commerce, are diſtinguiſhed into *recent* or *freſh*, and *dry*.

FRUITS, *recent*, or freſh ſold juſt as they are gathered from the tree, without any farther preparation. As are moſt of the productions of our gardens and orchards, ſold by the fruiterers.

FRUITS, *dry*, are thoſe dried in the ſun, or by the fire, with other ingredients ſometimes added to them to make them keep; imported chiefly from beyond ſea, and ſold by the grocers.

Such are raiſins, currants, figs, capers, olives, cloves, nutmegs, pepper, and other ſpices; which ſee under their reſpective articles.

Under the denomination of *dry fruits* are alſo frequently included apples, pears, almonds, filberds, &c.

FRUITS, *polyſpermous*. See POLYSPERMOUS.

FRUITS *current* for coins. See COIN.

FRUITS, *firſt*. See FIRST *fruit*, ANNATES, and PRIMITIÆ.

FRUIT-*flies*, a name given by gardeners, and others, to a ſort of ſmall black *flies*, found in vaſt numbers among *fruit*-trees, in the ſpring-ſeaſon, and ſuppoſed to do great injury to them.

Theſe are a ſpecies of ſmall black fly. Mr. Leewenhoek preſerved ſome of them for his microſcopical obſervations. He found that they did not live longer than a day or two, but that the females in this time uſually laid a great number of longiſh eggs. The gardeners who ſuppoſe that theſe flies wound the leaves of the trees, are miſtaken: it is true that they feed on their juices, but they have no weapons with which to extract this themſelves; they feed on ſuch as is naturally extravaſated, and when there is not enough of this for their purpoſe, they haunt thoſe places where the PUCERONS reſort, and feed on the juices which theſe little creatures extravaſate by means of the holes they bore in the leaves with their trunks. Theſe pucerons are a ſmall ſort of inſect very common on our *fruit*-trees, and other plants and trees; they are of a greeniſh colour, and are commonly called tree-lice. Phil. Tranſ. N° 262.

FRUIT-*ſtones*. The miſchiefs ariſing from the bad cuſtom of many people ſwallowing the ſtones of plums and other *fruit* are very great. The Philoſophical Tranſactions give us an account of a woman who ſuffered violent pains in her bowels for thirty years, returning once in a month or leſs. At length a ſtrong purge being given her, the occaſion of all theſe complaints was driven down from her bowels to the anus, where it gave a ſenſation of ſtoppage and diſtenſion, and produced a continual deſire of going to ſtool, but without voiding any thing. On the aſſiſtance of a careful hand in this caſe, there was taken out with a forceps an oblong ball of an oval figure, of about ten drams weight, and meaſuring five inches in circumference; this had cauſed all the violent fits of pain ſhe had been ſo many years afflicted with, and after the taking it out ſhe became perfectly well. The ball extracted looked like a ſtone, and felt very hard, but it ſwam in water; on cutting it through with a knife, there was found in the centre of it a plum-ſtone, round which ſeveral coats of this tough and hard matter, reſembling a ſtone, had gathered. Another inſtance given in the ſame papers is of a man, who dying of an incurable colic, which had tormented him many years, and baffled the effects of medicines, was opened after death; and in his bowels was found the cauſe of his diſtemper, which was a ball of the like nature with that juſt mentioned, but ſomething larger, being ſix inches in circumference when meaſured, and weighing an ounce and half; in the centre of this, as of the other, there was found the ſtone of a common plum, and the coats were of the ſame matter with thoſe of the former. Theſe and ſeveral other inſtances mentioned in the ſame place, ſufficiently ſhew the folly of that common opinion, that the ſtones of *fruits* are wholeſome.

For though by nature the guts are ſo defended by their proper mucus, that people very ſeldom ſuffer by things of this kind, yet if we conſider the various circumvolutions of the guts, their valves and cells, and at the ſame time conſider the hair of the ſkins of animals we feed on, the wool or down on herbs and *fruits*, and the fibres, veſſels, and nerves of plants, which are not altered by the ſtomach, it will appear a wonder that inſtances of this ſort of miſchief are not much more frequent. Cherry ſtones, ſwallowed in great quantities, have occaſioned the death of many people, and there have been inſtances even of the ſeeds of ſtrawberries, and kernels of nuts, collected into a lump in the guts, and cauſing violent diſorders, which could never be cured till they were carried off. Philoſ. Tranſ. N° 282. p. 1282.

FRUIT-*trees* are diſtinguiſhed, like the *fruits* they bear, into wall *fruit*-trees, ſtandard *fruit*-trees, &c.

With regard to *fruit*-trees, Monſ. Quintinie obſerves,

1. That the cutting and trimming of young trees hinders them from quick bearing; though it contributes both to the beauty of the tree, and to the richneſs and flavour of the fruit.

2. That kernel *fruit*-trees come later to bear than ſtone *fruit*-trees; the term required by the firſt, before they arrive at a fit age for bearing, being, one with another, about four or five years; but, when they do begin, they bear in greater plenty than ſtone-*fruit*.

3. That ſtone-*fruits*, figs, and grapes, commonly bear conſiderably in three or four years; and bear full crops the fifth and ſixth years; and hold it for many years, if well ordered.

4. That *fruits*, in the ſame neighbourhood, will ripen a fortnight ſooner in ſome grounds, than in others of a different temperature.

5. That in the ſame country, hot or cold ſummers ſet conſiderably forwards or put backwards, the ſame *fruit*.

6. That the *fruits* of wall-trees generally ripen before thoſe on ſtandards; and thoſe on ſtandards before thoſe on dwarfs.

7. That the *fruit* of all wall-trees, planted in the ſouth and eaſt quarters, commonly ripen about the ſame time; only thoſe in the ſouth rather earlier than thoſe in the eaſt; thoſe in the weſt are later by eight or ten days; and thoſe in the north by fifteen or twenty.

For the planting, pruning, ingrafting, &c. of *fruit*-trees, ſee PLANTING, TRANSPLANTING, PRUNING, and ENGRAFTING. See alſo ORCHARD, GARDEN, and NURSERY.

Monſ. de Reſſons, in the Memoires de l'Academie Royale des Sciences, ann. 1716, gives us a method of grafting ſtone *fruit*-trees without loſing of time; ſo that a tree which bore bad *fruit* the preceding year, ſhall bear the choiceſt *fruit* the year following.

It frequently happens that perſons are deceived in their *fruit*-trees, eſpecially thoſe bought of the nurſery-men;

and it is an unpleasing thing, after having waited three years for *fruit*, to find it bad at last, and to be obliged to graft the tree again, and wait four years more for the second hopes. In effect, in the common methods of grafting, they know nothing better than to cut off the head of a tree, and make it put forth new wood to graft in: this neceſſarily makes a long delay, which Monſ. Reſſons ſhews how to abridge.

Upon conſidering the union of the ſap in grafts, that author was led to think, that all the office the bark has in grafting, is to receive the ſcutcheon; ſo that if the bark be not quite hard, dry, and inflexible, and incapable of yielding without cracking or burſting, it ſhould ſeem indifferent, whether one grafted on new wood, or old, the ſap paſſing equally into both: which reaſoning had the good fortune to be verified by a number of experiments made with that view.

We are at liberty, then, to graft almoſt at any age, and in any wood. Accordingly, a peach tree of a worſe kind or quality may be grafted from another of the beſt, in autumn, in the height of its *fruit* and ſap, without cutting off any branches; the graft ſoon cements to the tree by the union of the ſaps, without ſhooting at all: ſo that, cutting off the branches above the graft the ſpring following, the ſame graft inſerted the preceding autumn will ſhoot vigorouſly; and, being on a wood of the ſame kind, the *fruit* thenceforth produced will be much the larger and finer. But this is not the great point: for the tree thus engrafted will not bear till the third year, and we want *fruit* the firſt.

In order to this it is to be obſerved, that there are three kinds of branches: wood-branches, growing immediately from the ſtem or ſtock of the tree; *fruit*-branches; and branches half of the wood, half of the *fruit* kind, being ſuch as, ariſing from the largeſt wood-branches, preſerve the character thereof, but which, in two years time, will produce *fruit*-branches. Now, this intermediate kind of branches ſhould be choſen for ſcutcheons or grafts. They are eaſily known by being bigger than the *fruit*-branches, and leſs than the wood-branches: they have each of them two, three, four, or even five leaves to each eye; and the eyes are farther diſtant from each other than thoſe of the *fruit*-branches, but cloſer than thoſe of the wood-branches. It muſt be added, that the eyes on ſuch branch are three; one intended for a wood-branch, being ſituate between the two leaves, and advancing farther than the other two, which are intended for *fruit*, and are placed without-ſide the leaves.

Theſe laſt are the preciſe ſubjects to be choſen for the purpoſe of grafting. Twelve of theſe ſcutcheons, more or leſs, according to the ſtrength of the tree to be grafted on, being duly applied, we may depend on a crop of good *fruit* the very next year, on the ſame tree which the laſt year produced the worſt.

There is, in the Philoſophical Tranſactions, a method of making *fruits* and flowers grow in winter inſtead of ſummer, without the common way of doing it by heat. This method is to take up the trees with their roots in the ſpring-ſeaſon, juſt as they begin to ſhoot out their buds; let them be placed upright in a cellar, and ſtand there till the end of September following; then fit veſſels to them, and place the roots in them, covering them in a proper manner with earth, and bring them up into a common ſtove; water them at times with a ſolution of the ſigneſs of a walnut of crude ſal ammoniac in a quart of rain-water, and they will make their natural progreſs as in ſummer, and in the months of February or March following the *fruit* will be full ripe, and as well taſted as if it had grown on them in the common way, and ripened at its natural ſeaſon. Phil. Tranſ. N° 282. p. 44.

The ſuperfluous ſhoots from theſe trees muſt be pruned off at ſuch times of the year, when the trees are full of juice, and furniſhed for a farther ſupply; and by this means there will be no marks of the wounds, they will cloſe up ſo perfectly. The manner of producing pyramidal trees by ingrafting, is not only applicable to *fruit*-trees, but has been tried on oaks, limes, and roſes, with the ſame ſucceſs. Vide infra.

Lauremberginus tells us of a peculiar way of managing *fruit*-trees for ready ſervice and beauty, by means of which they will bear *fruit* the firſt year. The method is this: draw a branch of a *fruit*-tree through a pot of earth, and prick it full of holes with a knife, ſo far as it is to ſtand in the pot: let it be well watered for the firſt ſeven or eight days, to make it ſhoot out a great quantity of roots; in the March following cut off the branch from the tree, and let it depend wholly on itſelf for nouriſhment; break the pot away, and place the clump of earth with the young tree in it in the place where it is intended to ſtand. The author aſſures us it will partake ſo much of the nature of the ſtock, as to bear *fruit* the firſt year. Philoſ. Tranſ. N°[illegible]3.

An anonymous author has given us, in a treatiſe publiſhed at Hamburgh, under the title Amœnitates Hortenſes Novæ, a new method of graſting trees, ſo as to have very beautiful pyramids of *fruit* on them, which will exceed both in quantity, beauty, and flavour, all that can be otherwiſe produced. This, he ſays, he had long experienced, and the method he gives of doing it is this: the trees are to be tranſplanted in autumn, and all the branches cut off; early in the following ſummer the young ſhoots are to be pulled off, and the buds are then to be ingrafted into them in an inverted direction; this, he ſays, adds not only to the beauty of the pyramid, but makes the branches alſo more fruitful. Theſe are to be cloſely connected to the trunk, and to be faſtened in with the common ligature; they are to be placed circularly round the tree, three buds in each circle, and theſe circles at ſix inches diſtance from one another. The old trees may be ingrafted in this manner, the ſucceſs having been found very good in thoſe of twenty years ſtanding; but the moſt eligible trees are thoſe which are young, vigorous, and full of juice, and have not more thickneſs than a finger or two. When theſe young trees are tranſplanted, they muſt be fenced round with pales, to defend them from the violence of the winds; and there muſt be no dung put to them till they are thoroughly rooted, for fear of rotting them before the fibres ſtrike. The buds ingrafted muſt be ſmall, that the wounds made in the bark to receive them, not being too large, may heal the ſooner; and if any of the buds do not ſucceed, which will be found in a few night, there muſt be others put in their place. The wound made to receive theſe buds, muſt be a ſtraight cut, parallel to the horizon, and the piece of bark taken out muſt be downward, that the rain may not get in at the wound. In the autumn of the ſame year, this will be a green and flouriſhing pyramid, and the next ſummer it will flower, and ripen its *fruit* in autumn. Act. Erud. ann. 1710.

The Peterſburg Academy furniſhes us with two very ſingular inſtances of *fruits* growing in an unnatural manner; the one of thoſe in the fig-tree, the other in the apple-tree. In both thoſe caſes, the *fruit*, inſtead of its common ſituation, was placed upon the trunk of the tree, with no branch or leaf near it, but only a ſhort pedicle for its ſupport. The inſtance of the fig-tree afforded three figs in a cluſter, the middle one of which withered, but the other two grew to their proper ſize, and were like the reſt of the figs on the ſame tree. The other inſtance of the apple-tree afforded only one ſingle *fruit*; but there was in it ſomething very ſtrange, or that appeared ſo, however, at firſt ſight; for the apples produced on the branches of the tree were of one kind, and this of another. The tree had been grafted, and all the *fruit* of the branches grew from the graft; this ſingle one, which ſtood upon the trunk of the tree below the graft, was of the ſpecies produced by the ſtock. This had doubtleſs been preceded by a flower, though unobſerved, and it could only be, as it appeared, of the nature of the genuine *fruit* of the ſtock. All gardeners know, that the ſtock ſuffers no change from the graft; in both theſe caſes there was probably the rudiment of a branch where the ſingle *fruit* appeared, and every other part of it, except the bud of the *fruit* alone, had periſhed, while that arrived at its deſtined ſize and maturity. We have alſo an account in the Philoſophical Tranſactions, N° 385, of an apple-tree bearing a conſiderable quantity of *fruit* for many years together without bloſſoming.

FRUITERY, a place for the laying up and keeping of FRUIT. See GRANARY.

The *fruitery* ſhould be inacceſſible to any thing of moiſture, or even froſt.

FRUITFULNESS, the quality of bearing plenty of fruit, called alſo FERTILITY, and FECUNDITY.

FRUMENTACEOUS *plants* are thoſe which produce granulated or knotted ſtalks, with reed-like leaves; and whoſe ſeed growing in ſpikes or *tubæ*, is uſeful to make pulſe, or bread.

The word is formed from *frumentum*, a general name comprehending all ſorts of corn, or grain, for bread. Hence the Italians, who follow the Latins, uſe *grano* and *frumento* for the ſame.

Wheat, barley, rye, millet, &c. are *frumentaceous* plants. Some authors uſe *frumentaceous* in a narrower ſenſe, reſtraining it to plants which bear a conformity to wheat, either in reſpect of their fruits, leaves, ears, or the like. But this ſeems founded on a miſtaken notion of *frumentum*, as if it denoted only *wheat*, which is rather the ſenſe of the word *triticum*.

FRUMENTARII, in *Antiquity*, a kind of ſoldiers, or archers, under the Weſtern empire.

St. Cyprian relates, in one of his letters, that ſome of theſe *frumentarii* were ſent to take him.

The firſt time we read of *frumentarii*, as officers, is in the

the time of the emperor Adrian. Spartian, in his life of that prince, aſſures us, that he made uſe of them to inform himſelf of what paſſed.

Before this time, the name *frumentarius* was only given to the corn-merchants, or meaſurers of corn.

Theſe *frumentarii* did not make any particular corps, diſtinct from the other forces, but there was a certain number of them in each legion, as, among us, there is a certain number of grenadiers in each battalion. Accordingly, in ancient inſcriptions, we meet with *frumentarii* of this or that legion. It is ſuppoſed they were originally a number of young perſons, diſpoſed by Auguſtus throughout the provinces, particularly on all the grand roads to advertiſe the emperor, with all expedition, of every thing that happened.

In order to this they had a kind of intendance of all the carriages, and on this account came to be employed for the conveyance of corn, *frumentum*, to the armies; whence their appellation.

Afterwards they were incorporated into the troops themſelves, where they ſtill retain their ancient name.

Their principal office was the giving intelligence, in which they agreed with thoſe called *curioſi*, with whom they were frequently joined. See CURIOSUS.

FRUMENTATION, *frumentatio*, among the *Romans*, a largeſs of corn beſtowed on the people. This practice of giving corn to the people, was a very ancient cuſtom among the Romans, and frequently uſed to ſooth the turbulent humour of the populace.

At firſt the number of thoſe to whom this largeſs was given, was indeterminate, till Auguſtus fixed it at two hundred thouſand.

FRUMENTUM *Saracenicum*, in *Botany*, a name by which ſome authors expreſs the fagopyrum, or *buck-wheat*.

FRUMENTUM *Indicum*, *Indian corn*, a name given by our American planters to MAIZE.

FRUMENTY, popularly FURMETY, a kind of pottage, the baſis whereof is wheat, boiled up with milk, ſugar, and ſometimes ſpice.

Pliny tells us, that in his time they mixed chalk among it. Galen deſcribes it as a very nutritious food made of corn, or pulſe, boiled with water, wine, and oil.

The Latins called it *alica*, which Feſtus derives *ab alendo*, as being very nouriſhing. But then it muſt be obſerved, they made it of any kind of corn.

Ours being reſtrained to wheat, we have given its denomination accordingly, from *frumentum*. An emuliion, wherein wheat was an ingredient, would be a kind of *frumenty*.

FRUMGYLD, in *our old Writers*, is the firſt payment made to the kindred of a perſon ſlain, towards the recompence of his murder.

FRUMSTOL, in *our old Writers*, the chief ſeat or manſion-houſe, which is called by ſome the *homeſtal*. Leg. Inæ, cap. 38.

FRUSO, in *Zoology*, a name given by ſome to the *cocothrauſtes criſtata Indica*, commonly called the *Virginia* NIGHTINGALE.

FRUSSURA, in *our old Writers*, a breaking down; alſo a ploughing or breaking up. *Fruſſura domorum* is houſe-breaking; and *fruſſura terræ*, new broke land.

The word comes from the French, *freiſſure*, a *bruiſe*; and that from the verb *freiſſer*, *to bruiſe* or *break*.

FRUSH, or FROG, in the *Manege*, is a ſort of tender horn which ariſes in the middle of the ſole, and at ſome diſtance from the toe of a horſe; it divides into two branches, running towards the heel, in form of a fork.

FRUSTUM, in *Mathematics*, a piece cut off or ſeparated from a body.

FRUSTUM of a pyramid, or cone, is a part or piece thereof cut off, uſually by a plane parallel to the baſe.

All round and ſquare timber that grows tapering, may be conceived as the *fruſtum* of a cone, or pyramid: to find the quantity whereof, take the following theorem, which in the main is Mr. Oughtred's. Given, B (*Tab. Survey. fig.* 10.) the ſide of the greater baſe, *b* the leſſer baſe's ſide, A the height of the *fruſtum*: though, below, we ſuppoſe B and *b* to repreſent the areas of the two baſes. Whole height *a*+A=H.

Firſt, to find *a*, ſay, as B—*b* : *b* :: A : $\frac{b}{B-b}A$ or $\frac{bA}{a}$.

Now BH=3 times the whole pyramid, becauſe any priſm is three times a pyramid of the ſame baſe and height within, by 7 and 10 Euclid, and *ba*=3 times the upper pyramid.

Wherefore $\frac{BH-ba}{3}$ equal to the *fruſtum* of the pyramid required; which theorem in words is this:

Multiply the lower baſe by the whole height, and from the product ſubtract the upper baſe multiplied by the height of the top-piece wanting, and then one third of the remainder ſhall give the *fruſtum*.

And in the ſame way you may proceed for the *fruſtum* of a cone; only it will be more difficult to find the circular baſes. See CONE.

FRUSTUM *of a ſphere*. See SEGMENT.

We have a general theorem in Mr. Maclaurin's Treatiſe of Fluxions, concerning the *fruſtum* of a ſphere, cone, ſpheroid, or conoid, terminated by parallel planes, when compared with a cylinder of the ſame altitude, on a baſe equal to the middle ſection of the *fruſtum* made by a parallel plane. The difference between the *fruſtum* and the cylinder is always the ſame in different parts of the ſame, or of ſimilar ſolids, when the inclination of the planes to the axis, and the altitude of the *fruſtum*, are given.

In the parabolic conoid this difference vaniſhes, the *fruſtum* being always equal to a cylinder of the ſame height, upon the ſection of the conoid that biſects the altitude of the *fruſtum*, and is parallel to its baſes.

In a ſphere the *fruſtum* is always leſs than the cylinder by one fourth part of a right angled cone, of the ſame height with the *fruſtum*, or by one half of a ſphere of a diameter equal to that height; and this difference is always the ſame in all ſpheres, when the altitude of the *fruſtum* is given.

In the cone, the *fruſtum* always exceeds the cylinder by one fourth part of the content of a ſimilar cone that has the ſame height with the *fruſtum*.

In the hyperbolic conoid this exceſs is the ſame as in the cone generated by a triangle *o c e*, (*Tab.* II. *Geometry*, *fig.* 44.) formed by the axis *o c*, the aſymptote *o e*, and a perpendicular *c e*, the altitude of the *fruſtum* and the inclination of the axis to their baſes being the ſame in both.

In the ſpheroid (*fig.* 45.) the cylinder exceeds the *fruſtum* ; and the difference between them is the ſame as in the cone C D *d*, the plane D *d*, or B *b*, being ſuppoſed parallel to thoſe which terminate the *fruſtum*. In different inclinations of thoſe planes, when the altitude of the *fruſtum* is given, that difference is reciprocally as the cube of the diameter B *b*, which is the conjugate of C A, the axis of the *fruſtum*. But if the altitude of the *fruſtum* be alſo varied ſo as to be reciprocally proportional to the diameter B *b*, then the difference between the *fruſtum* and cylinder will be always of the ſame magnitude in the ſame ſpheroid or conoid.

When the inclination of the axis of the ſolid to the planes that terminate the *fruſtum* is given, the difference between the *fruſtum* and cylinder, in the ſame, or in ſimilar bodies, is as the cube of their common altitude. Maclaurin's Fluxions, Introd. p. 24, 25.

Theſe propoſitions concerning *fruſtums* are of uſe in GAUGING.

FRUTEX. See SHRUB.

FRUTEX *Æthiopicus*, in *Botany*, a name given to the ſilver PINE-*tree*.

FRUTEX *Africanus*, in *Botany*, a name given to a ſpecies of trees brought from the Cape of Good Hope; a deſcription of which ſee under *Sparge-leaved* PINE.

FRUTICOSE *ſtalks of plants* are thoſe of a hard, woody ſubſtance.

FRY, in *Ichthyology*, ſignifies the ſpawn, or rather the young of fiſh. See FISH.

FRYTH, or FRITH, is explained, by ſir Edward Coke, as a plain between two woods, or a lawn.

Camden tells it for an arm of the ſea, or a ſtreight between two lands, from *fretum*.

Frith, from the Saxon *frid*, *peace*, is alſo uſed for a wood; becauſe the Engliſh Saxons held woods to be ſacred, and uſed them as ſanctuaries.

FUAGE, or FOCAGE, a tax or impoſition laid on hearths or chimneys, i. e. on fire-places, or families, from which was probably derived the *hearth-ſilver*, and *chimney-money*. This duty was repealed by 1 William and Mary, ſeſſ. 1. cap. 10.

Edward the Black Prince, having Aquitain granted him, laid an impoſition of *fuage*, or *focage*, upon the ſubjects of that dukedom, viz. one ſhilling for every fire-place. After his example, Charles V. of France, laid a tax of a franc for each fire-place, for one year only. His ſucceſſor Charles VI. augmented it under the ſame name. Charles VII. rendered it perpetual, and called it *taille*. By an ordonnance of Humbert II. dauphin of Viennois, the impoſition of *focage*, or *fouage*, was then laid per feu, i. e. per fire, or family, *ſin per lares focum habentes*. In Latin it was called *focagium*, q. d. *pro ſtoguli focis*. Sometimes it was alſo called *fourvage*, on account of the oven or furnace: in Greek καπνικὸν or καπνὸς, *fumus*, *ſmoke*. In Will. Tyr. De Bello Sacro, it is called *fougium*: for it was impoſed by the kings of Jeruſalem. The counts and other lords, likewiſe impoſed it on the feudataries,

feudataries, or vaſſals. Zonaras aſſures us, that the general Nicephorus firſt eſtabliſhed it among the Greeks. See CHIMNEY-*money*.

FUCA, in *Ichthyology*, a name given by Gaza, and ſome other writers, to the fiſh called phycis, by Ariſtotle, Ælian, and other writers; and *tinca marina*, by Salvian and Rondeletius. It is a fiſh nearly allied to the genus of the blenni.

FUCHSIA, in *Botany*, the name of a genus of plants of the *octandria monogynia* claſs; ſo called by Plumier, in memory of the famous Botaniſt Fuchſius, Plum. Nov. Gen. 14. the characters of which are theſe: the flower hath one petal with a cloſed tube, ſlightly cut into eight parts at the brim; and hath four ſtamina the length of the tube. An oval germen is ſituated under the flower, which afterwards becomes a ſucculent berry with four furrows, having four cells, containing ſeveral ſmall oval ſeeds. There is one ſpecies, a native of the warm parts of America.

FUCUS is uſed for a paint, or compoſition, applied on the face, to beautify it, and heighten the complexion.

Old women make uſe of *fucuſes* and pomatums, to appear young. The *fucus* made with *ceruſs* is corroſive and pernicious to the ſkin.

Pliny ſays, that the *fucus* of the Roman dames was a kind of white earth, or chalk, brought from Chio and Samos, diſſolved in water.

The *fucus Solomonis* is a compoſition of prepared ſublimate, in great repute among the Spaniards of Peru.

FUCUS *Giganteus*, a name given by Mr. Banks and Dr. Solander to a kind of ſea-weed of an enormous ſize, which they diſcovered in their paſſage from Rio de Janeiro to the ſtraight of Le Maire. The leaves of it were four feet long, and ſome of the ſtalks, though not thicker than a man's thumb, above one hundred and twenty.

FUCUS, in *Botany*, the name of a genus of ſubmarine plants of the claſs of *cryptogamia* and order of *alga*; the characters of which are, that they are of a tough ſtructure, and formed into a kind of leaves, which are flat, and variouſly divaricated. The male flowers are veſicles interwoven with ſmall fibres, and the female are veſicles interſperſed with ſmall prominences; they have a ſingle ſeed. See *Tab.* VII. *of Botany, Claſs* 24. N° 3.

The ſpecies of *fucus* enumerated by Mr. Tournefort are ſeventy-ſeven; and by Linnæus are fifty-two.

Mr. Reaumur has diſcovered, that all the *fucuſes* produce regular flowers and ſeeds, in the ſame regular manner. The flowers ſtand all over the leaves from the origin of them at the root to the utmoſt extremities, only the ribs in the middle are free from them. Every flower is compoſed of a cluſter of ſmall and extremely ſlender threads. Theſe are uſually all of the ſame length in the ſame flower, but they are ſo numerous as not to be eaſily counted; the longeſt of theſe threads are not above one twelfth of an inch in length, and the reſt are not half ſo long. They all iſſue out of a ſmall hole in the leaf, which ſerves as a ſort of cup to them. The threads are too feeble to ſupport their own weight in the air. When the ſea has left the plants, they are all found lying flat upon the leaves; though while the water covers them, they ſtand ſomewhat erect. They are not terminated at the top by apices containing a farina; but they may very eaſily contain that powder in their whole ſubſtance, and throw it off as ſoon as they expand themſelves. They are diſpoſed with no ſort of regularity on the leaves; for in ſome places they ſtand very cloſe together, in others they are placed at much greater diſtances. They grow equally on both ſides of the leaves; but the ſame flower never perforates the leaf, but all its parts appear on the ſame ſide. The flowers are much more eaſily diſcerned on the plant when it is dry, than while it is moiſt; for when dry, the filaments that compoſe them are white; whereas when moiſt, they are of a deep brown, like the leaves on which they ſtand. Of all the flowers which cover theſe plants, there are none that produce ſeeds but thoſe which are placed near the extremities of the leaves, and not all of theſe. In thoſe places where the ſeed is beginning to form itſelf, the extremity of the leaf ſwells, and forms a ſort of capſule, which contains the fruit, while the reſt of the leaf retains its former thinneſs. When the flowers are fallen, the holes in the leaf which ſerved them for cups, become eaſily viſible in the places where the thickneſs happens, and where the ſeeds are to be lodged; and the margin of each hole is ſurrounded with a little circular protuberance, which ſtands out beyond the reſt of the ſurface. The ſwelled ends of the leaves grow often to half an inch in thickneſs, and uſually terminate in two horns, which form an acute angle; and the rib of the leaf is not viſible in theſe ſwoln parts. When theſe are cut open, whether it be tranſverſely or horizontally, they are found filled with a thick viſcous liquor, and in this are ſeen ſeveral roundiſh bodies of about a twentieth part of an inch in length; they are of a reddiſh colour, and are eaſily diſtinguiſhed, and are all found to be fixed to the ſide of the leaf. Theſe are what Dr. Robinſon, who ſeems to have been the firſt perſon who diſcovered them, took for the ſeeds; and they have really much the appearance of naked ſeeds; but, when cloſely examined, they are found to be in reality capſules containing each a great number of minute round ſeeds, which are faſtened to their ſides, as they were to the ſides of the tumor in the leaf; and theſe ſmaller capſules are in the ſame manner with thoſe full of a tranſparent viſcous liquor.

Though theſe capſules appear at firſt ſight plain roundiſh bodies; yet when more nearly examined, they are found to be rather ſhaped like glaſs bottles with ſhort necks, the neck being fixed into the ſubſtance of the leaf, and its extremity forming the protuberant circular rim that ſurrounds the little hole in the leaf, which had ſerved as a cup to the flowers. See Mem. Acad. Par. 1711, where we have figures of the *fucus*.

FUCUS *palmatus, handed fucus*, the name given to a ſpecies of ſea *fucus*, diſtinguiſhed from the reſt by its having no ſtalk, its leaves being divided in the manner of a hand, and its extremities divided into many curled ſegments. It is common on almoſt all the ſea coaſts of Europe, and is one of the ſeveral ſpecies of ſea plants in which Mr. Reaumur has diſcovered regular flowers and ſeeds. They are in this ſpecies however ſo ſmall, as to require the aſſiſtance of a microſcope to diſcover them; though after they have been once ſeen in that manner as is the caſe in many microſcopic objects, they may then be eaſily diſtinguiſhed by the naked eye. This plant is faſtened to ſome ſtone by a round root, from which there ariſe four or five leaves, which at about an inch diſtance from the root divide into a number of branchings, which conſtitute the whole plant. This ſpecies carries its ſeeds at the extremities of the leaves, where they are incloſed in the interior ſubſtance of the plant; and nothing is to be diſcovered on the ſurface without the aſſiſtance of glaſſes, unleſs it be that the leaves are of a ſomewhat more duſky hue than elſewhere, which is cauſed by a number of ſmall opake bodies; and when this obſcure part of the plant is opened, there appear a number of ſmall, round, and hard reddiſh ſeeds, which may, probably, be capſules or ſeed-veſſels, and not ſingle ſeeds.

FUCUS *polyſchides*. See POLYSCHIDES

FUCUS *thermalis*, in *Botany*, the name of a remarkable ſpecies of plant, found only in the hot-water ſprings. It was firſt diſcovered by Monſ. de Monteſquieu, in the great baſon, at the boiling ſpring in Gaſcony; he was not able to diſcover that it produced either flowers or ſeeds. Its ſubſtance is entirely compoſed of ſmall bladders full of air, the ſurfaces of which are reticular, as worked in the manner of coarſe canvas. It is obſerved to grow only in the hotteſt waters.

FUDDER, among the *Miners*, a load of lead, which is eight pigs, or ſixteen hundred weight.

FUEL, in *Philoſophy*, the *fabulum* of FIRE, or whatever receives and retains fire, and is conſumed, or rendered inſenſible thereby.

A great deal of nicety is required in chooſing the proper *fuel* to raiſe and continue the ſeveral degrees of fire, in chemical operations. The natural heat of the ſummer ſun is ſufficient for inſolations. A ſpirit-lamp may be made to give the next degree of heat to this, which may be much augmented or decreaſed, according to the number of wicks kept burning at a time.

The next degree of fire to this, is made of the lighter *fuels* ſuch as dry ſtraw, leaves, twigs, and the like; the next in order, is that from oils, wax, reſin, pitch, &c. And laſtly, ſolid wood, coals, and turf, may be employed for the ſtrongeſt. Theſe, by means of proper furnaces made to contain different quantities, may be made to give a greater or leſs degree of a ſtrong fire. To excite the greateſt degree of heat in a furnace, the rule is to uſe the denſeſt *fuel*, and in the largeſt quantity, and to have bellows placed all round the furnace: theſe are to be inceſſantly blown, and directed to the central part of the fire, in which the matter to be worked upon is lodged. Thus the greateſt degree of heat from culinary fire is to be given, and this is ſufficient for the known operations on metals, glaſs, &c.

It is a known truth, that *fuel* cannot conſume by means of heat alone, without the admiſſion of freſh air, and this is no way more clearly proved, than by this eaſy experiment. Let a ſtrong cylinder of iron, hollow within, be fitted with a firm ſcrew at each end; in the cavity of this cylinder incloſe a long piece of charcoal, and then ſcrew up both the ends faſt, and place the whole in a ſtrong fire; let it continue there for ſeveral hours; and when it is taken out and cooled, open it, and the piece of charcoal will be found ſtill black, in its own form, and no way apparently altered or diminiſhed.

It is plain from this, that the conſumption of *fuel* depends

pends upon the rarefaction, diſlodgment, briſk agitation, and diſcharge of its inflammable vapour, by means of freſh air; and hence we have the reaſon of the known rule of extinguiſhing fires by ſmothering them.
It is provided by ſtatute, that wood *fuel* ſhall not be ſelled under the ſize. See BILLET and FAGGOTS.

FUGA *demonum*, in *Botany*, a name uſed by ſome authors for the *hypericum*, or *St.* JOHN'S *wort*.

FUGA *vacui*, in the *Ancient School Philoſophy*, a ſuppoſed averſion in nature to a VACUUM.
Moſt of the phenomena which the ancients aſcribed to the *fuga vacui*, the moderns have demonſtrated to ariſe from the gravity and preſſure of the air. This is the caſe in the aſcent of water in ſyringes, pumps, &c.

FUGALIA, in *Antiquity*, a feaſt celebrated among the Romans, ſuppoſed by ſome to be the ſame with the REGIFUGIUM, held on the 24th of February, in memory of the expulſion of the kings, and the abolithing of the monarchical government. Struvius, Antiq. Rom. Syntag. cap. 9. diſtinguiſhes the *fugalia* from the *regifuge*; and even doubts whether the regifugium were thus called on account of the expulſion of the kings, or becauſe the *rex ſacrorum*, after the ſacrifice was ended, fled haſtily out of the *forum* and *comitia*.
Be this as it will, the only ancient author of note that makes expreſs mention of the *Fugalia*, is St. Auguſtine De Civitate Dei, lib. ii. cap. 6. And his commentator Vives ſhews a great inclination to correct the reading of the word, were it not that St. Auguſtine adds, that the feaſt was a true *Fugalia*, all decency and modeſty being baniſhed from it.
That learned perſon conjectures, that the *Fugalia* were the ſame thing with the *Poplifugia*, or the feaſt of *Fugia*, the goddeſs of joy, occaſioned by the rout of an enemy, which was the reaſon why the people abandoned themſelves to riot and debauchery; and that the feaſt was firſt inſtituted on occaſion of the victory gained over the Fidenates, Fidenates, and neighbouring nations, upon their attempt to take poſſeſſion of Rome, the day after the people had withdrawn from it, as related by Varro, lib. v. de Ling. Lat.
But, according to Varro, the *Poplifugia*, which fell in the month of June, were held in memory of the flight or retreat of the people, in a ſedition raiſed among them: it is true, he adds, that the day followed ſoon after the retreat of the Gauls, and the time when the neighbouring nations conſpired againſt them: but this does not appear to have any relation to the *Poplifugia*, being only meant to mark the æra or time when the ſedition and flight of the Roman people happened. After all, though the *Poplifugia* might have been originally eſtabliſhed in commemoration of the flight of the people, and not that of the enemies, this does not hinder, but the *Fugalia* of St. Auguſtine may probably be the *Poplifugia* of Varro, according to the conjecture of Vives.

FUGAM *facit*, in *Law*, a term uſed where it is found by inquiſition, that a perſon fled for felony, &c. And if flight and felony be found on an indictment for felony, or before the coroner, where a murder is committed, the offender ſhall forfeit all his goods, and the iſſues of his lands, till he is acquitted or pardoned; and it is held, that when one indicted of any capital crime, before juſtices of oyer, &c. is acquitted at his trial, but found to have fled, he ſhall, notwithſtanding his acquittal, forfeit his goods, but not the iſſues of his lands, becauſe by the acquittal the land is diſcharged, and conſequently the iſſues. 3 Inſt. 218. H. P. C. 27. 2 Hawk. P. C. 450.
The party may, in all caſes, except that of the coroner's inqueſt, traverſe the finding of a *fugam facit*; and the particulars of the goods found to be forfeited, may be always traverſed; alſo whenever the indictment againſt a man is inſufficient, the finding of a *fugam fecit* will not hurt him. 2 Hawk. 451. Making default in appearance on indictment, &c. whereby outlawry is awarded, is a flight in law.

FUGITIVE, *refuger*, a perſon obliged to fly his country, or remove from a place where he had ſome abode or eſtabliſhment, on account of his crimes, debts, or on other occaſions.
In the Roman law, a *fugitive* ſlave was ſuch a one as was apt to run away from his maſter. And in ſelling a ſlave, the maſter was obliged to declare, whether or no he were *fugitive*.
The term is alſo applied to deſerters in an army, or thoſe who fly from the combat.

FUGITIVES *goods*, *bona fugitivorum*, the proper goods of him that flies upon felony, which, after the flight lawfully found on record, do belong to the king, or lord of the manor.

FUGITIVES *over ſea*, are perſons that go over ſea without the king's licence, who, unleſs they are merchants, or eminent perſons, or king's ſoldiers, forfeit their goods; and maſters of ſhips, &c. carrying ſuch perſons beyond ſea, ſhall forfeit their veſſels; and alſo, if the ſearcher of any port ſhall negligently ſuffer any perſons to paſs, he ſhall be impriſoned, &c. Stat. 9 Edw. III. cap. 10. and 5 Ric. II. cap. 2.

FUGITIVE *pieces*, among the learned, denote thoſe little compoſitions which are printed on looſe ſheets, or half ſheets; thus called, becauſe eaſily loſt, and ſoon forgot.

FUGUE, *fuga*, *flight*, in *Muſic*, is when the different parts of a muſical compoſition follow each other, each repeating what the firſt had performed.
There are three kinds of *fugues*; the *ſingle fugue*, *double fugue*, and *counterfugue*.

FUGUE, *ſingle*, or *ſimple*, is ſome point conſiſting of 4, 5, 6, or any other number of notes, begun by one ſingle part, and then ſeconded by a third, fourth, fifth, and ſixth part, if the compoſition conſiſts of ſo many, repeating the ſame, or ſuch-like notes; ſo that the ſeveral parts follow, or come in, one after another, in the ſame manner, the leading parts ſtill flying before thoſe which follow.

FUGUE, *double*, is when two or more different points move together in a *fugue*, and are alternately interchanged by ſeveral parts.
For the *Counter* FUGUE, ſee COUNTER-*fugue*.
The Italians ſay, a *fugue* or *flight of rooms*, or *chambers*, meaning a ſeries or range of rooms, the doors whereof anſwer in a right line behind each other, ſo as they may be all ſeen at once, from one extreme to the other.

FULCRUM, *Prop*, in *Mechanics*. See LEVER, and HYPOMOCHLION.

FULGURATING *phoſphorus*, a term uſed by ſome Engliſh writers to expreſs a ſubſtance of the phoſphorous kind, the preparation of which does not ſeem to have been well known to any but the inventor of it. It was prepared both in a liquid and a dry form, and not only ſhone in the dark in both ſtates, but communicated its light to the things it was rubbed on. If incloſed in a glaſs veſſel well ſtopped, it ſometimes would *fulgurate*, or throw out little flaſhes of light, and ſometimes fill the whole vial with waves of flame. It does not need recruiting its light at the fire, or in the ſunſhine, like the phoſphorus of the Bolonian ſtone, but of itſelf continues in a ſtate of ſhining for ſeveral years together, and is ſeen as ſoon as expoſed in the dark; the ſolid or dry matter always reſembling a burning coal of fire, though not conſuming itſelf. Phil. Tranſ. N° 134. See PHOSPHORUS.

FULICA, in *Zoology*. See COOT.

FULIGINOUS, an epithet applied to a thick SMOKE, or vapour, replete with SOOT or other craſs matter.
The work is formed from the Latin *fuligo*, *ſoot*; and is rarely uſed but when joined with vapour.
In the firſt fuſion of lead, there exhales a great deal of *fuliginous* vapour, which, retained and collected, makes what we call LITHARGE.
Lamp-BLACK is what is gathered from the *fuliginous* vapours of pines, and other reſinous woods, when burnt. Some phyſicians talk of *fuliginous* vapours emitted from the ſpleen to the brain, which they will have to be the cauſe of the hypochondriac and hyſteric diſorders; thence called the VAPOURS, and by ſome the SPLEEN.

FULIGO *metallorum*, a term uſed by the *Chemiſts*, ſometimes to expreſs arſenic, and ſometimes crude mercury.

FULIGULA, in *Ornithology*, a name given by Geſner to a ſpecies of duck, ſeeming to be the ſame with a kind common on the Yorkſhire ſhores. The ſame author alſo deſcribes another ſpecies under the name of *anas fuliginoſa prima*, which ſeems the ſame with the CAPO *negro*, or *ſwiſted* DUCK.

FULL is variouſly uſed in oppoſition to empty, narrow, confined, &c.
The Carteſians hold, that the univerſe is *full*, i. e. that every part or point has matter in it.
When the body is *full* of humours it ſhould be purged. See PLENITUDE, and PLETHORA.
An ambaſſador has *full* power given him to act, tranſact, &c. The army was in *full* march, i. e. the whole army was in march, with all the forces it conſiſted of.
A man is ſaid to bear the arms of a family *full*, i. e. without any difference or diminution.

FULL *age*. See AGE, in *Law*.

FULL *arms*. See ARMS.

FULL *forfeiture*. See FORFEITURE.

FULL *moon*, *plenilunium*, that phaſis of the moon, when her whole diſk or face is illuminated; which is in the time of her oppoſition to the ſun.
Eclipſes of the moon always happen at the time of *full* moon. See ECLIPSE.

FULL *and by*, a *Sea-phraſe*, denoting the ſituation of a ſhip with regard to the wind, when ſhe is cloſe-hauled, and ſailing in ſuch a manner, as neither to ſteer too nigh the direction of the wind, nor to deviate to leeward, both

of which movements are unfavourable to her courſe; as in the former her ſails will ſhiver, and render the effort of the wind precarious and ineffectual; and in the latter ſhe will advance in a direction widely diſtant from her real courſe. Hence, keep her *full* is the order from the pilot or other officer to the helms-man, not to incline too much to windward, and thereby ſhake the ſails ſo as to retard the courſe. Falconer.

FULLER, a workman employed in the manufactories, to full, mill, or ſcour cloths, rateens, ſerges, and other woollen ſtuffs, by means of a mill, to render them thicker, and more compact and durable.

The word is formed of the Latin *fullo*, which ſignifies the ſame thing.

The *fullers* among the Romans waſhed, ſcoured, and fitted up cloaths; and their office was judged of that importance, that there were formal laws preſcribed them for the manner of performing it. Such was the Lex Metalla de *Fullonibus*. See alſo Pliny, lib. vii. cap. 56. Ulpian. leg. 12. ff. de Furtis, lib. xiii. § 6. Locati, lib. xix. § 6. ff. &c. See FULLING.

FULLER-*earth*, *ſmectis*, or *cimolia purpurariorum*, is a hard, denſe MARLE, moderately heavy, of a very compact and regular texture, of a rough or dry appearance, though, when cut or ſcraped, it is of a very ſmooth, unctuous, and glaſſy ſurface; it does not colour the hands, adheres but ſlightly to the tongue, melts freely in the mouth, and has a little harſhneſs between the teeth; in water it is immediately diſſolible, and falls into a fine ſoft powder. It makes no effervelcence with aqua fortis; in the fire it acquires a yellowiſh brown colour, and a ſtony hardneſs: the natural colour of the *fullers*-earth is commonly a greyiſh brown; but it much varies, and is found from the pale greyiſh brown to the duſky and almoſt black, generally with a caſt of yellowiſh green. This ſubſtance is of great uſe in the woollen manufacture.

It ſerves to ſcour cloths, ſtuffs, &c. and imbibe the tar employed in the external diſtemperatures of ſheep, and all the greaſe and oil, and other unctuous ſubſtances, neceſſarily uſed in the preparing, dreſſing, &c. of the wool.

Fullers-earth is dug in great plenty out of certain pits near Brick-hill, in Staffordſhire; alſo near Ryegate, in Surry; near Maidſtone, in Kent; near Nutley and Petworth, in Suſſex.

But the greateſt quantity and the fineſt earth of this kind in the world, is dug in the pits at Wavendon, near Woburn, in Bedfordſhire. The ſtrata in theſe pits lie thus; from the ſurface to the depth of ſix yards, there are ſeveral layers or beds of ſand, all reddiſh, but ſome lighter coloured than others. Under theſe there is a thin ſtratum of a ſand-ſtone, which they break through, and then for the depth of about ſeven or eight yards you have ſand again, and then there is the *fullers*-earth. The upper ſtratum of this is about a foot thick, and they call it CLEDGE; this is thrown aſide as uſeleſs, being commonly fouled with the ſand, which originally covered it, and uſually inſinuates itſelf conſiderably into it. After this they come at the fine *fullers*-earth for ſale, which lies to the depth of eight feet more. The matter of this is divided into ſeveral layers, there being commonly about a foot and half between one horizontal fiſſure and another. Of theſe ſeveral layers, the upper half, where the earth breaks itſelf, is tinged red; this ſeems to be owing to the running of the water on it, from among the ſands above, ſome of which are probably of a ferrugineous nature, or have ferrugineous matter among them. This reddiſh *fullers*-earth the workmen call crop; and between the cledge and this, there is a thin ſtratum of matter of leſs than an inch, which in taſte, colour, and external appearance, reſembles the terra Japonica of the ſhops. This may probably alſo have a ſhare in the tinging of the earth, as the water may be coloured in running through it.

The lower half of the ſtrata of *fullers*-earth they call wall-earth; this is untinged with the red colour of the other, and ſeems the moſt proper for fulling. Under the *fullers*-earth there is a ſtratum of a rough and coarſe white ſtone, about two feet thick; they ſeldom dig through this, but if they do, they find more ſtrata of ſand.

The ſtratum of *fullers*-earth ſeems all the way to lie very level, not to riſe and fall with the upper ſtrata, for when the ſurface is higher, they always find they have farther to dig for it. There are a great number of perpendicular fiſſures in the ſtratum of *fullers*-earth, and beſides this, it forms itſelf in every interval into a multitude of pieces of different ſhapes and ſizes by cracking. The place where it is dug, is that ridge of ſand-hills which runs to Shotover, in Oxfordſhire; and as the ſtrata of the earth are uſually found to continue much the ſame, for long tracts of ground, it is probable that the *fullers*-earth ſtratum runs the whole length of theſe hills, and that ſomebody will at one time or other be enriched by finding it in ſome other part of their courſe. Phil. Tranſ. N° 379. or Abridg. vol vi. part ii. p. 220, &c.

It is abſolutely neceſſary to the well dreſſing of cloth; and hence foreigners, though they can procure wool to be clandeſtinely exported out of the kingdom, can never reach to the perfection of the Engliſh cloths, &c. without *fullers*-earth, which is very plentiful in England, and exceis that of other countries in quality, as much as in quantity and cheapneſs.

For this reaſon it is made a contraband commodity; and the export made equally criminal with that of exporting wool.

Abroad they make great uſe of urine, in lieu of *fullers*-earth.

This earth abounds much in the vegetative ſalt which promotes the growth of plants, and is therefore reckoned by ſir H. Plat, and others, a great improver of land. When mixed with vinegar, it diſperſes pimples and puſhes, checks inflammations, and cures burns. See CIMOLIA.

FULLERS-*weed*, *thiſtle*, or *teaſle*, in *Botany*. See TEAZEL.

FULLERY, a work-houſe, or place where cloths, &c. are *fulled* or ſcoured.

The term is principally underſtood of the fulling-mill.

FULLING, the art, or act of cleanſing, ſcouring, and preſſing cloths, ſtuffs, and ſtockings, to render them ſtronger, cloſer, and firmer: called alſo *milling*.

Pliny, lib. vii. cap. 56. aſſures us, that one Nicias, the ſon of Hermias, was the firſt inventor of the art of *fulling*: and it appears by an inſcription quoted by ſir G. Wheeler, in his Travels through Greece, that this ſame Nicias was a governor in Greece in the time of the Romans.

The *fulling* of cloths, and other ſtuffs, is performed by a kind of water-mill; thence called a *fulling*, or *ſcouring-mill*.

Theſe mills, excepting in what relates to the mill-ſtones and hopper, are much the ſame with corn-mills. And there are even ſome which ſerve indifferently for both purpoſes; corn being ground, and cloths fulled, by the motion of the ſame wheel.

Hence in ſome places, particularly France, the fullers are called *millers*; as grinding corn and milling ſtuffs at the ſame time.

The principal parts of the *fulling-mill* are, the wheel with its trundle; which gives motion to the tree or ſpindle, whoſe teeth communicate it to the peſtles, or ſtampers, which are hereby raiſed and depreſſed alternately, according as its teeth catch on, or quit, a kind of latch in the middle of each peſtle. The peſtles, and troughs are of wood: each trough having at leaſt two, ſometimes three peſtles, at the diſcretion of the maſter, and according to the force of the ſtream of water.

In theſe troughs are laid the cloths, ſtuffs, &c. intended to be *fulled*: then, letting the current of water fall on the wheel, the peſtles are ſucceſſively let fall thereon, and by their weight and velocity they ſtamp and preſs the ſtuffs very ſtrongly, which by this means become thickened and condenſed.

In the courſe of the operation, they ſometimes make uſe of urine, ſometimes of fullers-earth, and ſometimes of ſoap.

To prepare the ſtuffs to receive the firſt impreſſions of the peſtle, they are uſually laid in urine; then in fullers-earth and water; and laſtly in ſoap, diſſolved in hot water.

Soap alone would do very well, but this is expenſive; though fullers-earth, in the way of our dreſſing, is ſuperior to it; but then it muſt be firſt well cleared of all ſtones and grittineſs, which are apt to make holes in the ſtuff.

As to urine, it is certainly prejudicial, and ought to be entirely diſcarded; not ſo much on account of its ill ſmell, as of its ſharpneſs and ſaltneſs; which is apt to render the ſtuffs dry and harſh.

The true method of *fulling* with ſoap is delivered by Monſ. Colmet, in an authentic memoir on that ſubject, ſupported by experiments made by order of the marquis de Louvois, then ſuperintendant of the arts and manufactories of France. The ſubſtance of which we ſhall here ſubjoin.

FULLING, *cloth and woollen ſtuffs, with ſoap, method of.* A coloured piece of cloth, about forty-five ells, is to be laid in the uſual manner, in the trough of a *fulling-mill*, without firſt ſoaking it in water, as is commonly practiſed in many places.

To *full* this trough of cloth, fifteen pounds of ſoap are required; one half of which is to be diſſolved in two pails of river or ſpring-water, made as hot as the hand can well bear it. This ſolution is to be poured by little and little upon the cloth, in proportion as it is laid in the trough;

trough: and thus it is to be *fulled* for at leaſt two hours; after which it is to be taken out, and ſtretched.

This done, the cloth is immediately returned into the ſame trough, without any freſh ſoap; and there *fulled* two hours more. Then taking it out, they wring it well, to expreſs all the greaſe and filth.

After the ſecond *fulling*, the remainder of the ſoap is melted, as the former, and caſt out four different times, on the cloth; remembering to take out the cloth every two hours, to ſtretch it, and undo the plaits and wrinkles which it has acquired in the trough. When they perceive it ſufficiently *fulled*, and brought to the quality and thickneſs required, they ſcour it out for the laſt time in hot water, keeping it in the trough till it be quite clean.

As to white cloths; becauſe theſe *full* more eaſily, and in leſs time, than coloured ones, a third part of the ſoap may be ſpared.

FULLING *of ſtockings, caps, &c.* may be performed ſomewhat differently; viz. either with the feet, or the hands; on a kind of rack, or wooden machine, either armed with teeth of the ſame matter, or elſe with horſes or bullocks teeth.

The ingredients made uſe of herein, are urine, green ſoap, white ſoap, and fullers-earth. But water ſoftened with chalk is far preferable.

Note, woven ſtockings, &c. ſhould be *fulled* with ſoap alone; for thoſe that are knit, fullers-earth may be uſed with the ſoap.

Indeed, it is frequent to *full* theſe kinds of works with the mill, after the uſual manner, of cloths, &c. But that is too coarſe and violent a manner, and is apt to damage the work, unleſs it be very ſtrong.

FULLO, in *Ichthyology*, a name given by Theodore Gaza, and others to the TENCH, or black *oprinus*, called by the Greeks *pſylon*.

FULLONIANI, in *Church Hiſtory*, heretics who anathematized all who did not acknowledge, that Chriſt ſuffered in his divine nature; or who diſtinguiſhed his human and paſſible nature from his divine and impaſſible. See THEOPASCHITES.

FULLONICA *terra alba*, white *fuller's* earth, in *Natural Hiſtory*, a name given by ſome authors to the common white tobacco-pipe clay. See CIMOLIA *alba*.

FULLONUM *cardous*. See TEAZEL.

FULMAR, in *Ornithology*, a ſpecies of *procellaria* or *petrel*, that inhabits the iſle of St. Kilda; appearing there in November and continuing through the whole year, except the months of September and October. It lays a large white and brittle egg, which is hatched in June. This bird is ſuperior in ſize to the common gull; the bill is ſtrong, hooked at the end, and of a yellow colour. The noſtrils are compoſed of two large tubes, lodged in one ſheath; the head, neck, inferior part of the body, and tail are white; the back and coverts of the wings aſh-coloured; the quill-feathers duſky, and the legs yelloviſh. Inſtead of a back-toe, it has only a ſort of ſpur, or ſharp ſtraight nail. The food of theſe birds is the blubber or fat of whales, of which they are very voracious; inſomuch that the whales are diſcovered at ſea by the flights of theſe birds; this is ſoon converted into oil and ſpouted from their bills in large quantities for their defence and for the ſupply of their young. This oil, it is ſaid, has been ſucceſsfully uſed in rheumatic caſes. The *fulmar* is of ſingular uſe to the iſlanders, as it ſupplies them with oil for their lamps, down for their beds, a delicacy for their tables, a balm for their wounds, and a medicine for their diſeaſes. The *fulmor* is alſo a certain prognoſticator of the change of the wind; becauſe, if it comes to land, no weſt wind is expected for ſome time; and the contrary, when it returns and keeps at ſea. Pennant.

FULMINANT, FULMINANS, or FULMINATING, an epithet applied to ſomething that thunders, or makes a noiſe like that of thunder.

We ſay, *Jupiter* fulminans, *aurum* fulminans, *pulvis* fulminans, *&c.* The *Jupiter fulminans* and the *Jupiter fulgurator* ſeem to have been very much of the ſame kind: but if they are diſtinguiſhed, we may conſider the former as the diſpenſer of the lightnings which are darted from the clouds, and the latter as the diſpenſer of thoſe leſſer lightnings that only ſhoot about and ſtruggle amidſt the clouds.

FULMINANS, *Aurum*. See AURUM.

FULMINANS, *Pulvis*, is a compoſition of three parts of nitre, two parts of ſalt of tartar, and one of ſulphur.

Both the *aurum* and *pulvis fulminans* produce their effect principally downwards: in which they differ from gunpowder, which acts *in orbem*; but principally upwards. If they be laid in braſs ladles, and ſo ſet on fire; after fulmination, the ladles will be found often perforated. Moreover, this powder does not require to be forcibly confined, as gun-powder does, in order to make a great exploſion, and the heat muſt be applied to it ſlowly. We may alſo obſerve that ſome inſtants before its exploſion, a light blue flame appears on its ſurface, which is nothing elſe than the phlogiſtic vapours beginning to kindle. No more fire or flame is perceived during its fulmination; the exploſion being ſo quick and the commotion ſo violent, that the flame is ſuffocated and extinguiſhed as ſoon as it is formed and before it can be perceived. Nor does the *fulminating* powder generally kindle the combuſtible bodies in contact with it, becauſe the time of its inflammation is too ſhort.

FULMINATING *damp*. See DAMP.

FULMINATING *Legion*. See THUNDERING *Legion*.

FULMINATION, in the *Romiſh Canon Law*, a ſentence of a biſhop, official, or other eccleſiaſtic appointed by the pope; whereby it is decreed, that ſome bull, diſpenſation, or reſcript, ſent from the pope, ſhall be executed.

Fulmination is the ſame thing with the verification, or recognition, of a letter, or inſtrument, of a prince in a lay court.

FULMINATION is alſo uſed for the denunciation, or execution, of a ſentence of ANATHEMA, made in public, with due ſolemnity.

In *fulminating* anathemas, the biſhop who pronounces ſentence, is to be clothed in his epiſcopalia, and accompanied with two prieſts in ſurplices; after ſentence is pronounced, they caſt down to the ground the lighted wax-tapers which they held in their hands.

FULMINATING, or FULGURATION, in *Chemiſtry*, a vehement noiſe, or ſhock reſembling thunder, occaſioned by the ſudden exploſion and inflammation of divers preparations; as *aurum fulminans*, *&c.* when ſet on fire.

FULUS CULUM, in *Botany*, a name given by the ancient Romans to a peculiar ſpecies of mullein or *verbaſcum*, of which they uſed to make the wicks of the torches with which they kindled their funeral piles. The Greeks for the ſame reaſon called this ſpecies *necnia*. Dioſcorides indeed calls it *lychnitis*, λυχνίτις; and Nicander, *thrypſilis*, θρυψίλις. The way they uſed it was this: they beat out the ſtalk of the plant, as we do hemp, and when it was ſeparated into looſe fibres, they plunged it into melted reſin; this gave it a conſiſtence again, and when cold, it was a kind of flambeau.

FUMADOES, in *Commerce*, a name given to pilchards, garbaged and ſalted, then hung in the ſmoak and preſſed; ſo called in Spain and Italy, whither they are exported in great abundance. Vide Stat. 14 Car. 2. cap. 31.

FUMAGE, a term uſed in ſome parts of the kingdom, for dung, or manuring with dung.

FUMAGE. See FUAGE.

FUMARIA, ſee FUMITORY.

FUMER, in *Zoology*, ſee POLE-*cat*.

FUMET, a term uſed among ſportſmen for the ordure or dung of harts; otherwiſe called fewmets.

FUMIGATION, in *Medicine* and *Chemiſtry*, is underſtood of things taken in the way of ſume, or ſmoke; or that are turned into ſmoke or ſteam.

The *fumigations* preſcribed by diſpenſatory writers are reduced to two kinds; the one conducive to health, the other only to pleaſure; and of each kind ſome are of moiſt, or liquid ingredients, others of *dry* ones.

The *fumigation* for pleaſure are compoſed of fragrant and ſweet-ſcented ſubſtances, and are uſed in form of powders, troches, or medicated candles. The firſt are uſually prepared of ſtorax, benjamin, lignum aloes, cinnamon, camphor, muſk, ambergriſe, and civet, mixed in due quantities, and all reduced together to a powder. The ſecond kind, or troches, are compoſed of the ſame kind of powdered ingredients, and are made into a paſte with a mucilage of gum tragacanth, and then cut into form. And the laſt kind, or candle *fumigations*, are prepared of the melted ſweet gums, with labdanum, made up into the form of large candles, with as much of the before mentioned ſweet ingredients as can be received into the maſs. Theſe, though only meant for luxury and pleaſure, yet have medicinal virtues: and as they abound in cordial ſubſtances, cannot but revive the ſpirits, and reſiſt contagion. The moiſt *fumigations* of this kind conſiſt of the powders before named, blended among a large quantity of roſe and orange-flower water, and of ſolutions of ſtorax, and other of the ſweet gums in ſpirit of wine.

The *fumigations* uſed to reſtore health are of ſeveral kinds. Some are meant only as corroboratives, and theſe are compoſed of much the ſame ingredients with thoſe uſed for pleaſure; others are uſed to dry up abundant humours, to purge the lungs, or to promote the menſes. In all diſorders of the uterus, there ſhould be added to theſe *fumigations*, galbanum, caſtor, and aſſa fœtida. A common *fumigation* is alſo uſed, by throwing tobacco on coals, and receiving the ſmoke through a funnel; and to this are ſometimes added colt's foot leaves, with other pectoral herbs, and a little ſulphur. Theſe are very uſeful for drying up ulcerations of the lungs, and other diſorders of the breaſt.

The

The moiſt *fumigations*, for the ſake of health, conſiſt either of ſome ſimple liquor, ſuch as vinegar, wine, aqua vitæ, or roſe-water; and in ſome caſes, as for the diſcuſſing hard tumors, a red hot brick, or ſtone, is thrown into vinegar, and the ſteam is received on the part. This is alſo a *fumigation* often uſed in times of peſtilential contagion, and that with great ſucceſs. Decoctions of uterine herbs are alſo frequently uſed for *fumigations* in ſeveral diſorders of the womb.

Olibanum, amber, ſtorax, and balſam of Tolu, make a fine dry *fumigation* for a catarrh: and in hyſteric caſes, great benefit is often found from holding the head, with the mouth open, over a hot ſolution of an ounce of aſſa-fœtida in a pint of ſtrong wine-vinegar.

A northern phyſician has an expreſs treatiſe to juſtify the uſe of *fumigations* in many caſes.

It is dangerous taking mercury by *fumigation*. This *fumigation* is a kind of potential calcination; the vapour of mercury, laid on the fire, corroding and reducing into a calx the little laminæ of metals ſuſpended over it.

Fumigations with cinnabar have often been recommended as very efficacious in ſome of the worſt circumſtances of the venereal diſeaſe. From a caſe related in the Medic. Eſſ. Edinb. vol. iv. art. 8. it appears, that this practice may be attended with very violent effects. Half a dram of factitious cinnabar burnt under the noſe and mouth of the patient, is there mentioned as having raiſed a ſpitting in three hours.

FUMIGATION, *powder of*, was invented at Moſcow, in 1771, for preventing the infection of the plague. It is prepared of different degrees of ſtrength in the following manner: 1. Take leaves of juniper, juniper-berries pounded, ears of wheat, guaiacum wood pounded, or, if this cannot be had, the cones of pines or firs, of each ſix pounds; common ſalt-petre pounded, eight pounds; ſulphur pounded, ſix pounds; Smyrna tar or myrrh, or inſtead of this, the common tar of pines and firs, two pounds; mix all theſe ingredients together, and they will produce a POOD of the powder of the firſt ſtrength. 2. Take ſouthernwood or mugwort, cut into ſmall pieces, five pounds; leaves of juniper, cut in the ſame manner, four pounds; juniper-berries pounded, three pounds; common ſalt-petre pounded, four pounds; ſulphur pounded, two pounds and a half; Smyrna tar or myrrh, one pound and a half; mix theſe together, and they will yield half a POOD of the powder of the ſecond ſtrength. The efficacy of the powder of *fumigation* was tried on ten malefactors under ſentence of death, who were confined three weeks in a lazaretto, and expoſed in every poſſible way to the infection of the plague, and none of them were at all injured by it.

FUMIGATION is alſo uſed for the act of making a ſuſpended body receive the fumes or ſteams of one or more other bodies, in order to calcine it, to correct it, or impart to it ſome new quality.

Ceruſs is made by the *fumigation*, or vapour, of vinegar, gnawing and corroding plates of lead.

FUMIGATOR, formed of *fumus*, *facio*, in *Surgery*, an inſtrument uſed for injecting clyſters of the ſmoke of tobacco. Clyſters of this kind have been applied in the ILIAC *paſſion*, in the HERNIA *incarcerata*, and in other caſes of an obſtinate conſtipation, or obſtruction of the bowels; and as they are admirably adapted to excite the ſuſpended or extremely languid periſtaltic motion of the inteſtines, which are reckoned among the moſt irritable parts of the body, and are allowed to retain the vital influence longer than any other, they have been peculiarly ſerviceable in caſes of recovery from apparent death by DROWNING, &c. The inſtrument commonly uſed for the injection of theſe clyſters is formed with an iron or braſs capſula for containing a certain quantity of tobacco, to which capſula are faſtened two pipes; one of them made of bone, to be inſerted into the anus; and the other of ivory, in the ſhape of that end of the trumpet which is applied to the mouth; by means of which the ſmoke of the burning tobacco in the capſula is forced through the firſt pipe into the anus. The Dutch have made the bowl of this inſtrument large enough to contain three fourths of an ounce of tobacco; it is conſtructed of wood, lined with braſs or tin, and covered by a top of wood lined in the ſame manner; the top is ſcrewed upon the other; the inſtrument is uſed by means of a wooden tube or blow-pipe, ſcrewed to the top, and adapted either to the mouth, or to a pair of bellows. The inſtrument uſed by the French is compoſed of a box reſembling the bowl of a pipe, covered by a lid, at the upper part of which is a hole or chimney, for giving air to the tobacco at pleaſure. From the ſide of this cover proceeds a tube, about four inches in length, incorporated with it, and adapted at the other extremity to the end of a flexible tube. At the lower part of this box is inſerted a kind of tubular handle, which admits the nozzle of a pair of bellows, faſtened to it by means of an iron pin paſſing tranſverſely through both. By this contrivance, when the tobacco is lighted, it is not neceſſary to touch the heated box; and the bellows ſerves as a handle by which to direct all the neceſſary movements: the whole inſtrument is made of copper.

Mr. Wrigleſworth, in conſequence of hints and obſervations communicated to him by Dr. Cogan, has conſtructed a *fumigator* free from the inconveniencies attending thoſe already mentioned. The bowl or body of this new inſtrument is made of caſt braſs, and is large enough to contain about an ounce and a half of tobacco. The pipe projecting from the lower part of it is bored out of a ſolid piece of braſs, and alſo thoſe to which each extremity of the leathern tube is affixed. The cover is likewiſe made of caſt braſs; from the upper extremity of which projects a neck about an inch and a half in length, the opening or bore of it being about half an inch in diameter. The cover is fixed to the box by means of two niches made on each ſide of a circular ridge or edge, admitting two ears, that project from the upper part of the box, which by a circular motion lock upon the brim. The nozzle of the bellows is accurately adapted to the neck of the cover, and is about an inch and a half or two inches long; the lower end of the nozzle is rounded and ſmooth, like the lower extremity of a glyſter-pipe, and perforated like a cullender, in order to prevent the aſhes of the tobacco from riſing into the bellows. The bellows are faſtened upon the cover or lid in a manner ſimilar to the preceding; an ear projects from the upper part of the neck, and is admitted into a nitch, in a circular rim, upon the nozzle. The pipe projecting from the lower extremity of the bowl, locks into the croſs-pipe to which the leathern tube is affixed, in the manner of a bayonet. By this kind of faſtening the whole apparatus may be made ready in the ſpace of a minute, and forms one compact body, free from the hazard of falling in pieces, and thus interrupting the operation; and yet either part may be taken off when the occaſion requires, with the utmoſt eaſe and expedition. The bowl is incloſed in a thick caſe of wood, removeable at pleaſure; which ſecures the hand from injury during the whole proceſs. The ſame ingenious artiſt has alſo conſtructed a machine ſo formed, as to contain the above deſcribed *fumigator*, with every requiſite for beginning an operation in the recovery of perſons apparently drowned, &c. ſuch as brandy, ſalt, ſpirit of ſal ammoniac, tinder-box, flint and ſteel, and cloths to rub the body. This machine is light and portable, being not much larger than a caſe of ſurgical inſtruments. Reports of the Humane Society, 1775. p. 82, &c.

FUMING, in *Metallurgy*, the firſt calcination of the ores of metals, intended to diveſt them of their ſulphurs. See ROASTING.

FUMITORY, *Fumaria*, in *Botany*, a genus of the *diadelphia hexandria* claſs: the empalement of the flower is compoſed of two equal oppoſite leaves; the flower is of the ringent kind, approaching nearly to the butterfly flowers; the upper lip is plain, obtuſe, and reflexed; the nectarium at the baſe is obtuſe and little prominent; the under lip is like the upper; but the baſe is keel-ſhaped: the chaps of the flower are four-cornered, and perpendicularly bifid; there are two equal broad ſtamina in each flower, included in the two lips, each being terminated by three ſummits. In the centre is ſituated an oblong germen, which afterwards becomes a ſhort pod with one cell, including roundiſh ſeeds. There are twelve ſpecies. Miller.

The common *fumitory*, which is frequent in our gardens and corn-fields, and flowers from April to June, is eſteemed a very great medicine in obſtructions of the liver and ſpleen; it attenuates ſcrous, bilious, and aduſt humours, and carries them gently off by ſtool and urine. It is famous for the ſcurvy, and is alſo given in infuſion in the jaundice, and in the itch, and all other cutaneous diſorders.

FUNAMBULUS, among the Romans, was what we call a *rope-DANCER*, and the Greeks, *ſchœnobates*.

The term is alſo uſed for ſuch as, letting themſelves down by a rope, or cord, make their eſcape out of a city, or place beſieged, as is obſerved by Du-Cange.

Julius Capitolinus, and Horace, make mention of *funambuli*. Acron on Horace aſſures us, that it was the orator Meſſala who firſt introduced the word *funambulus*, in lieu of *ſchœnobates*, uſed by the Greeks. For the Greeks ſeem to have had ſome of theſe rope-dancers from the firſt inſtitution of their ſcenic games, which are ſaid to have been invented about the time of Icarius, father of Erigone; or of Dionyſius, ſurnamed Liber Pater, whom Theſeus firſt introduced into Athens.

At Rome, the *funambuli* firſt appeared under the conſulate of Sulpicius Panucus and Licinius Stolo, who were

the firſt introducers of the ſcenic repreſentations. It is added, that they were firſt exhibited in the iſland of the Tiber; and that the conſors Meſſala and Caſſius afterwards promoted them to the theatre.

In the *Floralia*, or *ludi Florales*, held under Golba, there were *funambulatory* elephants, as we are informed by Suetonius. Nero alſo ſhewed the like, in honour of his mother Agrippina. Vopiſcus relates the ſame of the time of Carinus and Numerianus.

There was a *funambulus*, it ſeems, who performed at the time when the Hecyra of Terence was acted; and the poet complains, that the ſpectacle prevented the people from attending to his comedy; *Ita populus ſtudio ſtupidus in funambulo animum occupârat.*

FUNCTION, the act of doing ſomething for which the agent was appointed, or which he was obliged to.

Thus we ſay, the ſtomach performs its *function*, i. e. digeſts well; the fumes of wine diſturb the brain in the performance of its *functions*.

Phyſicians divide the *functions* of the human body into *vital*, *natural*, and *animal*.

FUNCTIONS, *vital*, are thoſe neceſſary to life; and without which it cannot ſubſiſt: *as*, the actions of the heart, brain, lungs, &c.

FUNCTIONS, *natural*, are thoſe which change the food, &c. ſo as to aſſimilate it to our own nature: ſuch are the actions of the viſcera, and the veſſels which receive, retain, ſecern, &c. the humours.

FUNCTIONS, *animal*, are thoſe without which we cannot perceive, will, remember, &c. Such are feeling, ſeeing, imagining, judging, paſſions, voluntary motion, &c.

FUNCTION is alſo uſed figuratively in ſpeaking of the offices, duties, or occupations a perſon is engaged in.

The actions of an ambaſſador muſt be diſtinguiſhed from his *functions*; the one regards his character, the other his perſon.

FUNCTION. The term *function* is uſed in algebra, for an analytical expreſſion any way compounded of a variable quantity, and of numbers, or conſtant quantities: therefore every analytical expreſſion, in which, beſides a variable quantity x, there are conſtant quantities, is a *function* of x. Thus $a+3x$, $x-4xx$, $ax+b\sqrt{aa-xx}$, c^x, &c. are *functions* of x.

The difference of *functions* conſiſts in the manner in which they are compounded; and depends, therefore, upon the operations by which quantities may be compounded and mixed. Theſe operations are, addition, ſubſtraction, multiplication, and diviſion, the raiſing to powers, and extraction of roots, to which the reſolution of equations ought to be referred. Beſide theſe operations, which are called algebraical, there are other tranſcendental ones; ſuch as exponential, logarithmic, and many others, ariſing from the inverſe method of fluxions.

Functions may ariſe from the moſt ſimple and analytical operations: thus we have the multiple *functions* $2x$, $3x$, $\frac{1}{2}x$, ax, &c. and the powers of x, as x^2, x^3, $x^{\frac{1}{2}}$, x^{-1}, &c. are called *functions*.

Functions are divided into *algebraical* and *tranſcendental*: *algebraical functions* are thoſe formed by algebraic operations only; ſuch are thoſe above ſpecified, except c^x, which belongs to the following ſpecies.

Tranſcendental functions are thoſe formed by tranſcendental operations: ſuch are exponential quantities or powers, the exponents of which are variable quantities; whereas, in algebraic *functions* the exponents are always conſtant quantities.

It is to be obſerved as to *tranſcendental functions*, that thoſe *functions* only of a variable quantity are to be deemed tranſcendental, which not only enter the compoſition with, but alſo effect the variable quantity: thus if π ſignifies a circular arc, or a logarithm, then will e^π, and the like expreſſions, be *tranſcendental functions* of π. But if the tranſcendental operation appertains only to conſtant quantities, the *function* is no more than algebraic: thus if c denote the circumference of a circle, the radius of which is $=1$, c will be a tranſcendental quantity, and yet the expreſſions $c+x$, cx^3, $\frac{4x^3}{c}$ are but algebraic *functions* of x. Some indeed have doubted whether c^x ought to be ranked among algebraic *functions*, or not; but the doubt is of ſmall weight. And ſome chooſe to call the powers of x, the exponents of which are irrational numbers, *interſcendent functions*: thus, $x^{\sqrt{2}}$ is an interſcendent *function* of x.

On the ſubject of *functions*, their diviſions, tranſformations, explication by infinite ſeries, &c. Mr. Euler ſhould be conſulted, who has treated this matter very fully in the firſt chapter of his Analyſ. Infinitorum.

FUND. FUNDUS, a Latin term, uſed for the bottom of certain things; and particularly of certain parts of the body.

FUND *of the eye*, FUNDUS *oculi*, is that part poſſeſſed by the choroides and retina.

The images of objects are repreſented in an inverted ſituation, in the *fund* of the eye. See VISION.

FUNDUS *uteri*, or *bottom of the womb*, is the body or principal part thereof; ſo called in contradiſtinction to the cervix, or neck; the oſculum, or mouth; and the vagina, or ſheath. See *Tab. Anat.* (*Splanch.*) *fig.* 9. *lit. a. fig.* 11 *lit. d.*

FUNDUS *veſicæ*, or *bottom of the bladder*, is the cavity thereof, wherein the urine is contained. In man it is placed over the rectum; and in women over the matrix.

FUND *of the gall bladder*, *the ſtomach*, &c. See GALL-*bladder*, STOMACH, &c.

FUNDUS *plantæ* is that part of a plant, where the ſtalk juſt meets and joins the root.

FUNDUS *cœli* is the point oppoſite to the point of culmination; or the point of the ecliptic, wherein it is interſected by the meridian beneath the horizon.

FUND, in *Commerce*, is uſed for the capital or ſtock of a merchant, company, or corporation; or the ſum of money that they put into trade.

In this ſenſe we ſay abſolutely, the *funds*, the public *funds*, meaning the ſtock of the great companies, or corporations, as the Bank, South-ſea, Eaſt-India, &c.

FUNDS, *public*, are the taxes appropriated by parliament to the ſupport of civil government, and the payment of the principal and intereſt of money borrowed for public ſervices. Theſe *funds* in Britain, have been all formed into the four following claſſes or diviſions: the AGGREGATE *fund*, the SOUTH SEA *Fund*, the GENERAL *Fund*, and the SINKING *Fund*. Of all theſe, but more eſpecially the laſt, we ſhall give an account in the order in which they have been now named.

The *aggregate fund* was eſtabliſhed by an act of Geo. I. cap. 12. in 1715. It had this name given it, becauſe it conſiſted of a great variety of taxes and ſurpluſſes of taxes and duties which were in that year conſolidated, and given as a ſecurity for the diſcharge of the intereſt and principal of debts due to the Bank of England, and ſome other public debts; and alſo for the payment of 120,000*l.* per ann. to the civil liſt. Into this *fund* are brought the two thirds and one half ſubſidy or tonnage and poundage; half the inland duties on tea and coffee; the houſe money granted by the 7th of Will. III. the duty on hops; the duties on low wines, brandy, and Britiſh ſpirits; all arrears of land taxes; all public monies not appropriated; the ſurpluſſes of the nine penny exciſe, of the five ſeveniths of the Bank nine penny exciſe, of the revenues in the annuity acts of the 4th, 5th, and 6th of queen Anne, &c. and, by an act of the 1ſt. of Geo. II. all the duties conſtituting the revenue of the civil liſt. The whole produce or income of this *fund* had been for a few years before 1778 about 2,600,000*l.* per ann.

The *South-ſea fund* was eſtabliſhed, by ſtat. 3 Geo. I. cap. 9 in 1716; and is ſo called, becauſe appropriated to pay the intereſt of the South-ſea company's capital. It conſiſts of a duty on candles, and certain imports on wines, vinegar, tobacco, and Eaſt India goods. Its produce of late has been about half a million per ann.

The *general fund* was alſo eſtabliſhed, by ſtat. 3 Geo. I. cap. 7. in 1716, and conſiſts of a ſurplus on goods exported; a tax on hackney-coaches and chairs; duties on ſoap, hides, ſtamps, and policies of inſurance; 700*l.* per week letter-money; a moiety of the inland duties on tea and coffee; and 39 85*l.* per annum out of the hereditary exciſe on beer for bankers annuities. All theſe taxes and payments have for ſome years amounted to a little more than a million per ann. and are appropriated to the diſcharge of the intereſt of 7,808,087*l.* (originally 10,000,000*l.*) capital ſtock of South-ſea annuities, together with charges of management.

All that remained of the produce of the taxes thus digeſted into theſe three *funds*, after ſatisfying the charges upon them, was in the ſame year (or 1716) carried into a fourth *fund*, to which was given the name of the *ſinking fund*, becauſe appropriated to the purpoſe of ſinking the public debts. The words of the act of the 3d of Geo. I. which eſtabliſhed this *fund*, are, "All the mo-"nies to ariſe from time to time, as well of the exceſs "and ſurplus of an act made this ſeſſion for redeeming "the *funds* of the Bank of England; and of the exceſs "or ſurplus by virtue of one other act made likewiſe "this ſeſſion for redeeming the *funds* of the South-ſea "company; as alſo, of the exceſs or ſurplus of the du-"ties and revenues by this act appropriated as afore-"ſaid; and the overplus monies of the ſaid *general fund* "by this act eſtabliſhed; ſhall be appropriated to the "diſcharging the principal and intereſt of ſuch national "debts as were incurred before the 25th of December, "1716, and are declared to be national debts; and to "or for no other uſe, intent, or purpoſe whatſoever."

The operations and progreſs of this *ſinking fund* form ſo

important a part of the hiſtory of Britain, that a more particular account of it will be here proper.

Before its eſtabliſhment there had exiſted many ſmaller *funds* of the ſame nature; that is, ſuch duties or taxes had been provided for paying the intereſts of particular loans, as afforded ſurpluſſes by which the principal itſelf was to be gradually redeemed: this was the common practice in the reigns of king William and queen Anne. Moſt of the public duties were given for terms of years; and at the end of thoſe terms they ceaſed of courſe, unleſs continued for farther terms by new acts of parliament: and, in general, it was provided, when any money was raiſed, that the principal ſhould be cancelled either by time, as in the caſe of the ſale of long and ſhort annuities, or by the ſurpluſſes of the duties charged with the payment of the intereſt. This was an excellent plan, but it was by no means carried ſteadily into execution. In the year 1720, moſt of the long and ſhort annuities were converted into redeemable perpetuities, at the expence of above three millions; and the ſurpluſſes of the duties charged with particular loans were often ſo broken into, by being either charged with new loans before they had cancelled the old, or ſpent on current ſervices, as to be rendered incapable of anſwering the end intended by them. In conſequence partly of this bad management, the public debts at the acceſſion of the houſe of Hanover were ſo much increaſed as to be generally reckoned inſupportable; and their reduction was made one of the firſt objects of parliamentary attention. This gave riſe, in 1716, to the inſtitution of the *ſinking fund* of which we are giving an account; the father of which (as has been generally ſaid) ſir Robert Walpole, but, in reality, the earl of Stanhope. All the taxes, except the land-tax, and five pence per buſhel malt-tax, were now made perpetual, and diſtributed into the three *funds* which have been deſcribed, the ſurpluſſes of which, for ever afterwards, were to be held ſacred, and to be applied inviolably, according to the words of the act juſt recited, to the redemption of the national debt. Theſe taxes have been always voted by parliament from year to year: they are, on this account, diſtinguiſhed by the name of the annual taxes, and wholly employed, as far as they will go, in bearing the current expences of every year.

A conſiderate perſon might have ſuſpected, that the ſame cauſes which had rendered former partial appropriations ineffectual, would deſtroy the efficacy of this. There ſeemed, however, to be reaſon for hoping the contrary: for,

Firſt, the future happineſs and glory of the kingdom were thought to depend on this appropriation; and the law which eſtabliſhed it was declared to be a fundamental law of the realm. In conſormity to this, ſecondly, the words of this law were made as ſtrong as they could well be; and, in order to give additional force to it, a repetition of it, in the ſame words, was inſerted in an act of the 5th of Geo. I. cap. 3. Particular notice ſhould be taken of theſe words: they order that all the ſurpluſſes of the taxes then made perpetual, ſhall be applied to the diſcharge of the public debts, and "to no other uſe or "intent whatever." When, therefore, a debt had been paid off, the addition ariſing from that payment to the ſurpluſſes (or the annuity diſengaged by it) became a part of the *fund*, and, together with it, was to be employed in diſcharging farther debts. And the ſame being true of every ſucceſſive annuity diſengaged by every payment, the *fund*, if never miſapplied, muſt neceſſarily have operated in ſinking the public debt, in the ſame manner that money accumulates, when put out to bear compound intereſt. And in this way this *fund* did in fact operate for a few years. While in its infancy, it was watched over with great care: the improvement, and the inviolable application of it, were recommended in moſt of the ſpeeches from the throne, and echoed back in the addreſſes of the houſe of commons. It is particularly obſervable, that ſo well did our miniſters then underſtand the nature and importance of this *fund*, that rather than encroach upon it, they frequently borrowed money in order to defray the neceſſary expences of government. From ſome publications in 1726 it appears, that ſome perſons had been led to apprehend this zeal of the miniſtry would not be permanent, becauſe it was not their intereſt to pay off the public debt, on account of the dependence and influence created by it. In anſwering this objection, the writers on the ſide of the court called ſuch an apprehenſion an indecent jealouſy, and took upon them to aſſure the public, "that in no "poſſible exigence of affairs could our miniſters ever "approve of or recommend the alienation of the *ſinking* "*fund*." Happy would it have been for Britain had this proved true: but in a little time it appeared, that the apprehenſions which had been ſtyled indecent jealouſies, were too well grounded. Men in power came ſoon to ſee, that this *fund* was advancing too faſt in its operations, and to change their zeal for it into a reſolution to deſtroy it: this will abundantly appear from the following facts.

Charging the income of the *ſinking fund* with the payment of the intereſt of new loans, is an encroachment upon it, no leſs ſubverſive of its efficacy, than depriving it of groſs ſums; there being no difference between taking from it the annual intereſt of a ſum, and that ſum itſelf. Between the years 1727 and 1732 ſeveral encroachments of this kind had been made upon it; but, being of a leſs obvious nature, they paſſed without meeting with any particular oppoſition. The finiſhing blow was given it in the year 1733. In that year, in order to keep the land-tax at one ſhilling in the pound, as it had been the year before, it was neceſſary either to borrow half a million for the current ſervice, or to take this ſum from the *ſinking fund*. The laſt method was choſen, and propoſed by ſir Robert Walpole to the houſe of commons. Long and warm debates enſued. A propoſal to *alienate*, in a time of profound peace, a *fund* which the law had made ſacred, and the alienation of which *no poſſible exigence of public affairs* could juſtify, only for the ſake of keeping the land-tax for one year at one ſhilling in the pound, juſtly kindled the indignation of the patriotic party. They urged the prohibition of the law, the faith of parliament, and the ſecurity of the kingdom. The propoſer of the alienation was reminded of his inconſiſtency and treachery, in endeavouring to beat down that very monument of glory which he had boaſted of having erected for himſelf; and ſir John Barnard warned him, that he was drawing upon himſelf the curſes of poſterity. But all arguments were vain. The miniſtry pleaded that the landed intereſt wanted eaſe; that there was no occaſion for being in a hurry to pay the national debt; and that the circumſtances of the kingdom had altered ſo much ſince the eſtabliſhment of the *ſinking fund*, that the competition then among the public creditors was, not who ſhould be firſt, but who ſhould be laſt paid. Thus argued, among others, ſir Robert Walpole. His reaſons prevailed; and the houſe of commons, not uſed to refuſe him any thing, conſented.

The practice of alienating the *ſinking fund* having been thus begun, went on of courſe. In the next year, or 1734, 1,200,000*l.* was taken from it. In 1735, and 1736, it was anticipated and mortgaged.

Thus expired, after an exiſtence of a few years, the *ſinking fund*; that ſacred bleſſing (as it was once thought) and the nation's only hope. Could it have eſcaped, it would long before this time have eaſed Britain of all its debts, and left it a ſafe and happy country.

In order to obtain a juſter ſenſe of this, let us here compare what it would have done had it never been miſapplied, with what it has done.

Though the act that eſtabliſhed it was paſſed, as already ſaid, in 1716, it did not begin its operations till 1719, when three quarters of a million in old exchequer bills were paid off with it. The intermediate time had been employed in laying the foundations of this *fund*, and providing an income for it, by a general reduction of the public debts, from an intereſt of ſix per cent. and other higher intereſts, to five per cent. What made this reduction then practicable was a rapid fall of the intereſt of money, which begun (in conſequence of an increaſe of trade producing an influx of money) a little before the acceſſion. The legal intereſt of money was reduced in 1714, from ſix to five per cent. and the means uſed by government for accompliſhing this reduction were, firſt, the addition (at Michaelmas 1717) of the intereſt of ſome debts bearing five per cent. to the principal, in order to make uſe of the produce of the taxes which ſhould have paid the intereſt, in diſcharging the bankers debt and ſome other debts bearing ſix per cent.

Secondly, loans of five per cent. obtained chiefly from the Bank, and the South-ſea company, to pay off ſuch of the public creditors as did not chuſe to accept a lower intereſt than ſix per cent.

After this reduction, the three *funds*, before deſcribed, produced a ſurplus of above half a million per annum. In 1727 this ſurplus was increaſed to 959,103*l.* and in 1733 (the year when the practice of alienating it began) it had been increaſed ſo much by the redemptions made with it, and by a ſecond reduction of intereſt in 1727 from five to four per cent. that its medium for five years had been 1,212,000*l.* per annum. Had it, from the year 1732, been allowed to increaſe beyond this (except from the intereſt of debts paid by it), and been applied for the firſt twenty-five years to the payment of debts bearing four per cent. intereſt, and afterwards to the payment of debts bearing three per cent. it would in the preſent year (1779) have completed the redemption of one

hundred

hundred and forty-nine millions of debt, leaving the public, during this whole period, in poſſeſſion of all the ſurpluſſes which have ariſen in the revenue beyond 1,212,000l. except thoſe produced by redemptions. It is not poſſible to conceive the beneficial effects with which this would have been attended, or the vigour which would have been all along given to public credit by ſuch a *fund*, and by the proſpect it would have given of the total annihilation in this year of almoſt all the public debts, and the diſengagement of taxes bringing in above five millions per ann. to be either aboliſhed, or ſhould a war prove neceſſary) to be continued a few years longer, for carrying it on without making any addition to the public burdens. No perſon who duly attends to this, and wiſhes well to England, can avoid execrating the policy which firſt produced, and has ſince continued, the alienation of the *ſinking fund*, and converted an expedient for ſaving the kingdom, into a ſupply for extravagance and a ſupport of corruption and deſpotiſm. This, however, is a policy which it may be expected men in power will always uſe when they can; for few of them have ever ſhewn themſelves ſuperior to the temptations of power, or virtuous enough to avoid uſing all means to ſtrengthen and extend it.

Many ſchemes of different kinds have been formed for paying the public debts; and certain it is, that nothing can be of more importance. But the nature of things doth not admit of any method of doing this ſo expeditiouſly and effectually as an unalienable *ſinking fund*; for in ſuch a *fund* (it has been ſhewn) money is improved at compound intereſt, and therefore in the moſt perfect manner. The writers, therefore, who have employed themſelves in contriving ſuch ſchemes might have ſpared their labour. The beſt of all ſchemes has been long known and eſtabliſhed, and received all the weight and efficiency which could be given it by the moſt ſolemn acts of legiſlature. But no legiſlature can give ſecurity againſt itſelf. No parliament can do any thing which it may not undo, eſpecially if under any undue influence.

We have now ſeen what the *ſinking fund* would have done, had it ſuited the views of the Britiſh miniſtry in 1733 to ſuffer it to go on with its operations. Let us next compare this with what it has done.

In 1737 and 1738, a million of the ſtock of Bank annuities and two millions of the ſtock of South-ſea annuities were redeemed with it. For twelve years after 1738, it was wholly applied to the current expences of every year. In 1749, the intereſt of near fifty-eight millions of the public debts was reduced from four to three one half per cent, intereſt for ſeven years, and afterwards to three per cent. for ever; and by this third reduction, an addition was made to the *ſinking fund* of near 600,000l. per ann. But notwithſtanding this addition, no more than three millions of the public debts were redeemed by it, during the interval of peace between the years 1748 and 1756.

By an act of the 25th of Geo. II. 1752, a change was made in the *ſinking fund*, which it is neceſſary to mention.

Before this act the *ſinking fund* conſiſted only of the clear ſurpluſſes of the aggregate, the general, and the South-ſea company's *funds*. By the war, which began in 1740, there was an addition made to the public debts of near thirty-two millions. This occaſioned a great increaſe of taxes; and the practice was, whenever any new tax produced leſs than the intereſt with which it was charged, to make good the deficiency out of the *ſinking fund*, and afterwards to replace the ſum taken from it out of the ſupplies for the following year. But whenever a tax produced more than the charge upon it, the overplus, inſtead of being carried to the *ſinking fund*, was made a part of the ſupplies for the year. By the act juſt mentioned, all the new taxes, together with all the annuities to the payment of which they had been appropriated, were ordered to be carried into the *ſinking fund*, and formed into one general account. Moſt of the new taxes having proved deficient, this *fund* at firſt loſt more than it gained by the change. But the loſs was afterwards more than made up; firſt, by the ſaving which was produced by the reduction of intereſt from three one half per cent. to three per cent. in 1757; and, ſecondly, by the addition, in the ſame year, of the ſalt-duties to this *fund*, after they had completed the redemption of a million with which they had been charged in 1745.

The war which began in 1756, added ſeventy-one millions and a half to the public debts. This produced a new increaſe of taxes, which (in conformity to the conſolidating act juſt mentioned) have been brought to the general *ſinking fund* account, together with the annuities or intereſts with the payment of which they are charged. And it is now the conſtant practice, whenever a new *fund* or tax is created for paying the intereſt of a loan, to carry both into the *ſinking fund*; in conſequence of which this *fund* gains when the tax happens to produce more, but loſes when it produces leſs than the intereſt which it has been given to pay. The *ſinking fund*, therefore, which, before the conſolidating act, conſiſted only of the ſurpluſſes of the aggregate, general, and South-ſea company's *funds*, conſiſts now of the clear ſurplus of all the appropriated taxes. There is but one tax excepted; and that is, the additional tax upon houſes and windows, granted in 1758 towards paying the intereſt of four millions and a half then borrowed. This tax has never been made a part of the *ſinking fund*; and, having always proved deficient to the amount of about 45,000l. per ann. the deficiency is conſtantly made good by the *ſinking fund*, and afterwards replaced from the ſupplies.

Before the laſt reduction of the intereſt of the public debts, the *ſinking fund*, having ſuffered greatly from various encroachments upon it, produced little more than a million per ann. But after this reduction, and its *increaſe* by the addition of the ſalt-duties, it produced near two millions per ann. In 1764 it produced at Michelmas, after making good deficiencies, 2,105,000l. nearly. For five years after 1764, its average produce, reckoned to Chriſtmas in every year, was 2,234,780l. For five years, ended in 1774, its average produce was 2,615,719l. In 1775, it produced 2,917,869l. In 1776, 3,166,517l. In 1777 it was charged with an annuity of 100,000l. per ann. to the civil liſt; and, after paying this annuity and half a year's intereſt of five millions borrowed in that year, it produced nearly 2,700,000l. In 1778 it was taken at three millions; but did not produce, after paying the ſaid annuity, and making good the intereſts of the new loans in 1777 and 1778, more than two.

It appears from this detail, that ſince the peace in 1763 the income of the *ſinking fund* has increaſed conſiderably. The cauſes of this have been partly the falling in of life-annuities, and the greater productiveneſs of the taxes occaſioned by the increaſe of luxury. But the principal cauſe has been the falling in of the intereſt of about ten millions and a half of the public debts, which had been diſcharged during the twelve years of peace between 1763 and 1775. This diminution of the public debts has been made, not by the *ſinking fund*, but by a contribution from the Eaſt-India company of 400,000l. per ann. begun in 1768, and continued for five years; by the profits of ten lotteries; by the compoſition for maintaining French priſoners; ſale of French prizes taken before the declaration of war in 1756; and other extraordinary receipts, amounting in all to above eight millions. This *fund*, therefore, did not pay off more than two millions and a half, the reſt of its produce having been employed in bearing the expences of the peace eſtabliſhment, which, during this period, was nearly double to what it had been in any former period.

To the ſum juſt mentioned, add three millions paid off in the peace between 1748 and 1756, and three millions paid off in 1736 and 1737, and it will appear that the whole amount of the public debts paid off by the *ſinking fund*, ſince its firſt alienation in 1733, is only eight millions and a half; whereas it has been ſhewn, that had only 1,212,000l. per ann. of it been applied inviolably to the redemption of the public debts, one hundred and forty-nine millions would have been paid, and conſequently the nation extricated and ſaved.

It has been ſaid, that when money is wanted for defraying public expences, it makes no difference whether it is obtained by diverting the *ſinking fund* or by a new loan. There cannot be a worſe fallacy than this. Money in a *ſinking fund*, if never alienated, is improved at compound intereſt; but, when procured by a loan, bears only ſimple intereſt. A nation, therefore, whenever it applies the income of ſuch a *fund* to current expences rather than the redemption of its debts, chuſes to loſe the benefit of compound intereſt in order to avoid paying ſimple intereſt; and the loſs in this caſe is equal to the difference between the increaſe of money at compound and ſimple intereſt. The following calculation will ſhew what this difference is.

One penny put out at our Saviour's birth to five per cent. compound intereſt, would, before the preſent year 1779, have increaſed to a greater ſum than would be contained in a hundred and fifty millions of earths, all ſolid gold. But, if put out to ſimple intereſt, it would, in the ſame time, have amounted to no more than ſeven ſhillings and ſix pence. All governments that alienate *funds* deſtined for reimburſements, chuſe to improve money in the laſt rather than the firſt of theſe ways. See, on the ſubject of this article, Dr. Price's Appeal to the Public on the Subject of the National Debt. Alſo his Obſervations on Reverſionary Payments, &c. chap. iii. And additional Obſervations on Civil Liberty, part iii.

FUNDA-

FUNDAMENT, the anus or aperture, through which an animal voids his excrements.

FUNDAMENTAL, fomething that ſerves as a baſe, reſt, ſupport, or foundation, for any thing.

The apoſtles creed contains the *fundamental* points of religion.

The Salic law is the *fundamental* law of the polity of France.

FUNDAMENTAL, in *Muſic*, denotes the principal note of a ſong or compoſition, to which all the reſt are in ſome meaſure adapted, and by which they are ſwayed; called alſo the KEY of the ſong.

FUNDAMENTAL *baſs*, is that which is formed only of the *fundamental* ſounds of HARMONY, in ſuch a manner, that in every concord it leads us to perceive the true *fundamental* ſound of that concord; whence it appears that it can have no other contexture than that of the *fundamental* ſucceſſion of the harmony. The *fundamental* ſounds are the octave above the principal ſound, the twelfth and the ſeventeenth major above the ſame ſound. In order to underſtand the nature of the *fundamental* baſs, it is neceſſary to know, that every concord, though compoſed of many ſounds, has only one ſound which is *fundamental*, viz. that which has produced that concord, and which ſerves for its baſs. But the baſs, which prevails below all the other parts, does not always expreſs the *fundamental* ſounds of the concords; for of all the ſounds of a concord, we are at liberty to tranſfer to the baſs that which we think preferable, with regard to the movement of this baſs, the pleaſantneſs of the tune, or the expreſſion. In this caſe, the true *fundamental* ſound, inſtead of being in its natural place, which is the baſs, is tranſferred to the other parts, or not expreſſed at all; and ſuch a concord is called a reverſed concord. See REVERSING.

In reality, there is no difference between a reverſed concord and the direct concord by which it is produced; for the ſounds are always the ſame: but theſe ſounds forming different combinations, the combinations reſulting from them have for a long while been conſidered as ſo many *fundamental* concords, and diſtinguiſhed by different names. M. Rameau has ſhewn, in his Traité de l'Harmonie, that many of theſe pretended concords are only different modifications and alterations of a ſingle concord: thus, the concord of the ſixth is only a perfect concord, the third of which is tranſferred to the baſs; in which, by introducing the fifth, we ſhall have another concord of the ſixth and fourth. Here, then, are three combinations of a concord which has but three ſounds; thoſe that have four are capable of four combinations; for each of the ſounds may be tranſferred to the baſs. But if below this another baſs be introduced, which, in all the combinations of the ſame concord, always affords the *fundamental* ſound, it is evident that the number of the conſonant concords is reduced to three, and that of the diſſonant to four; to which, if we add all the concords by SUPPOSITION, which may likewiſe be reduced to the ſame *fundamentals*, we ſhall find harmony ſimplified to a degree which could never have been expected, conſidering the ſtate of confuſion in which M. Rameau found the rules relating to this part of muſic. It is certainly, as this author obſerves, very aſtoniſhing, that perſons have been able to advance the art to its preſent pitch of perfection, without knowing its foundation, and to propoſe all its rules with ſuch exactneſs, without having diſcovered the principles on which they depend. The movement of the *fundamental* baſs is regulated by the laws of harmonic ſucceſſion, in ſuch a manner, that if this baſs deviates from the order which is preſcribed, there is a fault in the harmony. With ſkill to regulate and obſerve the connection between the ſeveral ſounds that are united together, are the two moſt important rules relating to the *fundamental* baſs; and the principal mechanical rule which is ſuggeſted by it, is to let the *fundamental* baſs proceed only by conſonant intervals, except when the cadence is broken; i. e. when the *fundamental* baſs, inſtead of aſcending from the fourth, after a concord of the ſeventh, as in a perfect cadence, aſcends only by one degree; or after a concord of the ſeventh diminiſhed, in which caſe it riſes diatonically. As for the diatonic deſcent, this movement is not allowed in the *fundamental* baſs, or at moſt only in the caſe of two perfect concords ſeparated by a reſt or pauſe, either expreſſed or underſtood. This rule admits no other exception. M. Rameau, indeed, has made the *fundamental* baſs deſcend diatonically, for particular reaſons, in the concords of the ſeventh.

The *fundamental* baſs, whenever it is juſtly formed, conſiſts either of perfect concords with conſonant movements, without which theſe concords could have no proper connection, or diſſonant concords in the *acts of cadence*, which always reſult from two *fundamental* ſounds, one of which precedes, and the other terminates the cadence. In every other caſe, the diſſonance can neither be well placed, nor rightly prepared. Hence it follows, that the *fundamental* baſs can never proceed but in one of theſe three ways: 1. By aſcending or deſcending from the third or from the fifth; 2. From the fourth or the fifth; or, 3. By aſcending diatonically, by means of the diſſonance that forms the connection, or by particular licence, above the perfect concord. Every other movement of the *fundamental* baſs is faulty.

Although the *fundamental* baſs ought, in general, to be below the *thorough-bass*, there are, however, caſes in which the latter is below the former; ſuch are thoſe of *concords by* SUPPOSITION, ſo called, becauſe the thorough-baſs ſuppoſes below the concord a new ſound which does not belong to that concord, which exceeds its limits, and is, therefore, below the *fundamental* baſs.

The *fundamental* baſs, the ſole intention of which is to ſerve as a proof or teſt of the harmony, is ſuppreſſed in the execution, where it would have a very bad effect; producing, at leaſt, a very tedious monotony by the frequent returns of the ſame concord, which are more agreeably diſguiſed and varied, by its different combinations, in the thorough-baſs. It may be added, in general, that the indiſpenſible rules of the *fundamental* baſs may be reduced to the three following.

1. There ought always to be at leaſt a common ſound in the harmony of two ſucceſſive *fundamental* ſounds. 2. In every DOMINANT, the diſſonance ought to be ſo managed, that the dominant may not become TONIC. 3. Every dominant ought to deſcend from the fifth, and every SUB-*dominant* ought to aſcend from the fifth.

But beſides it may be obſerved, that the *fundamental* baſs is ſometimes irregular; and in the number of its irregularities we may reckon the concords of the ſeventh diminiſhed, and the broken cadences. The thorough-baſs is only the *fundamental* baſs reverſed for the eaſe of melody; ſo that when the *fundamental* baſs is compoſed, the thorough-baſs may be had by REVERSING the concords. E. *gr.* This *fundamental* baſs of one ſound, *ut ſol ut ſol ut*, may give this more melodious thorough-baſs *ut ſi ut rè mi fa mi*. The thorough baſs muſt be made conformable to the *fundamental*, only when it approaches cadences, or is terminated there. The thorough-baſs admits alſo concords by SUPPOSITION. Every note in the thorough-baſs, which bears the concord of the falſe FIFTH, ought to riſe diatonically; and every note which bears the concord of the TRITONE ought to deſcend diatonically. The knowledge of the *fundamental* baſs, or the rule for finding the *fundamental* baſs of a given tune, depends much upon that of the MODE or MODULATION. Encyclopedie, art. *Fondamental* Baſse.

FUNDAMENTAL *concords* are of three kinds; viz. the perfect concord, the concord of the ſixth, and the concord of the ſeventh. The firſt or perfect concord, is greater or leſs, according as the THIRD is greater or leſs. The ſecond is of three ſorts: in the two firſt ſorts, the SIXTH is always greater, and the third greater or leſs, as the mode is greater or leſs. Theſe two concords differ only by their third. Between theſe two there is another concord, which on many occaſions produces a very good effect, and is particularly uſed by the Italians; whence it is called the concord of the ſuperfluous ſixth, or of the Italian ſixth. It is compoſed of a greater third, or ſuperfluous fourth, or TRITONE, and a greater third, as *fa la ſi rè*. There are ſeveral kinds of the *fundamental* SEVENTH: the firſt is formed of a greater third, and two leſſer fifths, as *ſol ſi rè fa*; the ſecond is formed of a leſſer third, a greater third, and a leſſer third, as *rè fa la ut*; the third is formed of two leſſer thirds, and a greater third, as *ſi rè fa la*; the fourth is formed of one greater third, one leſſer, and one greater, as *ut mi ſol ſi*; the fifth is called the concord of the diminiſhed ſeventh, and formed of three leſſer thirds, *ſi re fa ſol*. Encyclopedie, art. *Accords* FONDAMENTAUX.

FUNDAMENTO, in the *Italian Muſic*, is in general every part that plays or ſings the baſs; but the thorough-baſs is more particularly ſo called, becauſe it is the baſis or foundation of all harmony.

FUNDUCLÆ, an Egyptian coin, a ſort of ſequin, of the value of a hundred and forty-ſix medines. Pococke's Egypt, p. 175.

FUNDULUS, in *Ichthyology*, a name uſed by many for the ſmall fiſh, called by others COBITIS, and by the generality of people in England, the LOACH.

FUNDULUS is uſed alſo by Schoneveldt, and ſome others, to expreſs the common gudgeon. The confuſion of calling two fiſh by the ſame name, which is peculiarly appropriated to neither, is very evident in this and numerous other inſtances; but it is always to be avoided by uſing expreſſive and genuine names. Thus even the word gobio, the common name of the gudgeon, confounds

founds that fish with another very different genus; and Artedi is greatly to be applauded, who has found that our common gudgeon is no peculiar genus of fish at all, but is a species of the cyprinus. As fuch he has given it the proper specific name of the five inch spotted cyprinus, with the lower jaw shorter than the upper, and with two cirri or beards at the mouth; under this name the species is always to be known at fight, and can never be confounded with any other genus.

FUNERAL, the ceremonies performed at an interment; or the laft offices paid to the deceafed. See BURIAL.

The word is formed of the Latin *funus*; and that of *funalia*, on account of the torches (which were *funes, ceræ circumdati*) ufed in the *funerals* of the Romans; though others derive *funus* from the Greek φονος, *death*, or *flaughter*.

The firft perfons who feem to have paid any particular refpect to their dead were the Egyptians, who erected monuments for tranfmitting the remembrance of their virtues to future ages. See PYRAMID.

Whenever a perfon died among the Egyptians, his parents and friends put on mournful habits, and abftained from all banquets and entertainments. This MOURNING lafted from forty to feventy days, during which time they embalmed the body. See EMBALMING.

When this ceremony was finifhed, the embalmed body was reftored to the parents, who placed it in a kind of open chefl, which was preferved either in their houfes, or in the fepulchres of their anceftors. Before the dead were allowed to be depofited in the tomb, they underwent a folemn judgment, which extended even to their kings; and if the iffue of the judgment proved unfavourable, they were deprived of the rites of burial; and this cuftom feems to have been practifed among the Ifraelites; for we read, that their wicked kings were not interred in the fepulchres of their anceftors.

The *funeral* rites among the ancient Romans were very numerous. The deceafed was kept feven days: and every day waflied with hot water, and fometimes with oil, that, in cafe he were only in a flumber, he might be thus waked; and every now and then his friends meeting, made a horrible outcry or fhout, with the fame view; which laft action they called *conclamatio*.

The third conclamation was on the feventh day; when, if no figns of life appeared, the defunct was dreffed and embalmed by the pollinctores; placed in a bed near the door, with his face and heels towards the ftreet; and the outfide of the gate, if the deceafed were of condition, was garnifhed with cypreis boughs.

In the courfe of thefe feven days, an altar was raifed near his bed-fide, called *ara*; on which his friends every day offered incenfe; and the libitinarii provided things for the *funeral*.

On the feventh day a crier was fent about the city to invite the people to the folemnization of the *funeral* in thefe words: *Exequias* L. Tit. L. *filii; quibus eft commodum ire, jam tempus eft. Olius* (i. e. ille) *ex ædibus efertur*.

The people being aflembled, the laft conclamation ended, and the bed was covered with purple; a trumpeter marched forth, followed by old women, called *præficæ*, finging fongs in praife of the deceafed; and laftly, the bed followed, borne by the next relations. And if the perfon were of quality and office, the waxen images of all his predeceffors were carried before him on poles.

The bed was followed by his children, kindred, &c. *ater is*, or in mourning: from which act of following the corpfe, thefe *funeral* rites were called *exequiæ*.

The body thus brought to the roftra, the next of kin *laudabat defunctum pro roftris*, made a *funeral* oration in his praife, and that of his anceftors.

This done, the body was carried to the *pyra*, or *funeral* pile, and there burnt: his friends firft cutting off a finger, to be buried with a fecond folemnity.

The body confumed, the afhes were gathered, and the prieft fprinkling the company thrice with clean water, the eldeft of the *præficæ* crying aloud, *ilicet*, difmiffed the people, who took their leave of the deceafed in this form, *Vale, vale, vale: nos te ordine quo natura permiferit feqnemur*.

The afhes, inclofed in an urn, were laid in the fepulchre, or tomb. The firft Romans did not burn their dead, but interred them, as we do. Pliny, lib. vii. cap. 54, aflures us, that the cuftom of burning was not introduced till after they had learnt that their enemies dug up, and expofed, the bodies of their foldiers buried in remote countries. And yet Plutarch, in his Life of Numa, obferves, that Noma was buried; as having expreffly forbid them by his teftament to burn him: this fhews that the Romans had practifed burning before his time.

This cuftom of burning the dead, fo religioufly obferved by the Greeks and Romans, was held in abhorrence by feveral other nations.

Herodotus relates, that the Perfians detefted it, as holding fire to be a god. The Egyptians declined to burn their dead, as taking fire for an inanimate beaft, and judging it impiety to commit the bodies of the deceafed to be devoured by beafts. The cuftom of burning among the Romans ceafed under the empire of the Antonines. See BURNING and MOURNING.

In the Romifh church, when a perfon is dead, they waflh the body, and put a crucifix in its hand. At its feet ftands a veffel of holy water, that they who come in may fprinkle both themfelves and the deceafed. In the mean time fome prieft ftands by the corpfe, and prays for the deceafed till it is laid in the earth. In the *funeral* proceffion the exorcift walks firft, carrying the holy water; next the crofs-bearer, afterwards the reft of the clergy, and laft of all the officiating prieft. They fing the *miferere*, and fome of the Pfalms; and at the end of each Pfalm, a *requiem*. We learn from Alet's ritual, that the faces of deceafed laymen muft be turned towards the altar, when they are placed in the church; and thofe of the clergy towards the people. The corpfe is placed in the church, furrounded with lighted tapers; after the office for the dead, mafs is faid; then the officiating prieft fprinkles the corpfe thrice with holy water, and as often throws incenfe on it. The body being laid in the grave, the friends and relations fprinkle the grave with holy water.

FUNERAL *charges*, are not allowable againft a creditor, except for the coffin, ringing the bell, parfon, clerk, and bearer's fees; but not for the pall and ornaments. See DEBT.

FUNERAL *eclumn*. See *Funeral* COLUMN.

FUNERAL *games, ludi funebres*, were a part of the ceremony of the ancient *funerals*.

They confifted chiefly in proceffions, and fometimes in mortal combats of gladiators around the *funeral* pile.

The cuftom was very ancient; though it had not always been the fame. At firft, they cut the throats of a number of captives before the pyra, as victims to appeafe the manes of the deceafed. This Achilles does in Homer, Iliad φ, at the *funeral* of Patroclus; and Æneas, in Virgil, lib. xi. at that of Pallas, fon of Evander. Cæfar, in his Commentaries, lib. viii. relates, that the Gauls alfo did the like.

But at length it appeared barbarous, thus to butcher men; and therefore to fave the horror of the fpectacle, yet without the dead's lofing any thing thereby, they made the poor captives fight and kill one another, only faving fome few of fuch as came off victors.

This cuftom was borrowed from the Greeks by the Romans; among whom the cruel diverfion was called *munus*.

The firft who introduced it at Rome was Junius Brutus, at the obfequies of his father; or, according to others, Ap. Claudius, and M. Fulvius, during their confulate.

The like horrible combats were alfo occafionally exhibited by the magiftrates; and fometimes they were added to the theatrical pieces.

The emperor Claudius decreed, that whereas thefe accurfed games were till then frequent and arbitrary; it fhould be the practice for the future only to perform them regularly every year at the expence of the ftate; and that the ædiles fhould have the care and direction thereof. But he conceived a horror for them himfelf, and foon after abolifhed them; though it was ftill allowed particular perfons to have them, provided they were worth forty thoufand feflerces per annum. They were not finally abolifhed before the time of Theodoric king of the Goths, at the end of the fifth century.

FUNERAL *honours*. See HONOURS.

FUNERAL *oration*, or *fermon*, a difcourfe pronounced in praife of a perfon deceafed, at the ceremony of his *funeral*.

The cuftom of making *funeral* orations is very ancient: The Romans had it of a long ftanding; and it was always one of the neareft relations that made the harangue. Auguftus did the office to his grandmother Julia, when only twelve years of age. Suet. Aug. cap. 8. And we have divers parallel inftances.

The cuftom feems to have begun with the republic; at leaft, the firft *funeral* oration we read of, was that of Brutus, who expelled the kings, and was the firft conful; who, having been killed in a battle againft the Hetururians, *laudabatur pro roftris*, was praifed in the forum by Valerius Publicola his colleague.

Indeed, fome authors will have the practice more ancient. They maintain it to have been in ufe among the Greeks; and that Solon, who, according to Aulus Gellius, gave laws to the Athenians, in the time when the elder Tarquin reigned in Rome, was the firft author thereof; fomething like which, it feems, the orator Anaximenes has left in writing. See Polydore Virgil De Invent. Rer. lib. iii. cap. 10.

FUNGIFER *lapis*, the *muſhroom-bearing ſtone*, a name given by authors to a coarſe ſtone found in Italy, and many other places lying near the ſurface of the earth, which they ſay will at any time produce *muſhrooms*, on being moiſtened with warm water.

FUNGITÆ, in *Natural Hiſtory*, a name given by authors to a ſpecies of ſea-coral, often found adhering to ſea-ſhells, or to the larger corals in its recent ſtate, and very often found alſo foſſile, or buried at great depths in the earth; they are uſually immerged in ſtone, and ſometimes in clay. The more frequent of theſe are of a conic ſhape; ſometimes they are flatted and diſcoide, and uſually ſtriated longitudinally; they ſometimes are found in their foſſile ſtate adhering to ſhells or corals, but more uſually ſeparate. To this and ſome other bodies of this kind, Mr. Lloyd has given the name *columella*; to one of them that of *branchiale*, from its reſembling the gills of a fiſh; and to another, that of *undulage*, from its undulated figures.

FUNGOIDES, *baſtard-muſhroom*, in *Botany*, the name of a genus of plants, the characters of which are the ſame with thoſe of the fungus, from which it differs only in being of a hollowed form, reſembling a cup or empty open box. See CLAVARIA, ELVELA, and PEZIZA.

FUNGOUS *fleſh*, is a ſpongeous excreſcence, or (as we popularly call it) *proud fleſh*, frequently growing on the lips of wounds, ulcers, &c.

The *ſarcocele* is the effect of a ſort of *fungous* fleſh.

In ulcers, Wiſeman obſerves, there frequently ariſes a ſpongeous, or *fungous* fleſh, either from the too great afflux of humours, or through the ſurgeon's unſkilfulneſs. It muſt be ſuppreſſed, or taken off by drying medicines, or even by cauſtics; as lapis tutiæ, burnt alum, precipitate of mercury, Roman vitriol, &c.

FUNGOUS *tumors*. See TUMOR.

FUNGUS, in *Natural Hiſtory*. See MUSHROOM.

FUNGUS, in *Surgery*, a fleſhy TUMOR, or excreſcence, very ſpongeous, ſoft, and pale; ariſing on the membranes, tendons, and other nervous parts, in conſequence of ulcers, wounds, contuſions, and ſtrains.

Fungoſes are frequently formed on the meninges, or membranes of the brain, in wounds of the head when not well covered, or defended from the external air: they are alſo frequent about the joints; which laſt grow very inſenſibly.

But where the ſkin is open, finding more room, they grow to a prodigious degree in a very little time, aſſuming the form of a muſhroom, or *fungus*.

There are alſo *fungoſes* of the anus, and uterus. They are all ſuppoſed to proceed from a retention and depravation of the nutritious juice.

The *fungus* is a general kind of excreſcence, whereof there are divers particular ſpecies: as the *ficus*, the *ſarcoma*, *condyloma*, &c.

FUNGUS *of the brain*. Mr. Queſney aſſures us, that ſpirits are not ſo proper for preventing the growth of *fungoſes* from the brain, as balſam florivanti, or oleum terebinth. Mem. de l'Acad. de Chirurg. tom. i.

FUNGUS, in *Mineralogy*, a name given by Dr. Liſter, to a blackiſh bituminous ſubſtance, found in ſome of the mines of Derbyſhire. It adheres to the ſides of the fiſſures of rocks, and lies in ſeams of the ſtrata. It is of a blackiſh colour and fatty ſubſtance, which never dries in the air, but always remains as moiſt as when taken out of the mine. Some maſſes of it are ſoft and like a jelly, others are hard and firm, and in theſe there are ſeveral lumps of pure bitumen in many parts. This is inflammable like reſin. It is light, but breaks finer, and ſhines like good aloes when freſh broken, but that it is a little darker coloured, and has ſome tinge of purple in it. In ſome pieces the purple is wanting, and there is a green in the place of it. On being diſtilled, it yields firſt a limpid and inſipid water, then a whiſh water of a ſharp taſte, and finally a yellow and clear oil, much reſembling oil of amber, but the proceſs affords no volatile ſalt in the neck of the receiver, in which it differs from AMBER when treated in the ſame manner. Phil. Tranſ. N° 6.

FUNGUS *oculi*, a name given by ſome of the writers on the diſeaſes of horſes to a diſtemper of the eye, to which that animal alone is ſubject. The firſt author who has communicated an obſervation of this diſorder to the world is Dr. Lower, in the Philoſophical Tranſactions. He obſerves, that horſes alone are ſubject to it, and calls it a ſpungy excreſcence of the uvea; it is commonly of a dark muſk-colour, and grows out of the edge of the uvea; and though of little conſequence in its firſt ſtages, yet if it grows very large, or if the number of the *fungoſes* increaſe, it weakens and obſtructs the creature's ſight, and ſometimes wholly takes it away. The uvea is a muſcular part, and its chief uſe is to dilate or contract itſelf in a proper manner for the admiſſion of objects with as much light as the eye can bear, ſo that the brighter the light is, to which the eye is expoſed, the more this membrane is contracted into a narrow compaſs, and the more dark the place is, the more the opening is dilated. This ſudden change, and the office of this part, may be more conveniently ſeen in the eye of a cat, than in that of any other animal, but it is the ſame in all, in a greater or leſs degree. If the edge of this coat be loaded with a very large excreſcence of this kind, or if ſeveral, though ſmaller, grow all round it, it muſt neceſſarily happen, that the pupil, or ſight, is very much if not totally obſtructed, and the animal ſees very little, or not at all. The horſes of this kind are very ill furniſhed for ſeeing in the ſunſhine, but do very well in dark days, or in the duſk of the morning or evening, when the diſeaſe is not too violent. It is obſervable, that when theſe *fungoſes* grow in the eyes of young horſes, they become much ſmaller, when they are taken to dry meat in the ſtable, and increaſe again when they are turned out to graſs. Whether this be owing to the difference of dry and moiſt food, is not eaſy to determine, but it is moſt probably owing to the difference of paſture: the horſe at graſs, being obliged to carry its head much lower than thoſe which feed in the ſtable. Thoſe *fungoſes* that are fixed on the upper part of the uvea, are apt to grow the largeſt, and to hinder the ſight moſt; and thoſe which grow in the middle of the uvea, hinder the ſight more by diſtracting the object, than thoſe which grow in either corner or angle of it. The cure is not eaſy; all that can be attempted muſt be by dry diet, and attenuating medicines; and a palliative remedy may be the hanging ſomething over to ſhade the eye, and keeping it from being expoſed nakedly to the ſun, the conſequence of which will be, that the pupil will not be ſo cloſely contracted, and conſequently the light not ſo much obſtructed. Phil. Tranſ. N° 32.

FUNICULUS *umbilicalis*. See UMBILICALIS.

FUNNEL *of a chimney*, the ſhaft, or ſmalleſt part, of the chimney, from the waiſt upwards.

Palladio orders, that the *funnel* be raiſed three, four, or five, feet at leaſt, above the roof, that it may carry the ſmoke clear from the houſe into the air.

Care, too, is to be taken, as to the width; becauſe, if it be too wide, the wind will drive back the ſmoke into the room; and if too narrow, the ſmoke will not be able to make its way. Chamber-chimneys, therefore, are not to be made narrower than ten or eleven inches; nor broader than fifteen. See CHIMNEY.

FUNNEL *faſhioned flowers*. See *Infundibuliform* FLOWERS.

FUNNEL *polype*. See POLYPE.

FUR, in *Commerce*, &c. See FURR.

FURBISHER, a perſon who furbiſhes, or poliſhes arms, and gives them a brightneſs and luſtre.

In the general ſenſe of the word, it includes what we now call *armourers* and *ſword cutlers*; in a more reſtrained ſenſe, it is appropriated to thoſe who clean, and ſcour up old ſwords, guns, and halberts, and put them in order.

Among the officers of the Tower, there is a *furbiſher* of ſmall arms, another of ſwords; and the like there is in moſt other armories of England; or at St. James's, Windſor, Cheſter, Plymouth, Hull, and Berwick.

FURBISHING, the act of cleaning, ſcouring, and poliſhing, arms; as guns, piſtols, ſwords, &c.

The word is formed of the French *fourbiſſure*, which Hicks derives from *furbon*, which in the language of the ancient Franks ſignified to clean and poliſh: though M. Huet chooſes rather to derive the French *fourbir*, and *fourbiſſure*, from the Engliſh *furbiſh* and *furbiſhing*. Skinner obſerves, that ſome authors derive the Engliſh *furbiſh* from the Latin *furvus*, and *furvor*; but for his part, he rather derives it from the German *farb*, colour; and *furben*, to dye, or give a colour.

Furbiſhing is principally performed with emery.

FURCA, FORK, in *Antiquity*, a kind of puniſhment, or rather an inſtrument of puniſhment, among the Romans. The form of the Roman *furca* is very obſcurely deſcribed by the ancients, and much controverted by the moderns. All we know for certain is, that it was of wood, and reſembled a fork; whence it is called, in writers, *furca bicornis*, *bicornis ſudacula*, that is, *lignum duplex*, *bicornutum*, *geminum*; a double forked, or horned timber. Plautus, treating of the *furca*, ſays, it is originally the piece of timber wherewith the beam of the waggon is upheld; he adds, that it is the ſame with what the Greeks call *apoſtates*, and *ſtereigma*; and the *ſtereigma* is deſcribed, by Heſychius, as the forked piece of timber put under the yoke of the waggon.

From theſe accounts, Godwyn takes the *furca* to have been the beam of a waggon, to which the yokes are faſtened.

The puniſhment of the *furca* was of three kinds; the firſt, only *ignominious*, was when a maſter forced his ſervant, for ſmall offences, to carry a *furca*, or fork, on his ſhoul-

ders, about the city; confeſſing his fault, and warning others to beware of the like: whence ſuch ſervant come to be denominated *furciſer*.

The ſecond kind was *penal*; when the party, having the *furca* on his neck, was led about the circus, or other place, and whipped all the way.

The third was *capital*; the malefactor having his head faſtened to the *furca*, and ſo being whipped to death.

In after-times of the empire, when this ſort of puniſhment became interdicted, the form of the *furca* was changed, and made like our GIBBETS, or gallows. See CROSS, &c.

FURCA *& flagellum*, in our old writers, denotes the meaneſt of all ſervile tenures, when the bondman was at the diſpoſal of his lord for life and limb. *Iſte tenet in villenagio ad* furcam & flagellum *de domino ſuo, &c.*

FURCA *and foſſa*, in our ancient cuſtoms, i. e. gallows and pit, denoted a right, or juriſdiction, of puniſhing felons; viz. men with hanging, women with drowning.

FURCHE, in *Heraldry*, a croſs forked at the ends. See CROSS.

FURCULA, in *Anatomy*, the ſame with CLAVICULA.

FURFUR literally ſignifies BRAN; and is therefore uſed for the ſcales, ſcurf, or dandriff, which grow upon the ſkin; having ſome likeneſs thereto. See CUTICULA.

FURFURATION, the falling off of *furfures*, in combing, &c.

FURIA, in the *Italian Muſic*, is uſed for a very quick and ſtrong manner of ſinging or playing.

FURIAN *Law*, in *Roman Antiquity*, a teſtamentary law, ſo called from C. Furius, the tribune, by whoſe intereſt it was enacted. This law forbad any Roman citizen to leave by legacy above the value of one thouſand aſſes to any one perſon, and at the ſame time condemned the legatee to pay four times the ſum which was given him above what the law ſtipulated. See VOCONIAN *Law*.

FURIES, *Eumenides, Diræ*, in the *Heathen Theology*, and *Poetry*, were infernal deities, ſuppoſed to be the diſpenſers of the divine vengeance, the puniſhers of wicked actions both here and hereafter, and the inflictors of terrors, wars, and peſtilence.

The *Furies* were reputed the miniſters of Pluto, and the revengers of crimes. Strabo paints them clothed in long robes falling to their heels, but girt about the breaſt. They were three in number; TISIPHONE, MEGERA, and ALECTO.

The poets ſpeak of great numbers of *Furies*, ſome of whom were employed in tormenting criminals in Tartarus, and others wandering over the earth to tempt, or to puniſh the wicked here. Thus Virgil ſpeaks of the

—agmina ſæva ſororum. Æn. vi. ver. 571.

But the three, above named, were ſuppoſed to exceed all the reſt in cruelty and malice, and the power of doing miſchief, and are called, by way of eminence, *the Furies*, and ſometimes the *Diræ*, a name peculiar to theſe three. They were three ſiſters, and born at one birth of the goddeſs of night.

Patin, Spanheim, &c. will have it to be thoſe which we ſee on a medal of the emperor Philip, ſtruck at Antioch, on whoſe reverſe are repreſented three women dreſſed as above mentioned, and armed with a key, and burning torches, poniards, and ſerpents.

Struvius, Antiq. Rom. Synt. cap. i. p. 182, adds, that the three *Furies* may probably be no other than the triple Hecate, whom the ancients believed to purſue and torment the wicked in hell, on earth, and in heaven.

Some of the poets add a fourth *Fury* called *Liſſa*, a Greek word, ſignifying madneſs, or rage.

They repreſent the *Furies* as old, ſqualid, and meagre, with pale cheeks having a kind of feveriſh fluſh on them, with eyes inflamed, their heads twiſted round with ſnakes, and furniſhed with whips and burning torches in their hands, to puniſh the guilty.

The aſſodil was ſacred to the *Furies*, and ſuch as offered ſacrifices to them were crowned therewith. This we learn from Euſtathius, on the firſt book of the Iliad, p. 87.

Theſe *Furies* were alſo called *Pœnæ*, Ποιναι, on account of the puniſhments they inflicted on criminals; as their denomination *Furies* aroſe from the rage and madneſs which they threw into the conſcience. Voſſ. De Idolol. lib. viii. cap. 18.

The Greeks called them *Eumenides*; the origin of which name is much controverted among the learned. The etymology that ſeems beſt authorized, derives it from ευμενες, *gentle, mild*; which was applied to them on occaſion of Oreſtes's being abſolved of the murder committed by him on the perſon of his mother. Minerva, it ſeems, appeaſed and pacified the *Furies*, ſo that they ceaſed to purſue him; upon which the Athenians ever after denominated them *Eumenides*.

But it muſt be obſerved, that, in truth, the Athenians called them by the ſame name long before Oreſtes's time, as appears from the Œdipus of Sophocles. There was a temple in Athens, near the Areopagus, conſecrated to the *Eumenides*, whom the Athenians called *venerable goddeſſes*: Ariſtides, and the ſcholiaſt of Thucydides, ſpeak of this temple as erected in memory of the judgment of Oreſtes.

FURIGELDUM, in *our old Writers*, a mulct paid for theft.

FURINALIA, in *Mythology*, feaſts inſtituted in honour of *Furina*, the goddeſs of robbers among the Romans. They were celebrated on the ſixth day before the calends of September. The goddeſs *Furina* had a Temple at Rome, and a prieſt called *flamen Furinalis*. Cicero repreſents this goddeſs as the ſame with the Furies; and Turnebus, in his Adverſaria, defends this opinion, alledging that Plutarch, in ſpeaking of the wood, conſecrated to *Furina*, where the younger Gracchus was killed, called it the wood of the Erynnies, or of the FURIES.

FURLING *lines* are ſmall lines made faſt to the top-ſails, top-gallant-ſails, and the mizzen-yard-arm; ſerving to *furl* up thoſe ſails, i. e. to wrap and bind them up cloſe to the yard. The mizzen has but one *furling* line, but all the reſt have two, one at each end. Thoſe that are uſed for the larger ſails are generally flat, and are known by the name of gaſkets.

FURLONG, an Engliſh long meaſure, containing the eighth part of a mile.

The Engliſh *furlong* is equal to forty poles or perches, and the perch to 16½ feet. Though in an old law-book, printed in Henry the VIIIth's time, we read, that ſix hundred feet, of five ſcore to the hundred, make a *furlong*.

In Scotland the *furlong* is equal to forty FALLS.

Hercules is ſaid to have run a ſtadium, or *furlong* at one breath.

FURLONG is alſo uſed for the eighth part of an acre, or half a rood.

FURLONG is ſometimes alſo uſed for a piece of land of more or leſs acres.

Omnibus Chriſti fidel. Johannes Blunt de Eye, arm.—Dedit Thomæ Croſt & Franciſco Level, arm. unum furlongum *terræ arabilis continen. per æſtimationem quatuor acras, &c. Dat. 20 Jan. 3 Eliz.*

FURLOUGH, in *Military Language*, a licence granted by an officer to a ſoldier to be abſent for ſome time from his duty. See DESERTERS.

FURNACE, an utenſil, or veſſel, proper to contain fire, or to raiſe and maintain a vehement fire in, whether of coal or wood.

There are divers kinds of *furnaces*, of various forms, and for various uſes.

The domeſtic *furnace*, uſed in making confections, &c. is uſually of iron, or earth.

Thoſe uſed by the goldſmiths, refiners, &c. are much larger, and of a different ſtructure.

Thoſe wherein lime, bricks, &c. are burnt, are called *kilns*.

FURNACE is particularly uſed for a kind of oven, wherein the ores of metals, after beating, waſhing, &c. are melted down by a great coal or wood fire.

The ſtructure and application of theſe *furnaces* are ſomewhat different, for the different metals.

Swedenborg has laid down, from his own experience, certain rules for the general conſtruction of theſe *metallurgic furnaces*, by which they will always be made more advantageous to the proprietor, cæteris paribus, than any other kind. Theſe rules are, that the chimney be always placed as nearly as may be, behind the centre of the *furnace*; that the ſmaller the depth of the fire-place, provided it be ſufficient to hold the coals, the better; that all *furnaces* muſt be the better, the wider they are forwards, and the higher they are, ſo as not to loſe the benefit of reverberation.

FURNACE is more ſtrictly applied to thoſe uſed in the melting of iron, which authors frequently confound with iron forges, though there is a conſiderable difference between them.

This *furnace* is a brick ſtructure, much in the ſhape of an egg ſet on end, wherein the iron ore, after it has been burnt in a kiln, is put, intermixed with cinders and charcoal, and the whole melted, till it trickle down in a receiver underneath; where the ſcum and droſs being taken away, the metal is thrown into furrows made in a bed of ſand, and thus is caſt into ſows or pigs of iron.

The forge is a place where the pigs are heated, and fuſed a ſecond, and even a third time, to prepare and fit them farther for uſe. See FORGE and IRON.

Theſe *furnaces*, as they are employed in running the moſt difficult of fuſion of all metals, ſo they are of all others contrived the largeſt, and capable of carrying heat to the greateſt degree. When they are to be uſed, they are firſt

firſt filled up to the top with coals; and the lower part being lighted, the top, and all other parts of the *furnace*, where the air could have paſſage are cloſed firmly up with iron plates laid one over another. The conſequence of this is, that the fire is put out, and the whole is kept in this ſtate ten or twelve days. At the end of this time the *furnace* is opened, and the coals are found all black, without a ſingle ſpark of fire in any part, yet extremely hot, and reduced to a tenth part of their quantity. When the *furnace* has been thus opened about a quarter of an hour, the matter begins to take fire of itſelf by the mere contact of the air. The firſt appearance of this is very remarkable; there ariſes a very bright flame from ſome of the coals, which plays about their ſurface, and ſpreads itſelf from one to another, without the appearance of the leaſt ſpark of fire in any part of any of the coals. The ore of the iron is for the firſt day put only in the middle of the *furnace*, and that but in ſmall quantity; the next day more, and every day afterwards more and more is put on, and by degrees it is ſpread over the whole ſurface of the *furnace* to the edges. This is the method of working the ore to the utmoſt advantage, and with the moſt diſpatch. The whole proceſs for one *furnace* of ore is finiſhed in about eight days from the time of the opening top; all the uſe of the firſt quantity of coal, is only thoroughly to warm the ſides and walls of the *furnace*; and it is after this to be kept carefully ſupplied with fuel, and the ore only ſpread out towards the ſides as the extreme heat, moſt ſenſible in the centre, increaſes. If too much be laid on of the ore at firſt, there is always a loſs from the quantity of metal. The quantity of the coals neceſſary to any given quantity of ore, differs in proportion to the advantageous or faulty ſtructure of the *furnace*. In the very beſt conſtructed ones, the weight of the coals and of the ore need be no more than equal. The flame which makes its way out of the bottom of the *furnace* is of different colours, according the nature of the ore and of the coals; ſometimes red, ſometimes yellow, and ſometimes green. That which iſſues out from the top of the *furnace* is of a red colour, and aſcends in a ſort of ſpiral line, reſembling the ſound of diſtant falls of water as it mounts up. With all the care that can be taken to heat the ſides of the *furnace*, and to keep them hot, the middle is always much the hotteſt, and the ore ſooneſt runs into metal there. Swedenborg de Ferro & Igni.

FURNACE, in *Chemiſtry*, is a receptable either of brick, iron, ſtone, or clay, wherein the fire, neceſſary for the ſeveral operations, is contained, determined, and directed.

The *furnace* conſiſts of ſeveral parts: as a place for the veſſel or body to be wrought on; a hearth, or hole for the aſhes; a chimney; a grate; a door; a dome; and a fan, or elſe regiſters, whereby to let in air, to increaſe or abate the fire.

The perfection of a *furnace* conſiſts in its maintaining a conſtant, equitable fire; and this eaſily tempered, and at an eaſy expence.

To have the expence eaſy, the whole action of the fire, or fuel, muſt be employed on the ſubject that is to undergo the operation.

It muſt be equable, ſince different degrees of fire have different effects: ſo that if any given degree would anſwer any given intention, an alteration of that degree will prevent the intention from taking place. And on theſe circumſtances does all the variety of *furnaces* depend.

Furnaces are either *fixed* and immovable, called *athanors*; or *portable*, called *catholic*, i. e. univerſal, as being proper for all operations, where the body to be operated on is not too large.

The firſt ſpecies of athanor, or fixed *furnace*, is fitted to maintain an equal heat, and ſuch as ſhall laſt a long time without addition of freſh fuel.

The ſecond is the *furnace* of the *balneum Mariæ*, fit for the diſtillation of the more ſubtil ſpirits.

The third is the digeſting *furnace*. See DIGESTION.

The fourth is the anemius, or *wind furnace*, called alſo *melting furnace*, and *metallic furnace*; uſed in the fuſion of metals, minerals, and vitrifications.

It is called *wind furnace*, becauſe the air drives forcibly in, to blow up the coals.

For an account of the principal *furnaces* uſed in chemical and other operations, ſee the following articles.

FURNACE, *almond*, or *almon*. See ALMOND.

FURNACE, *aſſaying*, *cupelling*, or *aſſay*, (ſee *Tab.* III. *Chemiſtry*, *fig.* 37.) is made in the following manner: 1. Make with iron plates a hollow quadrangular priſm, eleven inches broad and nine inches high *a a*, *b b*, ending at top in a hollow quadrangular pyramid *b b*, *c c*, ſeven inches high, terminating in an aperture at top ſeven inches ſquare. This priſm muſt be cloſed at bottom with another iron plate, which ſerves as a baſis or bottom to it *a a*. 2. Near the bottom make a door *e*, three inches high, and five inches broad, that leads to the aſh-hole. 3. Above this door, and at the height of ſix inches from the baſis, make another door *f*, of the figure of a ſegment of a circle, four inches broad at its baſis, and three inches and a half high in the middle. 4. Then faſten three iron plates on the forepart of this *furnace*; let the firſt of them *g g*, eleven inches long and half an inch high, be faſtened, ſo that its lower edge ſhall reſt againſt the bottom of the *furnace*, with three or four rivets, and in ſuch a manner, that there may be between the upper edge of the ſaid plate and the ſide of the *furnace* a groove ſo wide, as that the ſliders of the lower door *k k* may be put into it, and freely move backwards and forward therein: theſe muſt be made of a thicker iron-plate. The ſecond iron-plate *h h*, eleven inches long, three inches high, and perfectly parallel to the foregoing plate, muſt be faſtened in the ſpace between the two doors, in ſuch manner, that both the upper and the lower edge of it may form a hollow groove with the ſide of the *furnace*. One of theſe grooves, which is turned downwards, ſerves to receive the upper edges of the ſliders that ſhut the lower door N° 2. The other, that turns upwards, is to receive the inferior edges of the ſliders of the ſmall door above. N° 3. The third plate, *i i*, which is like the firſt, muſt be rivetted cloſe above the upper door, in ſuch manner, that it may form a groove turning downwards, and contiguous to the upper edge of the upper door, N° 3. 5. In order to ſhut up both doors, N° 2 and 3, you muſt adapt to each of them two ſliders made of iron plates, that may move within the above mentioned grooves *k k*, *l l*; but the two ſliders belonging to the upper door, N° 3. muſt have each a hole near the top; that is, one a ſmall hole one fifth part of an inch broad, and one inch and a half long *m*; and the other a ſemi-circular aperture one inch high and two inches broad *n*. Let, beſides, each ſlider have a handle, that they may be laid hold of when they are to be moved. 6. Moreover, let five round holes, one inch broad, be bored in the *furnace*, two of which muſt be made at the fore part of the *furnace* *o o*, two others in the back part, all at the height of five inches from the bottom, but three inches and a half diſtant from each ſide of the furnace; and, finally, a fifth hole *p*, at the height of one inch above the upper edge of the upper door *f*. 7. In ſhort, let the inſide of the furnace be armed with iron-hooks, jetting out half an inch, and about three inches diſtant from each other, to faſten the lute with which the *furnace* is to be covered over within. 8. Let then an iron, movable, hollow, quadrangular pyramid *q*, three inches high, be adapted to the upper aperture *d* of the *furnace*, at the baſis ſeven inches broad, ending upwards in a hollow tube *r*, three inches in diameter, two inches high, almoſt cylindrical, though ſomewhat convergent at top. This prominent tube ſerves to ſupport a funnel or flue, which is almoſt cylindrical, hollow, made of iron-plates, and two feet high, and which, when a very ſtrong fire is required, is put perpendicularly upon the ſhorter tube, in ſuch manner, that it enters cloſe into it, one inch and a half, or two inches deep, and may again be taken off at pleaſure, when there is no need of ſo ſtrong a fire. But this pyramidal cover *q* muſt beſides have two handles *s s*, adapted to it, that it may be laid hold of, and thus be taken away or put on again: and that this, being put on the aperture *d* of the *furnace*, may not be eaſily thrown down, let an iron plate be rivetted to the right and left upper edge of the furnace *e e*, and be turned down towards the inſide, ſo as to make a furrow open before and behind, into which the lateral edges of the cover may enter and be faſtened, and at pleaſure be moved backwards and forwards, whenever it muſt be put on, or moved. 9. Let a ſquare ledge, made of a thick iron-plate, be faſtened at the top of the upper edge of the lower door *e e*; this is deſigned to ſupport the grate and the lute: but it muſt be made of two pieces, that it may be eaſily introduced into the cavity of the *furnace*. Thus you will have an aſſay-oven, which muſt afterwards be covered over on the inſide with LUTE. This you are to do as follows: That the fire may be better confined, and that the iron may not be deſtroyed by growing red-hot, the whole inſide of the *furnace* muſt be covered over with lute, one finger or one finger and a half thick. But, before you cover the inſide of your *furnace* with this lute, you muſt firſt put within the *furnace* ſmall iron bars, equal in length to the diameter of the oven, quadrangular, priſmatical, half an inch thick, having their extremities ſupported by a ſquare iron ledge, and three-fourths of an inch diſtant from each other; and you muſt faſten them ſo, that their flat ſides may be oblique with regard

to the transverse section of the *furnace*, and that the two oppoſite angles may look one upwards and the other downwards; the bars muſt not be laid flat, but edgeways, by which ſituation you hinder the aſhes of the fuel of the fire from being detained too long between the interſtices of the ſaid iron-bars, and from making an obſtruction that would oppoſe the free draught of the air. The *furnace* being then covered over with lute, and dried up by a gentle heat, is at laſt fit for docimaſtical operations, and eſpecially for ſuch as muſt be performed in the aſſay-oven.

If then an operation is to be made in the *furnace* hitherto deſcribed, you muſt let through the four lower holes above deſcribed, of the *furnace a a*, placed before and behind, and directly oppoſite to each other, two iron-bars one inch thick, and long enough that their extremities on every ſide may juſt out of the holes a ſmall matter. Theſe ſerve to ſupport the MUFFLE and its bottom. You then introduce the muffle through the upper aperture of the *furnace d*, and place it upon the above deſcribed iron-bars, in ſuch manner, that the open foreſide of it be contiguous to the inward border of the upper door *f*. The fuel of the fire is introduced through the top of the furnace *d*; the cover of which, on this account, muſt be moveable, and not very heavy *q*. The beſt fuel for the fire is charcoal made of the hardeſt wood, eſpecially of beech, broken into ſmall pieces of the bigneſs of an inch, wherewith the muffle muſt be covered over ſome inches high. We then reject larger bits of coals, becauſe they cannot fall through the narrow interſtices, between the ſides of the muffle and thoſe of the *furnace*, and cannot of courſe ſufficiently ſurround the circumference of the muffle. Whence it happens, that there are on every ſide places void of fuel, and the fire is either not ſtrong enough or unequal. But if, on the contrary, you uſe coals too ſmall, then a great part falls immediately through the interſtices of the grate into the aſh-hole; and the tendereſt particles of them turn too ſoon into aſhes, and by increaſing the heap of aſhes, obſtruct the free draught of the air, which is here greatly requiſite.

A perfect management of the fire is moſt commonly neceſſary in the performing of operations in this *furnace*; therefore the reader muſt give attention to what follows: if the door of the aſh-hole *e* is quite open; and the ſliders of the upper door *f* drawn towards each other, ſo as to touch one another in the middle of the door, and if, beſides, the cover *q*, and the funnel adapted to its tube *r* is upon the top *q* of the *furnace*, the fire will be then in the higheſt degree poſſible; though, in the mean time, it is hardly ever neceſſary to put the funnel on, except in a very cold ſeaſon: but if, after having diſpoſed the furnace in the manner juſt deſcribed, you put red burning coals into the open upper door *f* of it, the fire is ſtill more increaſed thereby: however, this artifice is never, or very ſeldom, neceſſary. When you ſhut the upper door with only that ſlider that has a narrow oblong hole in it *m*, then the heat becomes a little leſs; but it diminiſhes ſtill more when you ſhut the door with the other ſlider that has in it the ſemi-circular hole *n*, which is larger than that of the firſt ſlider: nay, the heat again is leſs when you take away the funnel put at the top of the cover: finally, the door of the aſh-hole being either in part or totally ſhut, the heat is ſtill diminiſhed, becauſe the draught of the air, ſo neceſſary to excite the fire, is hereby hindered: but if, beſides all theſe, you likewiſe open the upper door quite, then the cold air, ruſhing into the muffle, cools the bodies put under it that are to be changed, to a degree never required in any operation, and ſuch as will entirely hinder the boiling of lead. If, during the operation, the fire begins to decay, or to grow unequal, it is a ſign that there are places void of coals between the ſides of the *furnace* and thoſe of the muffle; therefore, in this caſe, you muſt ſtir your coals on every ſide with an iron rod, which is to be introduced through the upper hole *p* of the *furnace*, that they may fall together, and thus act in a proper manner and equally. See Cramer's Art of Aſſaying, by Dr. Mortimer, p. 75. See *Portable* FURNACES.

FURNACE, called *Athanor*, or *tower-furnace*, is repreſented in *fig.* 38. See ATHANOR. It is thus conſtructed. 1. Let a ſmall ſquare hollow tower *a a a a* be formed of ſuch ſtones, or of bricks made of Stourbridge clay, or Windſor loam, as may reſiſt the fire; let the ſides of it be ſix inches thick, and forming a ſquare cavity within, of ten inches on each ſide *b b b b*. The height of it is determined according as it is to keep up the fire long, without any addition of new fuel: five or ſix feet are moſt commonly ſufficient. 2. At the bottom of this tower make an opening *c*, ſix inches broad, and as many inches high; hang to it an iron door, being on every ſide one inch broader than the opening, and ſuch as may ſhut it very cloſe: for which purpoſe the external edge of this opening muſt be excavated all round in ſuch a manner, that it may form a groove one inch broad, into which the edges of the door may be received. 3. At the diſtance of ten inches from the bottom of the tower, put a grate *d*, made of priſmatical quadrangular iron bars, one inch thick, and three quarters of an inch diſtant from each other: let alſo each of theſe iron bars be ſo ſituated with regard to the tower, that the two oppoſite acute edges of each may look perpendicularly, one downward, the other upwards, that, by this means, the aſhes may eaſily fall into the aſh-hole. 4. Make above this grate an opening circular at top *e*, ſix inches high, ſeven inches broad, that may, as well as the aſh-hole, N° 2. be opened and ſhut with an iron door. 5. Adapt to the top of the tower an iron cover *f*, exceeding the aperture of the tower all around two inches, and having a handle, wherewith it may be eaſily taken away, and put on again. Thus you are to make the *furnace* called in Latin *furnus primarius*. 6. Then cut out in any ſide of the tower, for inſtance in the left, an oblong ſquare aperture, going up obliquely towards the outſide *g g*, four inches and a half high, ten inches broad, having its inward inferior edge one inch and a half, or two inches above the grate *d*; that by the intervening of this hole, the cavity of this tower may communicate with another immediately to be deſcribed. 7. Nearly over-againſt the ſame ſide of the tower, make a cavity with ſtones, whoſe inferior part muſt be a hollow priſm *b, b, b, b*, ſix inches high, twelve inches broad, ending at top in a ſemi-cylindrical arch *i, i*, deſcribed by a radius of ſix inches; that by this means, the height of the whole cavity may be twelve inches in the middle. Let this anterior cavity be totally open, though when requiſite, it is to be ſhut very cloſe with an iron plate *k, k*, whoſe inward ſurface is to be conſtructed in the ſame manner as is preſcribed for the ſliding door of the melting furnace, and then luted two inches thick within. Moreover, let there be in the middle of this plate, a round hole, four or five inches in diameter, and let the circumference of this hole have an iron cylindrical border made to it, and prominent within; that by means of it, the lining of lute within may be ſupported, and kept from falling down eaſily. Let a noteh one inch broad, and two inches deep be made in the outward circuit of the aperture of this cavity, to receive the extremity of the plate that ſhuts the aperture. The hole of this plate either is ſhut with a ſtopple, or ſerves to paſs the neck of the retort through. This plate likewiſe is faſtened with two bolts *n, n*, to be put horizontally with iron hooks *o, o, o, o*, driven into the wall near the edge of the aperture, ſo that one bolt may faſten the upper part of the plate, and the other the lower. 8. It is moreover proper, that the ſquare aperture *g g*, through which the fire enters from the tower into the cavity hitherto deſcribed, N° 7. may be ſhut and opened at pleaſure with an iron ſlider: for if this is not done, an exceſſive fire, employed ſometimes by an unexperienced hand, cannot be ſo eaſily checked. For this purpoſe, let a flit half an inch broad, and eleven inches long, be left in the wall that conſtitutes the upper part of the cavity N° 7. and is contiguous to the tower; ſo that it may exceed the length of the ſquare aperture *g, g*, a ſmall matter on every ſide, and reach before and behind into the ſmall groove, going down along the perpendicular ſides of the ſaid aperture, *g, g*, and retain the iron ſlider to be put into it to keep it ſteady. However, let this iron ſlider be ſix lines thick, eleven inches broad, and five inches high: and let a couple of ſmall iron chains, *p, p*, be faſtened on each ſide of its upper edge, wherewith the ſlider may be liſted up and let down again. Therefore let a couple of ſtrong iron nails be drove into the contiguous wall of the tower, perpendicularly over thoſe places in which the ſaid ſmall chains are faſtened to the iron ſlider, that any of the links of the chains may be ſuſpended on them at pleaſure. Moreover, let the upper edge of the flit above deſcribed be entirely ſhut up with ſtones and cement, leaving only two ſmall holes through which the ſmall chains may be paſſed. On the left of this cavity (N° 7.) and at the diſtance of eight inches from the bottom of it, let a ſquare, *q, q, q, q*, chimney or funnel be erected with bricks, three inches and a half in the clear, four foot high, and a ſmall matter convergent upwards, ſo that the diameter of it at top may be three inches. This funnel muſt be contrived to be ſhut cloſely with an iron ſlider, having a handle to it, *r, r*, which ſlider muſt move freely between a double iron ſquare frame faſtened in the walls of the funnel, at ſuch a height from the hearth as ſhall ſeem convenient to any artificer. 10. Below this chimney let a ſquare aperture be made, like the foregoing

ing (N° 6. *f*, *f*), leading obliquely up to the bottom of another cylindrical cavity, *s*, *s*, *s*, *s*, which is eight inches deep, described by a radius of six inches, open at top and there converging inwardly into a border one inch thick, and six lines broad, designed to ſupport an iron pot. Likewiſe, cut in the anterior wall of this cavity, and at the upper part of its mouth, a ſegment two inches and a half deep, five inches broad, and ſtooping forward, *v*, *v*, to receive the neck of the retort. 11. To this cavity (N° 10.) belongs an iron pot, *w*, *w*, eleven inches broad, and about nine inches deep, which muſt be encompaſſed with an iron ring, *x*, *x*, one inch broad, and faſtened at the diſtance of one inch and a half from the upper end of the pot. Let a ſegment, *y*, be likewiſe cut off the upper edge of this pot, which ſegment muſt be four inches and a half deep, and five inches broad; the iron ring juſt deſcribed muſt be bent all round the edges of this ſegment. 12. Overagainſt the aperture, *t*, *t*, which communicates from the firſt cavity (N° 7.) into the ſecond (N° 10.) let another ſuch aperture, *u*, be made, two inches diſtant from the bottom of the ſecond cavity (N° 10.) perfectly like the foregoing, *t*, *t*, *t*, *t*, and communicating obliquely upwards with a third cavity, *i*, *i*, *i*, *i*, like and equal to the ſecond cylindrical cavity, *s*, *s*, *s*, *s*, that the fire may paſs from the latter into the former. 13. In the hinder part of the wall which makes the aperture juſt mentioned, *z*, let a chimney like the foregoing, *q*, *q*, *q*, *q*, and of the ſame height, 2, 2, 2, 2, be erected, which may be ſhut with a ſlider like that, 3. * 14. Finally, on the left ſide of the third cavity let an aperture be made in the ſame manner, 4, and like the foregoing ones, *g g t t*; more remote however from the bottom of the cavity, without a paſſage at the other extremity and communicating only with the cavity of the third chimney, 5, 5, 5, which muſt be erected in the ſame manner as the two foregoing ones, *q*, *q*, *q*, *q*, 2, 2, 2, 2. Thus you will have a *furnace* very proper for a great many operations.

We are now to ſpeak of the uſe of the athanor juſt deſcribed; and chiefly to mention to what operations each of its parts ſerve in particular, and then how the fire may and muſt be governed in it. 1. You muſt put at the upper arched door, *e*, of the tower a ſemi-cylindrical muffle twelve inches long, which muſt be introduced through the door; which for this reaſon muſt be of the ſame height and breadth as that door, three quarters of an inch thick, and open behind, being ſhut there by the hinder part of the athanor, as far as which it muſt reach. For this purpoſe, a tile muſt be ſet upon the grate, *d*, to ſupport the muffle. Let alſo this muffle have ſmall pieces cut out near its baſis, as common aſſay muffles. You may put under this muffle your cement pots, or ſuch bodies as muſt be calcined with a long and violent fire; which can be done without a muffle, though not ſo neatly. 2. In the firſt chamber, *b b*, *b*, *b*, *i*, *i*, you may make the moſt violent diſtillations with an open fire; for retorts or large veſſels are introduced into it, after you have taken away the door, *i*, *i*, *i*, and are put either upon the hearth itſelf of this chamber, or upon a particular ſupport of ſtone. But you muſt place theſe veſſels in ſuch manner, that their necks may eaſily paſs through the hole of the door, when put on again; for which purpoſe, they muſt be ſet higher or lower by means of three ſcrews. 3. In this ſame chamber, inſtead of diſtillations, you may alſo make cementations, calcinations, &c. in which caſe the round hole of the iron plate may be ſhut and again opened with a ſtopple, that one may view the inſide. 4. The ſecond and third cavities, *u*, *u*, *u*, *u*, *i*, *i*, *i*, *i*, ſerve chiefly to ſuch operations as are made in baths (or beds) of *ſand-aſhes*, or *filings*. For inſtance, you put into each of the cavities a pot, *v*, *v*, and you ſtop with thin lute or with ſand, which muſt previouſly be moiſtened, the ſlip between the iron ring, *x*, *x*, and the border of the cavity, upon which this ring reſts. 5. Beſides, you may alſo make, in theſe two cavities, diſtillations by a reverberating fire, as well as in the firſt: only the fire is leſs violent in theſe, though ſufficient to extract aqua fortis. You then take out the iron pot, *v*, *v*, and inverting it, you put it upon the mouth of the chamber; ſo that the brim of the pot, being the depth of one inch and a half above the iron ring *x*, *x*, wherewith this pot is furrounded, may be received within the mouth of the cavity; and ſo that the ſegment cut in the pot may, together with the ſegment cut out from the ſide of the cavity *v*, *v*, form a hole to let the neck of the veſſel through. 6. All the apparatus being thus ready, you firſt introduce through the top of the tower *b*, *b*, *b*, *b*, a few burning coals; and put upon them ſome of the unkindled fuel of the fire, that the cavity of the tower may, according as it is thought neceſſary, be filled either entirely or only in part. Then with all ſpeed you put upon it the iron cover *f*, and ſtrew the border of this on the outſide with ſand or aſhes, which you preſs gently with your hands: for if you ſhould neglect this point, all the fuel contained in the tower would be kindled, and may endanger ſetting the houſe on fire.

We ſhall here annex a few general rules concerning the regimen of the fire in this furnace: for it is hardly neceſſary to explain all particulars, ſince practice will eaſily hint them to ſuch as ſhall be ever ſo little acquainted with chemiſtry. The fire may be made very ſtrong in the firſt chamber *b*, *b*, *b*, *b*, *i*, *i*, when the door of the aſh-hole *c*, and the funnel *q*, *q*, *q*, *q*, of the chamber is quite open, and when the iron ſlider, ſuſpended with chains *6*. *p*, *p*, does not hinder the fire from paſſing freely from the tower into this cavity. But the cloſer the funnel is ſhut, together with the door of the aſh-hole, the more the violence of the heat diminiſhes: and this will be ſoon effected, if the iron ſlider ſuſpended with chains is let down in part: for the fuel contained in the tower burns at leaſt as high as the ſpace between the lower edge of the iron ſlider and the grate *d*. Obſerve beſides, in thoſe operations wherein the round hole of the door is ſtopped with a plug, that when the ſtrongeſt fire is required, this hole muſt not be kept long open, becauſe the air ruſhing violently through it, ſoon cools the bodies put into the cavity. The operations above mentioned may be performed in the ſecond and third chamber, in, and at the ſame time, and with the ſame fire, as they are in the firſt chamber; for the fire penetrates from the firſt cavity into the ſecond, and increaſes when the funnel 2, 2, 2, 2, (ſuch funnel is opened: but before you do this, the funnel of the firſt cavity muſt be ſhut as much as that of the ſecond is opened. By the ſame means, you may hinder the fire which ſerves for the operations made in the two firſt cavities, from going out through the funnels, and you force it out, on the contrary, through the third cavity and through its funnel 5, 5, 5, that it may alſo act upon the bodies placed in that cavity. For the more the funnel erected upon the third cavity is open, the more one, or even both funnels of the other two cavities muſt be cloſed: thence it is plain, that you cannot kindle the ſtrongeſt fire in the third cavity, unleſs there be one equally ſtrong in the other two; and that, on the contrary, the heat in the third cavity may be rendered leſs, by cloſing its funnel; though it be violent in the others. The ſame is true of the ſecond cavity, with regard to the firſt. Finally, you cannot make the ſtrongeſt fire under the muffle placed within the upper door *e* of the tower, unleſs you have an equal fire in the firſt cavity, which fire may conſequently be increaſed, by ſhutting the door quite againſt the muffle *e*, and diminiſhed by opening it; there being mean while an equal heat in the firſt chamber, and in the following ones. Cramer, and Chem. Dict. Appendix.

This ſort of *furnace* is now much neglected, ſince the long and laborious operations of the ancient chemiſts, who were in ſearch of the art of making gold, have been diſcontinued: it is alſo ſubject to an inconvenience, as the fuel in the tower is apt to ſtick there, or fall down at once in too great quantity.

FURNACE, *bellows*, or *blaſt*, is one of the two kinds of *furnace* uſed in coinage for the fuſion of metals. It conſiſts of a flat hearth at bottom, into which the air may be admitted by a hole contrived therein.

On a level with the hearth is a ſecond aperture, which gives paſſage to the pipe of the bellows, from which the *furnace* is denominated: about a foot over this is a moveable grate, which may be taken off, and put on, at pleaſure: laſtly, over this is the place where the crucible is ſet, which is ſquare, and made of the ſame earth with the crucible, of breadth ſufficient to bear a range of coals around the crucible. To melt a metal in this *furnace*, they lay a little plate of forged iron over the grate, and on this they ſet the crucible, which is likewiſe covered with an iron or earthen lid; then they fill the *furnace* with charcoal, and when it is well lighted, and the crucible ſufficiently hot, they ſtop the vent-hole: laſtly, throwing on freſh coals, they ſtop the *furnace* with an iron lid; thus continuing to work the bellows, and ſup-

ply

ply fresh fuel, till the metal be in fusion. These bellows should be double, like those used by the smiths, that the blast may be continual; though no heat can be produced by this means, to exceed that which may be obtained in a good *wind*-FURNACE. The principal use of bellows is to excite a great heat in a little time.

Dr. Lewis, in his ingenious contrivance of *portable* FURNACES, proposes to fit up a black leaden crucible or pot for a *blast furnace*, in which no other aperture is required than a round one in the side, through which the nose of the bellows passes; and the fuel is to be thrown in at the top. The pot chosen for this purpose should be of the largest size; and if a cover or dome, or an additional part for enlarging its capacity be wanted, another pot, with a portion of its lower narrow part sawed off, makes a very convenient one. A round plate or slip, sawed from the solid part of the bottom, serves very commodiously both for a grate and for a support to the crucible; eight or nine holes, about three quarters of an inch in diameter, are bored round the outer part of the plate, for the transmission of the air forced in by the bellows, which holes are made to widen downwards, to prevent their being choked up by pieces of the fuel. Four or five small crucibles may be placed together on the middle of this plate. See *fig.* 29. The bellows which Dr. Lewis chiefly employed is the organ bellows, so constructed, that the upper board, instead of rising obliquely on hinges at one side, rises equally on all sides, and continues always horizontal. The leather of this kind of bellows is more flexible than that of the common ones, and does not, like them, resist unequally according to the greater or less extension of the folds. The board is pressed down, and the air forced out by a weight on the top, which weight, acting always perpendicularly, has always an equal power, and the air is driven out in one unvaried current. This advantage may also be given to the common bellows by hanging the weight at the extremity, on an arc, furnished with a groove for receiving the cord, and whose centre is the point on which the board moves: by this contrivance, the heat is kept up uniform, and may be easily increased at pleasure, by increasing the weights; and for this purpose, the nozzel of the bellows should be wider than usual, that the air may be more freely discharged from it. The bellows is of no incumbrance in the LABORATORY, being inclosed in a wooden case, whose cover does the office of a common table; to the nozzle, which just comes through the cross bar at the bottom of the table, is occasionally fitted a pipe reaching to the *furnace*. The bellows, thus disposed, will also serve for impelling and concentrating the flame of a lamp on bodies exposed to it. For this purpose, an upright tin tube is fitted on the nozzel by a short elbow at its lower end; and at its upper end is a moveable elbow, into which is inserted a lesser pipe, having a very small aperture in its extremity: this aperture, being applied to the flame of a lamp placed upon the table, and the pipe blown through, the flame lengthens in the direction of the blast, and converges into a small space, producing there a very great heat. The bellows above described may be made lighter and more commodious, by using a stiff rod, for moving the lower board, instead of the flexible cord or chain commonly employed. Some, instead of a bellows, have substituted an ÆOLIPILE, which is about half filled with water, and set on burning charcoal, with its neck directed to and at a small distance from the fire to be excited: as soon as the water begins to boil, an elastic vapour issues vehemently through the small orifice, and animates the fire like air impelled by bellows; whence this instrument has been called the Æolian bellows and philosophers bellows: some have employed the æolipile in the same manner as the common bellows, by inserting its neck into the cavity beneath the grate of a *furnace*; but Dr. Lewis condemns this method, and observes, that, in all cases, where the vapour does not pass through a portion of the atmosphere before its admission to the burning fuel, it extinguishes, instead of exciting, the fire.

In operations which require a considerable degree of concentrated heat, it has been proposed to impel a number of flames into one point, by streams of air driven from different parts of the circumference of the fuel to the middle, by means of several bellows placed round the *furnace*. But a number of bellows being incommodious, Dr. Lewis has contrived to multiply the streams of air with one bellows. The pot, which serves as a *furnace* for this purpose, has a number of holes bored at small distances, in spiral lines all over it, from the bottom up to such height as the fuel is designed to reach to. The crucible is placed on a proper support in the bottom; and the holes are obliquely directed towards the crucible, so that the impelled heat plays in a kind of spiral upon its surface: the pot, which serves for the blast *furnace*, already described, with an iron ring at the top receives this perforated pot so far, that all its holes are within the cavity, which cavity has no other outlet than the round aperture for the bellows; and, therefore, the air, thus blown in, will distribute itself through the perforations of the inner pot. See *fig.* 40. C represents the *furnace*, D a transverse of it, and E is its cover, being an iron plate with a round hole in the middle, and a handle. By means of this contrivance, the crucible is expeditiously heated, and with a small quantity of fuel, to an intense degree; and yet the exterior parts of the fuel have no great heat, so that the operator may approach the apparatus without inconvenience. A close-bottomed pot, like that used for the blast *furnace* already described, without a grate, will make a *furnace* for the fusion of metals, the revival of metallic calces, and the smelting or assaying of ores, *trans carbones*, as it is called, or in contact with the burning fuel, as practised in the large works. The *furnace* being intensely heated, and almost filled with *fuel*, some of the subject-matter is sprinkled upon the coals, chiefly about the middle, and towards the side opposite to the bellows, but with care that it no where touch the side: more charcoal is thrown over it; and the fire, according to the nature of the subject, is kept up strong, or abated, by lessening the weight upon the bellows; and the alternate injection of the subject-matter and charcoal continued; the metal and slag, melting and dropping down through the coals, are collected from the bottom. Lewis's Com. Phil. Techn. p. 18, &c.

FURNACES *for making the finer kinds of colours*, are those for subliming CINNABAR, for making VERMILION, for subliming *king's* YELLOW, and for calcining blood for making *Prussian* BLUE, OKER, ULTRAMARINE, &c. For the method of their construction and use, the curious reader is referred to Dossie's Handmaid to the Arts, vol. i. p. 15, &c.

FURNACE, *coupelling*. See ESAMEL, and Handmaid to the Arts, vol. i. p. 267, &c.

FURNACE, *founder's*, is of divers kinds, according to the different kinds of work to be cast. See FOUNDERY *of small works*, &c.

The statuaries, or figure-makers, use two kinds of *furnaces*; which see described under FOUNDERY *of statues*.

FURNACE, *glass-house*, is the place wherein the ingredients or materials of glass are fused and vitrified.

There are three kinds of *furnaces* used in the glass-works. The first, called the *calcar*, serves to prepare or calcine the frit in. It is made in fashion of an oven, ten feet long, seven broad, and two deep. The fuel, which is sea-coal, is put in a trench, on one side of the *furnace*; and the flame reverberates from the roof back upon the frit. The coals burn in an iron grate, and the ashes fall hence into a hole underneath.

The second is the *working furnace*, serving to melt the metal in, or make the glass. Its figure is round, three yards in diameter, and two high, being arched over: round the inside there are eight or more pots placed, and piling-pots on these: the number of pots is always double that of the boccas or mouths, or that of the workmen, that each may have one pot refined to work out of, and another for metal to refine in, while he works out the former.

The *furnace* has two partitions: the lower separating the pots from the fire-place, has a circular hole in the centre, covered with a grate, through which the flame passes from the fire-place into the *furnace*: from the arched sides and roof whereof it is reverberated into the melting-pots.

The second partition divides this from the leer, or annealing *furnace*: through the boccas, or working-holes, the metal is taken out of the pots, and the pots put into the *furnace*; these boccas are stopped with moveable covers, made of lute and brick, to screen the workmen's eyes from the fire: on each side the bocca is a boccarella, out of which coloured glass, or the finer metal, is taken from the piling-pot. To the *furnace*, likewise, belong ovens, or holes, near the leer, for the calcining of tartar, iron, &c.

The *leer*, which serves to anneal and cool the vessels, and which Agricola makes a particular *furnace*, consists of a tower, besides the leer: the tower lies directly over the melting *furnace*, with a partition betwixt them a foot thick, having an aperture, called *ochio*, or *lumella*, through which the flame or heat ascends out of the *furnace* into the tower: on the floor or bottom of this tower, the vessels, fashioned by the artists, are set to anneal; this has also two boccas, or mouths, by which the glasses are put in with a fork, and set on the floor.

The leer is an avenue five or six yards long, continued to the tower; through this the glasses, when annealed, are drawn in iron pans, called *fraches*, by which they come

to

to cool by degrees; being quite cold, by that time they reach the mouth of the leer, which enters the faroſel, or room where the glaſſes are to be ſet.

The third is the *green-glaſs furnace*, which is a kind of compound of all the former. It is made ſquare (the two former being circular), having an arch at each angle thereof for annealing and cooling the glaſſes. The metal is wrought on the two oppoſite ſides, and on the other two they have their calcars, into which are made linnet-holes for the fire to come from the *furnace*, to bake the frit; as, alſo, to diſcharge the ſmoak. Fires are made in the arches, to anneal the veſſels; ſo that the whole proceſs is done in one *furnace*.

The materials wherewith the inſides of theſe *furnaces* are built, are not brick (which would ſoon melt down into glaſs, as alſo all the ſofter ſtones), but hard and ſandy kinds, by Imperatus called *pyramachia*. See GLASS, and GLASS-*pots*.

FURNACE, *glaſs painters*. See *Painting in* GLASS.

FURNACE, *hatters*, are of three kinds; a little one under the mould whereon they form their hats; a larger, in the ſcouring room, under a little copper full of water and lees: and a very large one under the great copper, in which they dye their hats.

FURNACE, *lamp*, is a kind of ATHANOR, in which the heat is produced and maintained by the flame of a lamp introduced within it. This *furnace* has evidently no occaſion for an aſh-hole, a grate, or a fire-place. It has only one opening below, through which the lamp is introduced, and a kind of ſmall chimney made in its upper and lateral part, for circulation of air, to keep up the flame of the lamp, and to give vent to the ſmoke. A *furnace* of this kind is very convenient for diſtillations, which require little heat. It may be eaſily furniſhed with a water-bath, or ſand-bath; and it is particularly uſeful for digeſtions. Dr. Lewis obſerves, that in the common lamp-*furnaces*, the lamps require frequent ſnuffing, and ſmoke much; and the ſoot, accumulated on the bottom of the veſſel placed over them, is apt, at times, to fall down, and put out the flame. Theſe inconveniencies were, in a great meaſure, remedied by the following conſtruction.

The lamp conſiſts of a braſs pipe, ten or twelve inches long, and about a quarter of an inch wide, inſerted at one end into the reſervoir of the oil, and turned up at the other to an elbow, like the bole of a tobacco-pipe, the aperture of which is extended to the width of near two inches. On this aperture is fitted a round plate, having five, ſix, or ſeven ſmall holes, at equal diſtances, round its outer part, into which are inſerted as many pipes about an inch long: into theſe pipes are drawn threads of cotton, all together not exceeding what in the common lamps form one wick; by this diviſion of the wick, the flame expoſes a larger ſurface to the action of the air, the fuliginous matter is conſumed and carried off, and the lamp burns, clear and vivid.

The reſervoir is a cylindric veſſel, eight or ten inches wide, compoſed of three parts, with a cover on the top. The middle partition communicates, by the lateral pipe, with the wicks; and has an upright open pipe ſoldered into its bottom, whoſe top reaches as high as the level of the wicks; ſo that, when this part is charged with oil, till the oil riſes up to the wicks in the other end of the lamp, any farther addition of oil will run down through the upright pipe into the lower diviſion of the reſervoir. The upper diviſion is deſigned for ſupplying oil to the middle one; and, for that purpoſe, is furniſhed with a cock in the bottom, which is turned more or leſs, by a key on the outſide, that the oil may drop faſt enough to ſupply the conſumption, or rather faſter, for the overplus is of no inconvenience, being carried off by the upright pipe; ſo that the oil is always, by this means, kept exactly at the ſame height in the lamp. For common uſes, the middle diviſion alone may be made to ſuffice: for, on account of its width, the ſinking of the oil will not be conſiderable in ſeveral hours burning. In either caſe, however, it is expedient to renew the wicks every two or three days: oftener or ſeldomer, according as the oil is more or leſs foul; for its impure matter, gradually left in the wicks, occaſions the flame to become more and more dull. For the more convenient renewing of them, there ſhould be two of the perforated plates; that, when one is removed, another with wicks, fitted to it, may be ready to ſupply its place.

One of the black-lead pots, deſcribed under the article *portable* FURNACES, makes a proper *furnace* for the lamp. A pot of this kind requires no other aperture than one in the bottom for admitting air, and one in the ſide for the introduction of the elbow of the lamp. The ſtopper of the ſide aperture conſiſts of two pieces, tha. it may be conveniently put in after the lamp is introduced; and it has a round hole at its bottom fitting the pipe of the lamp.* By theſe means, the *furnace* being ſet on a trivet or open foot, the air enters only underneath, and ſpreads equally all round, without coming in ſtreams; whence the flame burns ſteady. The heat ſhould not be raiſed higher than about the 450th degree of Fahrenheit's thermometer, which degree of heat is ſomewhat more than ſufficient for keeping tin in perfect faſion. See *fig.* 41. Over the lamp *furnace*, as repreſented in the figure, there is a broad pan, which is employed as a water-bath, and contains a long-necked matraſs or bolt head; or other commodious veſſel of the ſame kind, compoſed of a glaſs receiver, with a long pipe inſerted into its mouth, and a cucurbit, or body with a glaſs-head, for diſtillation, Lewis's Com. Phil. Techn. p. 29.

FURNACE, *letter-founders*, is very ſmall, not exceeding a foot and a half in height, and a foot in diameter; being placed on a wooden ſtand, or bench, to raiſe it to a proper height for the artiſt, who works ſtanding. It is made of the ſame earth with crucibles. See *Letter*-FOUNDERY.

FURNACES, *lute for*. See LUTE.

FURNACE, *melting*. See *Wind* FURNACE.

FURNACE, *plumbers*, is of three kinds: in the firſt they melt the lead, whereof ſheets are to be caſt.

This is only a kind of large copper, or receptacle like a copper, made of free-ſtone, and coated well round with potters clay, having a little iron pan at bottom.

In the ſecond they melt the lead to be caſt in moulds for pipes, &c. which are not to be ſoldered.

The third is the tinning *furnace*, which is a ſquare frame of wood, or ſometimes a maſs of ſtone-work with a brick hearth, whereon is made a charcoal fire, which ſerves them for the applying of thin tin leaves on the works. See PLUMBERY.

FURNACES *for baking and burning porcelain, or China ware*. See PORCELAIN.

FURNACES, *portable*, are thoſe, which, with regard to their ſize, and the facility and moderate charge of their conſtruction, are peculiarly adapted to experimental enquiries. The term *portable*, when applied to *furnaces* more generally, and in oppoſition to *fixed*, has been already explained. Under this head we ſhall now give an account of Dr. Lewis's ingenious contrivance for the conſtruction of ſuch *furnaces*. For this purpoſe he makes uſe of the black lead crucibles, of the ſize marked No. 6, the dimenſions of which are about twelve inches high in the inſide, near eight inches wide at the mouth, and about the middle of their height ſix and a half. Each crucible has its mouth ground ſmooth and flat, upon a ſtone, with a little ſand; and a round hole ſawed in its bottom with the common compaſs ſaw of the carpenters. In the ſide, a little above the bottom, another round hole is made, and oppoſite to this a ſquare one; above which is cut a larger ſquare one. See *fig.* 42. A. All the apertures are fitted with ſtoppers, cut out of pieces of broken crucibles; the ſquare apertures are made little narrower internally than externally, at each of their ſides, ſo that the ſtoppers, whoſe outward ſurface is even with that of the outſide of the pot, can neither be puſhed inwards, nor fall out, when the pot ſtands on either end. The round ſtoppers are made to fit cloſe, by grinding them into the apertures; and they are taken out with a kind of fork, the points of which are introduced into two ſmall holes in each ſtopper, and at the ſame diſtance from one another in all of them. The grate for this *furnace* conſiſts of an iron ring, with croſs bars fixed in it. See *fig.* 42. B. Three of theſe grates of different widths, are required for different uſes: one of which is made to reſt againſt the converging ſides of the pot, in the lower narrow part, juſt above the lowermoſt ſquare hole; another ſo large that it may enter no farther than nearly to the top of the uppermoſt hole; and the third of the ſame width with the outſide of the mouth of the crucible. The lower and middle grates are ſupported either by grooves round the pot, or by pins in their circumference, reſting on notches within the pot. A grate might be made for theſe *furnaces* of four or five iron rings, placed within one another, each of which ſhould be furniſhed with three pins at equal diſtances, projecting from its circumference; and the pins of the inner ring ſhould be contrived to drop down into correſponding notches made in the next, and the pins of the ſecond rings into notches in the third; the notches being made in the middle of the ſpaces between every two pins. A grate of this kind, being compoſed of moveable parts, may be enlarged or diminiſhed at pleaſure, ſo as to fit *furnaces* of different widths, by adding or removing a ring on the outſide.

In order to render the *furnaces* ſufficiently durable, they are bound round in three or four different parts, with copper-wire, about the ſize of a crow quill, and made pliable by heating it on live coals, ſo as not to interfere with the doors or holes; or they may be ſurrounded by iron

iron or copper hoops, instead of wire. In either case the mouth is effectually secured by a thin copper hoop, which prevents the edges from breaking or wearing; and the small space left between the furnace and the upper edge of the hoop is filled with a little moist loam, or with clay mixed with powdered pots. The inside of the *furnace* should be washed over with Stourbridge clay, diluted in water; and when it is designed for continued strong fire, or for bearing the action of corrosive bodies, it should be lined to some thickness with a lute, composed of Stourbridge clay, beaten up with about twice its measure of coarse sand, or of glass-house pots, in coarse powder. The handle of these *furnaces* is made of an iron rod, or strong iron wire, about three feet long, bent like the bale of a pail to the width of the *furnace*, and fastened in two opposite holes made in the *furnace* through the copper hoop.

Besides the black-lead crucibles, which make the body of the *furnace*, there are required a foot for them to stand upon, a chimney, and an iron hoop. The best sort of foot is a flat, heavy, iron ring, with three legs five or six inches high, in one of which is a screw for raising or lowering it, so that the *furnace* may be made to stand level on an uneven floor. A foot may also be formed of an inverted crucible, by making an aperture in the bottom, and sawing three arches at equal distances in the sides, so as to leave between them legs of sufficient strength; or an inverted *furnace* will answer the purpose. The ashes that fall down are received in an iron pan, placed underneath.

The chimney is composed of three pipes of forged iron plate, not less than one eighth of an inch thick; and each of the pipes is a foot and a half, or two feet long. The lowest pipe is encompassed with a heavy ring about an inch above its lower end, which enters into the hole in the top of the inverted pot, in order to keep it steady: the upper end of the second pipe is received into the lower end of the next, and the end of this is in the same manner received by the third. The upper end of the chimney is made square, that it may fit into the larger door of the furnace, and serve occasionally as a lateral chimney.

The hoop is formed of a forged iron plate, not less than one sixteenth of an inch thick, turned round and welded together at the ends. See a perpendicular section of it, *fig.* 42. C. It is about six inches deep, and of the same width externally with the top of the *furnaces*, but its thickness being less than that of the *furnaces*, it is internally wider. One end of this hollow cylinder has an iron ring passing round it within side, and on this end it commonly stands upon the mouth of one of the pots: near this end is a semicircular aperture, whose door is rivetted on a large iron plate, which opens downwards on hinges, and drops no lower than to a horizontal situation. See *fig.* 42. D.

One of the black lead crucibles prepared in the manner above described, with the lower small grate introduced into it, is a *furnace* for open fire; the lower square aperture under the grate is the door of the ash-pit, and the upper one above the grate is a door to the fire-place. The fuel, which is always charcoal, is put in at the top, and is supplied with air through the apertures beneath the grate; by closing or opening which, the fire is diminished or increased.

By introducing into the open *furnaces* an iron pot, empty, or containing sand, this becomes a *furnace* for a *capella vitrea*, or sand *furnace*, in which case the fuel is put in through the fire-place door.

Farther, a vessel broader than the *furnace* may be placed on the top, with three iron supporters under it, to procure a space for the passage of the air. The flat iron pan used on other occasions for receiving the ashes, may be employed in this manner as a vessel for calcinations, for the evaporation of solutions of lixivial salts, &c. For vessels of a deeper kind, as a copper still, the capacity of the *furnace* is increased by placing over it the iron hoop, by which it is enabled to receive the body of a still, of a size sufficient for the purposes of an experimental laboratory. See STILL.

If one pot be inverted over the other, with the iron hoop between them, we shall have a *furnace* for cupellation, calcination under a muffle, and the other purposes of that which is called the *assay* FURNACE; and also for experiments of enamelling, of baking colours on earthenware and glass, &c. The chimney, or a part of it, may be occasionally set upon the top, for raising the fire when it proves too languid. The same combination of the two pots and hoop will serve as a *reverberatory*, for distillation in coated glass retorts, earthen retorts, or long necks, provided that the middle grate be introduced into the undermost pot, and two iron bars are laid across in its upper part, to support the distilling vessel, whilst its neck comes out at the door of the hoop. The *reverberatory* and *assay* FURNACES are, in reality no other than the *round* FURNACE, with a muffle or a retort in the fire instead of a crucible.

Furnaces of this kind may be used as a common stove, for keeping a room warm with a small quantity of fuel. For this purpose the small grate is introduced into the lower part of the undermost pot, the fire-place door is closed, and the ash-pit door, or bottom hole left open for admitting air. It is then charged with small pieces of charcoal with lighted coals thrown above them, its top is covered by the largest of the grates, on which is placed the hoop and dome, filled with balls of baked earth, or with pieces of brick, so disposed as to leave small vacities between them. When the stove is placed in the middle of a room, its injurious air may be carried off by a pipe inserted laterally into the larger door of the dome, and communicating at the other end, which should be raised eight or ten inches, with the chimney of the room; and all other apertures of the dome should be closed. The *furnace*, thus charged, will keep up a moderate, and nearly equal warmth for many hours, without injury or offence. See *fig* 43. See *Bellows* FURNACE and *Wind* FURNACE. See also LABORATORY.

FURNACE, *reverberating*, or *reverboratory*, is a simple *furnace*, the fire-place of which is covered with a piece of the same diameter and form as the *furnace*, which is generally cylindrical. This piece is crossed in its lower part by two bars of iron placed horizontally and parallel to each other, and at its upper edge it has a semi-circular cut. This piece forms a third cavity, which is called the laboratory, because it is intended to receive the retorts, containing the matter to be distilled. The semi-circular cut is made to give passage to the neck of the retort, which ought to be inclined at an angle of forty five degrees. The two bars at the bottom of the laboratory are designed to support the vessel placed there. Above the piece last described, there is placed a fourth piece, in the form of a spherical cap, or an inverted dome, of equal diameter with that of the other piece to which it is fitted; in its lower edge there is a semicircular cut, corresponding with that of the lower piece: and these together form a circular opening; the dome has in its top another opening, or short tube, through which the air contained in the *furnace* passes, and serving for a kind of chimney. The use of the dome is to keep the heat all round the retort, and to apply a certain degree of heat to the upper part or vault of the retort, by reflecting or reverberating it; whence it is called a *reverberatory*. In consequence of this disposition, the vapours which rise in the retort are determined more efficaciously to pass through its neck. Reverberatory *furnaces* are used for distillations with a retort, in which a certain degree of heat is necessary; and distillation may be performed in them either in naked fire, by placing the retort immediately on the bars, or in a sand bath, by placing on these bars an iron vessel, with a semi-circular cut in its upper edge, containing fine sand to the thickness of one or two fingers; then the retort is placed in the vessel, and it is to be filled with sand up to the arch of the retort: See *fig* 44, in which *a* represents the ash-hole door; *b* the fire-place door; *c*, *c*, *c*, the registers; *d*, the dome or reverberatory; *e*, the conical funnel; *f*, the retort in the *furnace*; *g*, the receiver; and *h*, *h*, the iron bars for sustaining the retort.

FURNACE, *simple*, is a kind of hollow tower, cylindrical or prismatical, with two doors, or principal openings; the one below, called the door of the ash-hole, and the other immediately above this, called the door of the fire-place. Between these two doors a grate is placed horizontally across the interior part of the *furnace*, dividing its whole cavity into two parts, the lower part being called the ash-hole, because it receives the ashes which fall from the fire-place. The door of the ash-hole gives admittance to the air for maintaining the fire within the *furnace*. The upper cavity is called the fire-place, because it contains the combustible matters; and fresh fuel is introduced through the door of the fire-place.

This *furnace* is sufficient for many chemical operations: in the first place, amidst the coals, crucibles may be placed for the fusion of fusible materials, as lead, tin, bismuth, &c. or for the calcination of matters which require but little heat for their calcination, such as the alkali for making Prussian blue, bezoar mineral, &c. Or this *furnace* may also be placed bafons for evaporation, alembics for distilling in the water-bath, pots filled with sand for digestions and distillations to be performed by means of a sand bath and a gentle heat, either with alembics or retorts. For operations requiring a longer duration, this *furnace* is formed into an ATHANOR. See FURNACE, called *Athanor*. Macquer's Chem. Dict. Eng. edit.

FURNACES, *smelting*. See ORES and SMELTING.

FURNACE, *wind*, is the second *furnace* used in the fusion of metals for coinage. At bottom it has a hearth made hollow, in manner of a cupel, with a vent-hole in the fore-part thereof; over the vent-hole is a grate fealed in the maſſive of the *furnace*; over the grate is the place for the crucible, which is uſually of forged iron.

The fire being lighted, the crucible is ſet in, with a cover over it; and a capital, or cover of earth or iron, is laid likewiſe over the *furnace*; and at the top of this capital is a hole, five or ſix inches in diameter.

It is called *wind-furnace*, becauſe the air, entering through the vent-hole at bottom, which is always open, ſerves the ſame purpoſe as the bellows in other *furnaces*.

Gold is uſually melted in the bellows-*furnace*, as requiring an intenſer heat before it fuſes. Silver and copper are commonly melted by the *wind-furnace*.

Cramer, in his Art of Aſſaying Metals, gives the following account of the conſtruction and uſes of the *wind* or *melting-furnace*: it is formed of iron plates, the inner ſurfaces of which are covered with lute. The cavity of it may be formed according to an elliptical mould. 1. Make an hollow elliplis, the foci twelve inches aſunder, and the ordinate five inches long; cut it off in both its foci, that it may aſſume the figure *fig.* 45. 2. Then make in this hollow body, and near its lower aperture, four holes, eight lines in diameter, and directly oppoſite *c*, *c*. 3. Then faſten two flat iron rings *d*, almoſt one inch and a half broad, at both the upper and the lower inward edge of this oval cavity; and fill the inſide of it with ſmall iron hooks, jutting out about ſix lines, and three or four inches diſtant from each other. Theſe, together with the rings juſt mentioned, ſerve to faſten the lute. Thus will the body of the *furnace* be made: only you muſt add at the outſide two iron handles *e*, *e*, to be riveted on each ſide of it, that it may be taken hold of and moved. 4. Then make the cover of the furnace, which may be formed like the part cut off from the elliplis, ſee *fig.* 46. Let this have an opening *b* made in it, four inches high, five inches broad at bottom, and four inches at the top; and adapt to this an iron door hung on hinges to ſhut it cloſe, and having at the inſide a border faſtened to it, anſwering exactly to the circumference of the door, and as prominent inwardly as the thickneſs of the lute to be applied to it requires: for the ſame purpoſe, let ſmall iron hooks be faſtened to the inſide of the door, which is intercepted by the ſaid border. And leſt this cover ſhould be burnt within by the force of the fire, you muſt cover the inſide of it with the LUTE deſcribed under that article: therefore it muſt be likewiſe furniſhed with a ring and iron hooks to faſten the lute; as was ſaid before, when we ſpoke of the body of this *furnace*. Beſides this, you muſt faſten two iron handles, *fig.* 46. *e*, *e*, on the outſide of this cover. Then a round hole muſt be made in the top of it, being three inches in diameter, prolonged into a hollow tube *d* almoſt cylindrical, and a few inches high, upon which the iron funnel deſcribed may, in caſe of neceſſity, be put after the manner mentioned in the ſame place where we ſpoke of the aſſay-oven. 5. After this, the lining of both the body and cover of the *furnace* within is made in the ſame manner above deſcribed. Moreover, you muſt make for this *furnace* two moveable bottoms, viz. one to receive the aſhes, and admit the air; the other to ſerve for reductions. The firſt is made with an iron plate, formed into a hollow cylinder, open at top, and to be ſhut at bottom with an orbicular iron plate, as with a baſis, five inches high, and of ſuch a diameter, as that it may receive the inferior orifice of the body of the *furnace*, *fig.* 45. the depth of half an inch, ſee *fig.* 47. therefore let an iron ring *c*, half an inch broad, be faſtened on the inſide of the ſaid bottom, and at the diſtance of half an inch from its upper border, to ſupport the body of the *furnace* put into it. Again, let this bottom have a ſquare door, four inches high, and as many inches broad, that may be ſhut cloſely, with a door hung on hinges, that you may, by means of it, diminiſh or increaſe the drought of the air, and thus govern the fire at pleaſure. Then, on the left ſide of the door, and at about half the height of this bottom part, let a round hole *d* be made, one inch and a half in diameter, to admit the pipe of the bellows when need requires. Next to this, let another bottom part be made of the ſame matter and figure as the foregoing: let it likewiſe be of the ſame diameter, but two inches higher, ſo that it may be of the height of ſeven inches. Likewiſe let it have round it a like iron ring below its upper border, to ſupport the body of the *furnace* to be received in it. But let a hole two or three inches broad, and one inch high, *fig.* 48. *c*, be cut out juſt below the ring, in the ſide of this bottom part; then let another round hole be made in the left ſide of this firſt hole, fit to admit the pipe of the bellows *d*. Farther, let another round hole like the foregoing *c* be made on the right, and at the diſtance of one inch from the bottom: then let the whole inſide of this bottom part (the part above the ring excepted) be overlaid with lute, and a bed be made at the bottom, of a figure like that repreſented by the line *f*, *g*, *h*. The matter of which this is made is common lute pulveriſed, paſſed through a ſieve, and mixed with ſuch a quantity of duſt of charcoal [illegible] in the ſame manner, ſo that the mixture being moiſtened and preſſed down, may at leaſt be ſlightly [illegible] this matter preſſed on the bottom of the [illegible] part, a bed is made like the legment of a ſphere, having in the middle a ſmall cavity ſomewhat lower, and made extremely ſmooth, after the manner proper for large aſh veſſels or teſts.

This *furnace* is chiefly fit for fuſions, which may be made in it with and without veſſels. When you are to melt with a veſſel, put the body of the *furnace*, *fig.* 45. upon the firſt bottom, *fig.* 47. that has a door to it to open on hinges; introduce two iron bars through the holes of the *furnace*, *fig.* 45. *c*, *c*; put upon them the iron grate, which you are to introduce through the upper mouth of the *furnace*: then put in the middle of this grate a brick or ſquare tile, very ſmooth every where, warmed, and perfectly dry: otherwiſe, the veſſels put upon it, eſpecially the large ones, are eaſily ſplit by the moiſt vapours coming out of it in the operations. Let the height and width of this ſtone be a ſmall matter broader and higher than the bottom of the crucible or pot to be ſet upon it; for if it were leſs high, the bottom of the veſſel could not be ſufficiently warmed; and if it were leſs broad, the veſſel might eaſily fall from it: then put upon this tile the veſſel containing the matter to be melted, and ſurround it immediately with coals on every ſide, which muſt be ranged according to the method preſcribed before, in our deſcription of the *aſſay-furnace*: then you govern the fire, by opening and ſhutting the door of the aſh-hole, *fig.* 47. *b*: you excite it by putting the cover, *fig.* 46. upon the body of the *furnace*; and if, beſides, you put a funnel upon the cylindrical mouth of this cover, the melting fire becomes ſtill more violent: but if you moreover introduce the bellows through the hole of the bottom part, *fig.* 47. *d*; and the joint [illegible] *nace* with the bottom part, and the door of the [illegible] unleſs it can be ſhut very cloſe, being exactly ſtopt with thin lute, or Windſor loam, the fire thus [illegible] by the blaſt of the bellows is carried to the higheſt degree, and far ſurpaſſes that which may be made in a ſmith's forge. Another advantage of this method is, that the veſſels are not ſo eaſily broken, becauſe the blowing of the bellows cannot affect them immediately, and becauſe a fire perfectly equal is excited on every ſide. One may eaſily examine with this apparatus, how ſtones are affected by the violence of the fire only. Now, if you have a mind to perform any operation without a veſſel, and with a naked fire; for inſtance, to melt and reduce the calces or ſcoriæ of copper, tin, lead, and iron, or the ores of theſe metals; the body of the *furnace* muſt be put upon the other pedeſtal, having a bed in it, *fig.* 48. However, you muſt, before this, open with a knife the oblong hole *c*, and the round one *d* of this bottom part, which are ſtopped with the lute ſticking to the inſide: then you apply at the round hole *d* on the left ſide the bellows, in ſuch manner that the nozzle of it, being directed obliquely downwards, may blow ſtrongly againſt the bed *f*, *g*, *b*: by this means, all the aſhes that fall into the bed are blown away, and the ſtrength of the fire determined to ſuch a degree, that all the melted bodies that fall into the ſaid bed remain in their ſtate of fuſion; and were it otherwiſe, the melted bodies would immediately wax cold, and adhere in grains to the bed, whereas they ought to have melted into one regulus. The oblong hole in the fore-part of this bottom part *c*, ſerves to diſcover, by means of a poker, whether the matter in the bed be melted or not: it ſerves likewiſe to take away through it whatever might ſtop the bellows, and, in ſome caſes, to take away the ſcoria: then you put firſt coals into the *furnace* one ſpan high, and blow them well with the bellows, to make them burn, that the bed may be very hot before the matter to be melted is put into it; for if this is not previouſly done, the melted mals ſeldom runs into a regulus, but remains diſperſed among the ſcoriæ, which ſoon grow hard. The bed being well heated, and freſh coals added to the fire, put into it ſuch a quantity of the matter to be melted as cannot hinder the fire from being carried to the requiſite degree; which cannot be determined otherwiſe than by experience: again, put freſh coals, and upon them another quantity of the matter to be melted; they may be, like ſteps, one upon another: but if the maſs, once melted, could not long ſuſtain the ſtrength of the fire, or if you had a mind to melt a greater

quantity

quantity of matter than what can be contained in the bed, you muſt open the round lower hole, *fig.* 48. *r.* that you may make a channel paſſing from that hole through the lute, and reaching to the ſmall cavity at the bottom of the bed *c*: to this hole, at the outſide, apply an earthen diſh like the bed within, or any proper recipient, ſurrounded with burning coals, into which the matter melted running from the bed through the hole, *fig.* 48. *r.* may be collected, as repreſented by *fig.* 49.

With regard to the elliptic or parabolic figure of the ſides and dome of a *furnace*, we may obſerve, that many have recommended this form of conſtruction, expecting that the rays of fire, ſtriking all over the internal ſurface, would be reflected back into a ſmall-ſocal ſpace, in the ſame manner as the ſolar rays are concentrated by burning concave ſpecula. An elliptic *furnace* was prepared with great care by Dr. Lewis; but he was much diſappointed in its effects; for he could not find, that any focal reflection obtained in it, or that any advantage reſulted from the exactneſs of its figuration, or from the preciſe ſpecies of its curvature. Com. Phil. Techn. p. 26.

The *melting furnace* uſed in the manufacture of braſs is in the form of the fruſtum of a hollow cone. At the bottom of the *furnace*, or greater baſis of the fruſtum, is a circular grate, or iron plate, which is covered with a coat of clay and horſe-dung, to defend it from the action of the fire, and pierced with holes, through which the air, maintaining the fire, paſſes. The crucibles, filled with the proper materials (ſee BRASS), ſtand upon the circular plate, forming a circular row with one in the middle. The fuel is placed betwixt the crucibles, and is thrown into the *furnace* at the upper part of it, or the leſſer baſis of the fruſtum, in which is fitted a cover made of bricks or clay, kept together by bars of iron, and pierced with holes. This cover ſerves as a regiſter; when the heat is to be increaſed, the cover is partly or entirely taken off, and a free draught is permitted to the external air, which paſſes along a vault under-ground to the aſh-hole, through the holes in the circular grate or plate, betwixt the crucibles, and through the upper mouth, along with the ſmoke and flame, into an area, where the workmen ſtand, which is covered with a large dome or chimney, through which the ſmoke and air paſſes. When the heat is to be diminiſhed, the mouth of the *furnace* is cloſed with the lid, through the holes of which the air, ſmoke, and flame paſs. The crucibles are to be kept red-hot during eight or ten hours, and in ſome places much longer, even for ſeveral days, according to the quality of the calamine; during which time the zinc riſes in vapour from the calamine, unites with the copper, and renders that metal fuſible by conſiderably leſs heat than it is alone. To render the metal very fluid, that it may flow into one uniform maſs at the bottom, the fire is to be increaſed a little before the crucibles are taken out, for pouring the fluid metal into moulds. By this proceſs, ſixty pounds of braſs may be obtained from ſixty pounds of good calamine, and forty pounds of copper, though a conſiderable quantity of zinc is burnt and diſſipated during the operation; but leſs of this vapour eſcapes by uſing granulated copper. See GRANULATION. Macquer's Chem. Dict. Eng. ed. note, under BRASS.

Dr. Lewis, in his apparatus of portable *furnaces*, conſtructs a wind *furnace*, for the fuſion of metals, the aſſaying of ores, and ſimilar operations, by inverting one pot over the other, and placing on the top either the entire chimney, deſcribed under *portable* FURNACES, or two, or one of its pipes, according to the degree of fire which is required. The ſecond fixed grate is preferable to the ſmaller one, becauſe it has more interſtices for admitting air to the fuel. The crucible, containing the materials for operation, is placed on a circular ſlip of brick, or of a broken pot, a little wider than its bottom, laid on the middle of the grate, to prevent the impact of the cold air. The charcoal is put in through the fire-place door, or larger aperture of the dome, or upper pot, which ſhould always be cloſed after each ſupply of fuel. The *furnace* ſtands on its trivet, or open foot, with the flat iron pan underneath, which ſerves to receive the aſhes, and to preſerve the fluid contents of the crucible, if it ſhould happen to fail, during the fuſion. The two oppoſite holes in the upper part of the dome afford the conveniency of paſſing an iron rod through, for ſafely lifting it when intenſely heated. See *fig.* 50. This *furnace* may be eaſily converted into a blaſt *furnace*, by introducing the nole of a pair of double bellows into the round hole in its ſide; in which caſe, all the other apertures beneath the grate muſt be cloſed, while the bellows acts, that the air forced in by it may be prevented from eſcaping.

A ſtronger wind *furnace*, capable of bearing a long continuance of vehement fire, may be conſtructed of two large pots; the lowermoſt of which has only a round hole in the bottom for admitting air; and the upper one, or dome, a ſimilar hole, correſponding to the chimney, with a door in the ſide, through which the fuel is put in. The *furnace* is placed upon an inverted pot, which has a hole in its top anſwering to that in the bottom of the *furnace*, another large one in its ſide, and its mouth ground ſmooth, that it may apply itſelf every where cloſe upon the flat ſtone, or iron plate, which ſerves as a ſtand for it. Into the ſide aperture of this lower pot, which is both the foot and aſh-pit of the *furnace*, an iron pipe is inſerted, ſomewhat wider than the wideſt part of the chimney, and two or three feet long, on the end of which may be fitted a wooden one of more conſiderable length. The whole of this pipe may be laid horizontal, ſo as to reach into an adjoining apartment; or rather, if there is a conveniency, the wooden pipe may be ſunk perpendicularly through the floor into a room underneath, and the horizontal iron one joined laterally to it at the top; its uſe is for conveying into the *furnace*, inſtead of the adjacent air rarefied by the heat, the colder and denſer air at a diſtance; and its effect in animating the fire will be in proportion to the coldneſs and denſeneſs of the air to which it reaches.

This *furnace* is repreſented in *fig.* 51. The pipe of a bellows may be adapted to a hole made in the ſide of the foot, or aſh-pit, of this *furnace*, for producing a more vehement fire; and the air-pipe is at the ſame time ſtopped by means of a moveable regiſter in the end next the *furnace*. This regiſter is a circular iron plate, fixed on an axis, which is placed acroſs the pipe; the extremity of the axis projecting on the outſide, the plate is thereby readily turned, ſo as either to allow a free paſſage for the air, or to cloſe the whole bore of the pipe. Lewis's Com. Phil. Techn. p. 11. 24, &c.

FURNACE *of a mine*, in the *Art of War*. See CHAMBER and MINE.

FURNAGE. See FORNAGE.

FURNITURE, in *Dialling*, certain additional points and lines drawn on a dial, by way of ornament.

Such are the ſigns of the zodiac, length of days, parallels of declination, azimuths, meridians of the principal cities, Babyloniſc and Italian hours, points of the compaſs, &c. See DIAL.

For drawing *furniture* on dials, the ANALEMMA, or trigon of ſigns, is an inſtrument of principal uſe.

FURO, in *Zoology*, a name given by ſome authors to the FERRET, called by others alſo *furunculus* and *iſtis*.

FUROR *uterinus*, a ſpecies of madneſs, peculiar to women, exciting them to a vehement deſire of venery, and rendering them inſatiate therewith, and manifeſting itſelf by obſcene ſpeech and wanton behaviour. As the diſorder increaſes, the patient ſcolds, laughs, and cries by turns. The immediate cauſes of the diſeaſe are an inflammation, tenſeneſs, and irritability of the uterus and pudenda of women, and particularly of the clitoris and vagina, in which the venereal ſtimulus reſides, or the too great abundance and acrimony of the humours of theſe parts. In order to the cure, which, if the diſorder be taken in time, may be expected, the patient ſhould be bled in proportion to her ſtrength. Camphor, in doſes of fifteen or twenty grains, with nitre, and ſmall doſes of the Thebaic tincture, may be repeated at proper intervals. Some preſcribe the ſal. ſaturn. in doſes of three to five grains. Beſides bleeding, cooling purges ſhould alſo be repeated in proportion to the violence of the ſymptoms, &c. What is uſeful in maniac and hypochondriac diſorders, is alſo proper in this caſe, regard being had to the conſtitution and habit of the patient. Injections of barley water, with a ſmall quantity of hemlock juice, may be frequently thrown up into the uterus, and theſe have been much recommended.

FURR, or FUR, in *Commerce*, the ſkins of divers kinds of wild beaſts, dreſſed with the hair on; to be uſed as a lining, or doubling, of garments, robes, &c. either for warmth, ornament, or diſtinction of rank and dignity.

The word is formed of the French *fourrure*, a *lining*; which Du-Cange derives from *furura*, uſed, in the barbarous Latin, for the ſame thing. We alſo meet with *foruratus*, *foderata*, *fodratus*, and *fodraturæ*, in the ſame ſenſe.

The robes of kings, dukes, and peers, are lined with divers kinds of *furrs*, and, in particular, ermine, to render them more magnificent.

The ſame may be obſerved of ſeveral chief magiſtrates, judges, and doctors of different faculties, in the univerſities.

The kinds of *furrs*, or ſkins, chiefly dreſſed in alum, and with the hair on, are thoſe of the ermine, fables, ſquirrel, coney, caſtor, otter, dog, fox, wolf, tiger, bear, &c. The ſtatute 28 Hen. VIII. cap. 13. mentions divers kinds of *furr*, viz. *fables*, which are a rich *furr*, of colour be-

tween black and brown, the skin of a beast called a fable, in bignefs between a pole-cat and an ordinary cat, bred in Ruſſia and Tartary; *ſacarus*, the ſkin of a beaſt of that name, nearly the ſize of a *mole*, in colour neither red nor brown, but between both, mingled with black ſpots; they are bred in Muſcovy, and their ſkins are a very rich *fur*; *genetta*, a beaſt's ſkin ſo called, in ſize between a cat and a weazle, muſked like a cat, and of that nature; they are of two kinds, black and grey; the black is moſt precious, which hath black ſpots upon it, hardly to be ſeen; this beaſt is the product of Spain; *foina*, which are of Pythias like the fable, the top of the *fur* black, and the ground whitiſh, bred for the moſt part in France; the *marten*, a beaſt very like the fable, the ſkin ſomething coarſer, produced in England and Ireland, and all countries not too cold; but the beſt are from Ireland. Beſide theſe, there are the *ſtink* and *polecat*; the *ſcholar*, a little beaſt in ſize near the ſquirrel; *manivet*, being the bellies of ſquirrels; and *ſhanks*, or what is called *budge*, &c. all of them *furrs* of foreign countries; ſome whereof make a large branch of their inland traffic.

FURRS, *timber of*. See TIMBER.

FUR, in *Heraldry*, a repreſentation of the ſkins of certain wild beaſts, worn, both in the doublings of the mantles of coat-armour, and in the armour itſelf.

The heralds uſe two metals, five colours, and two *furrs*, or hairy ſkins; viz. ermine and vair.

The origin of theſe *furrs* Mackenzy aſcribes to the ſhield's being anciently covered with ſkins; which ſkins, or coverings, were afterwards repreſented in the ſhields; a more probable derivation, in our opinion, than to ſay they were placed on ſhields, becauſe they had been worn in mantles and garments.

Furrs either conſiſt of one colour, which is white; or more than one; and thoſe either two, or more than two.

Furrs of two colours are either ermine, being white with black ſpots; erminois, black with white ſpots; erminois, whoſe ground is yellow, and the powdering black; or pean, which is black powdered with yellow.

Furrs of more than two colours are called VAIR, and VAIRY.

FURRIER, a perſon who trades, or works, in *furrs*, or lines robes, &c. therewith.

FURRING *of a ſhip*, is laying on double planks on her ſides.

This is done after the ſhip is built, and is by the ſailors called *plank upon plank*: But there is another way of *furring*, which is more properly ſo called; and that is, when a ſhip's planks are ripped, and new timbers are put on the former timbers, and on them other planks; which is done ſometimes to make a ſhip bear the ſails the better.

FURRINGS, or FURRS, in *Architecture*, the making good of the rafter-feet in the cornice.

When rafters are cut with a knee, theſe *furrings* are pieces which go from along with the rafter, from the top of the knee to the cornice.

When rafters are rotten, or ſunk hollow in the middle, there are pieces cut the ſame bulk in the middle, and tapering towards each end, which are nailed upon them to make them ſtraight. Such pieces are called *furrs*; and the putting them on is called *furring* the rafters.

FURROW, among *Gardeners*, denotes a ridge or ſwelling on the ſide of a tree, ſtalk, or fruit.

FURROW is alſo uſed for the deep trench left between ridges, to drain off the ſuperfluous manſture.

FURUNCULUS, in *Surgery*. See BOIL.

FURUNCULUS, in *Zoology*, the name given by many authors to the FERRET, called alſo the *furo* and *itetis*.

FURZE, GORSE, or WHINS, *Ulex*, in *Botany*, a genus of the *dindynamia decandria* claſs. Its characters are theſe: the flower has a two-leaved empalement, is of the butterfly kind, and has five petals; the ſtandard is large, erect, oval, heart-ſhaped, and indented at the point; the wings are ſhorter and obtuſe; the keel is compoſed of two obtuſe petals, whoſe borders are joined at the bottom. It has ten ſtamina, nine joined, and one ſeparate, terminated by ſingle ſummits; with an oblong cylindrical germen ſupporting a ſtring ſtyle, crowned by a ſmall obtuſe ſtigma; the germen afterward turns to an oblong turgid pod, with one cell, opening with two valves, incloſing a row of kidney-ſhaped ſeeds. There are two ſpecies, the common one of which is too well known to need deſcription.

Theſe plants propagate themſelves very plentifully by ſeeds; for as the ſeeds ripen, the pods open with the warmth of the ſun, and the ſeeds are caſt out by an elaſtic ſpring to a great diſtance all around; where they ſoon vegetate, and are not eaſily deſtroyed when well rooted. Some years ago the ſeeds of this plant were ſown to form hedges about fields; where, if the ſoil was light, the plants ſoon became ſtrong enough for a defence againſt cattle; but as the hedges in a few years became naked at the bottom, and ſome of the plants frequently failed, which made gaps in the FENCE, this method has of late been diſuſed. But ſome perſons who have ſown the ſeeds of this plant upon very poor, hungry, graveliſh, or ſandy land, have reaped more profit than they could make of the ground by another crop, eſpecially in places where fuel is dear; where this *furze* is frequently uſed for heating ovens, drying malt, and burning lime and bricks. Miller.

The tops of *furze* bruiſed, in order to take off their ſharp points, have lately been found to be excellent food for cattle, particularly for horſes. Thoſe that have been lean and ſickly have often recovered, and plumped up in a ſhort time, by the uſe of this fodder. When *furze* is raiſed for this purpoſe, the ſeeds ſhould be ſown in February, March, or April, on ground previouſly prepared, as for barley, and afterwards barely covered over. Six pounds of ſeed will be ſufficient for an acre; the young plants muſt be preſerved from cattle during the firſt year, and in the next they will be fit for cutting; which may be begun in October. The plants will continue to ſhoot till Chriſtmas, and be fit for uſe till March. It is ſaid, that an acre of ground will produce fifteen tons of this fodder; and that it will anſwer the ſame purpoſe as an equal quantity of hay. In ſome places there are mills for bruiſing it; and it is mixed with chopped ſtraw in the proportion of an hundred of ſtraw to a ton of *furze*. It is ſaid, that the common Engliſh *furze* will grow upon the dry ſands, that are in the neighbourhood of the ſea, though ſubject to be waſhed ſometimes by the water; this is a thing extremely worth the trying, as it would then be of the greateſt advantage to thoſe who have walls or banks near the ſea, to plant it on them to preſerve them.

This being a very unprofitable plant in reſpect of many others, it is often neceſſary to deſtroy it. This may be done by plowing and horſing the buſhes upon the land. Marling the land well in countries where marle is plentiful, is alſo a very good way; and there is yet another much better, which is to make wood-land, not arable, of the place; to this purpoſe it is only neceſſary to ſow or plant acorns at proper diſtances. The *furze* will ſhelter the acorns till the time of their growing to two or three feet high, and then they will ſoon grow and deſtroy all the *furze* and every other weed. Lawrence's Huſbandry, p. 308.

FUSA, in the *Italian Muſic*, the name of one of the muſical notes, frequently alſo called CHROMA, and by us QUAVER.

FUSANUS, in *Botany*, a name given by many authors to the ſhrub, more uſually called *euonymus*. See SPINDLE-*tree*. This was ſometimes called *citroſclis* by the Greeks, and hath both this and its Roman name *fuſanus*, from its being of uſe for making the diſtaff, uſed by the women in ſpinning. Some have ſuppoſed that this was the ſame with the *euonymus*, *hamnus*, of Theophraſtus and the Greek writers, but very erroneouſly. See TETRAGYNIA DECANDRIA.

FUSAROLE, in *Architecture*, a moulding, or ornament, placed immediately under the echinus, in the Doric, Ionic, and Compoſite, capitals.

The Italians call it *ſuſcinto*, and the French, from whom we borrow it, *fuſarole*.

The *fuſarole* is a round member, carved, in manner of a collar, or chaplet, with oval beads. The *fuſarole* ſhould always anſwer exactly under the eye of the volute, in the Ionic capital.

FUSEE, or FUSY, in *Watch-work*, is that conical part, drawn by the ſpring, and about which the chain, or ſtring, is wound.

The word is French; where it literally ſignifies a *ſpindle*.

The ſpring of a watch is the firſt mover. It is rolled up in a cylindrical box, againſt which it acts, and which it turns round in unbending itſelf. The ſtring, or little chain, which at one end is wound about the *fuſee*, and at the other faſtened to the ſpring-box, diſengages itſelf from the *fuſee*, in proportion as the box is turned. And hence the motion of all the other parts of the ſpring-watch.

Now the effort, or action, of the ſpring, is continually diminiſhing from firſt to laſt: and, of conſequence, unleſs that inequality was rectified, it would draw the ſtring with more force, and wind a greater quantity of it upon the box at one time than another; ſo that the movement would never keep equal time.

To correct this irregularity of the ſpring, nothing could be more happily contrived than to have the ſpring applied to the arms of levers which are continually longer as the force of the ſpring is weaker. This foreign aſſiſtance, always increaſing as it is moſt needed, maintains the action and effect of the ſpring in an equality.

It is for this reaſon that the *fuſee* is made of a conical figure. Its axis, which is immovable, is the ſeries of the centres of all the unequal circumferences which compoſe the

the ſurface of the *fuſee*: according as the part of a ſtring, which is untwiſting, is applied to a larger circumference, it is at a greater diſtance from the fixed point in the axis correſponding thereto; and, of conſequence, the power which draws by this ſtring, viz. the ſpring, acts with the more advantage; the ſpring begins to draw from the vertex of the cone, the moſt diſadvantageous part, becauſe its own force is then the greateſt.

If the action of the ſpring diminiſhed equally, as the parallel baſes of a triangle do; the cone, which is generated of a triangle, would be the preciſe figure required for the *fuſee*: but, it is certain, the weakening of the ſpring is not in that proportion; and, of conſequence, the *fuſee* ſhould not be conical.

In effect, experience ſhews, that it ſhould not be ſtrictly ſo; but that it be a little hollow toward the middle, i. e. the arm of the lever muſt be there a little ſhortened; becauſe the action of the ſpring is not ſufficiently diminiſhed of itſelf.

It is a matter of enquiry, among geometricians, what the preciſe figure of the *fuſee* ſhould be; that is, what the curve is, by whoſe revolution round its axis, the ſolid, whoſe figure the *fuſee* is to have, ſhall be produced. M. Varignon has determined this curve. The axis of the *fuſee* is alſo the axis of the curve, which is convex on the ſide toward the axis, and, of conſequence, concave all the way on the other, or outer ſide; and the ordinates are the different diſtances at which the ſtring is to be with regard to all the ſucceſſive fixed points of the axis.

The force of the ſpring multiplied by the arm of the lever it is applied to, each moment, being always to make an equal product; it follows, that when the ſolid of the curve ſhall be formed, an ordinate multiplied by the ſurface of the ſolid compriſed between that ordinate and the greateſt of all the ordinates, viz. that of the baſe, will always yield a product equal to that of any other ordinates multiplied in the ſame manner. For the ordinates are only arms of the lever; and the parts of the ſurface comprehended between them and the baſe are equal to the lengths of the ſtring which covers them, i. e. to the correſpondent forces of the ſpring; which is what conſtitutes the equation and the eſſence of the curve.

FUSEE, FUZE, or FUSE, in *War*, an appendage of a bomb or granade-ſhell, by which the powder, or compoſition, in the ſhell, is ſet on fire, to do the deſigned execution. The word is French, and literally denotes a *ſpindle*.

The *fuze* is a wooden pipe, or tap, commonly made of dry beach-wood, and ſometimes of horn-beam taken near the root, filled with wild-fire, or the like compoſition; and is deſigned to burn ſo long, and no longer, as is the time of the motion of the bomb or ſhell from the mouth of the mortar to the place where it is to fall, ſo that the *fuſee* muſt be contrived, either from the nature of the compoſition, or the length of the pipe which contains it to burn juſt that time. *Fuzes* are turned rough and bored at firſt, and then kept for ſeveral years in a dry place; the diameter of the hole is about a quarter of an inch, which does not go quite through, but leaves about a quarter of an inch at the bottom, and the head is made hollow in the form of a bowl. The compoſition for *fuzes* is ſalt-petre three parts, ſulphur one, and mealed powder three, four, and ſometimes five, when it is required to burn quicker. This compoſition is drove in with an iron driver, whoſe ends are capped with copper to prevent it from taking fire, and as equally hard as poſſible; the laſt ſhovel-full being all mealed powder, and two ſtrands of quick-match laid acroſs each other are drove in with it, the ends of which are folded up into the bowl, and a cap of parchment is tied over it till it is uſed. When theſe *fuzes* are drove into the loaded ſhell, the lower end is cut off in a ſlope, ſo that the compoſition may ſet fire to the powder in the ſhell, and they muſt have ſuch a length as to burſt nearly as ſoon as the ſhell touches the ground. When the diſtance of the battery from the object is known, the time of the ſhell's flight may be computed nearly; which being known, the *fuze* may be cut accordingly, by burning two or three, and making uſe of a watch or a ſtring and weight for a pendulum, of ſuch a length as to vibrate ſeconds or any given parts of time. If the *fuzes* are to be kept for ſome time after they are drove, the top muſt be covered with a mixture of two parts of pitch, one of roſin, and three of bees wax; which will prevent any air from coming to the compoſition. Muller's Treat. of Artillery, p. 294, &c.

FUZEE OF FUSEE, is alſo ſometimes uſed to denote a FIRE-*lock*.

FUSIBILITY, that quality in metals, and minerals, which diſpoſes them for FUSION.

Gold is more *fuſible* than iron, or copper; but leſs ſo than ſilver, tin, and lead.

Borax is frequently mixed with metals, to render them more *fuſible*.

FUSIL, in *Heraldry*, by the French called *foſſe*, q. d. ſpindle, is a bearing of a rhomboidal figure, more ſlender than the lozenge; its upper and lower angles being more acute than the two middle ones. See *Tab. Heralds. fig.* 42.

FUSIL, in the *Military Art*. See FIRE-*lock*.

FUSILE *column*, and *marble*; ſee the ſubſtantives.

FUSILIERS, or FUZILEERS, in the *Military Art*, are ſoldiers armed like the reſt of the infantry, but wearing caps like the grenadiers, though ſomewhat ſhorter. Of theſe there are three regiments in the Engliſh ſervice; the royal regiment of Scotch *fuſiliers* raiſed in 1678; the royal regiment of Engliſh *fuſiliers* raiſed in 1685; and the royal regiment of Welch *fuſiliers* raiſed in 1688-9.

The word is formed from the French *fuſil*, a *fuſee*, fire-lock.

FUSILUS, in *Botany*, a name given by ſome to the TUSANUS, a more common name for the *cinnamon*.

FUSILY, or FUSILE, in *Heraldry*, is when a field, or ordinary, is entirely covered over, or divided into *foſils*.

FUSION, the ſolution, or melting, of metals, minerals, &c. by means of fire; or the act of changing them from their ſolid ſtate to a fluor.

The word is derived from the Latin *fuſio*; of *fundo*, *I pour out*. Whence, alſo, *effuſion*, *infuſion*, *ſuffuſion*, and *tranſfuſion*; which ſee.

To give the ore its metallic form, they *foſe* it: when it is in *fuſion*, the metalline ſubſtance being the heavieſt, ſinks to the bottom of the furnace; the other terreſtrial matters riſing, in form of ſcoria, to the ſurface.

It is commonly imagined, that the *fuſion* and metalline form of ores is wholly the effect of fire; and we have theories of fuſibility founded on this principle; but it is a miſtaken one. Fire, no doubt, is the principal agent; but fire, alone, is not ſufficient. A mineral, or piece of metal not purified, being put alone in a crucible, melts with great difficulty, and never becomes a perfect metal: copper ore, for inſtance, being thus applied, its impure part forms a ſcoria, and vitrifies; the metalline part reſiding at bottom, under the appearance of a black regulus.

To promote the *fuſion* and ſeparation, they mix coals, or ſtones, or cinders, or old ſcoriæ, along with the ore; the inflammable principle in which, by help of fire, fuſes them perfectly, ſets the heterogeneous part at liberty, and raiſes it to the top. See FLUX.

The general reaſon of *fuſion* is pretty eaſily aſſigned. The firmneſs or ſolidity of a body ariſes from the force wherewith its particles cohere. And the COHESION of all bodies is as the quantity of contact in the component particles.

Now, the corpuſcles of fire, entering with rapidity into the pores of the metal, agitate, and, by degrees, looſen, divide, and diminiſh their contact; till at length there is not enough to hinder their rolling over each other, and giving way upon the leaſt impulſe.

The dilatation obſervable in all *fuſion*, is a proof that the particles of the bodies are ſeparated, and ſet at a diſtance from each other; and, conſequently, their contacts and cohęſions diminiſhed.

In effect, rarefaction and dilatation are the neceſſary conſequences of fire and heat.

From the difference of cohęſion proceeds that variety we obſerve in the *fuſion* of bodies: for ſuch as have leaſt contact of parts, ſooneſt give way to the fire; and ſome will melt away by the warmth of a vapour only: thus air and mercury are ſo fuſible, that the heat of the atmoſphere is always ſufficient to keep them fluid; when others, which have a ſtronger contact, are not to be ſeparated without much difficulty. Upon this account, vegetables very eaſily diſunite, minerals ſlower, and metals ſloweſt of all; and of the laſt, thoſe wherein the contact of parts is leaſt, as in lead and tin, moſt readily melt; but thoſe which are moſt compact, as gold and ſilver, are not to be managed but by a violent heat.

If now the force of cohęſion were proportional to the quantity of matter, or to the weight of bodies, we might from ſtatics account for all the variety that occurs in *fuſion*: for by knowing the ſpecific gravity of a body, we ſhould then know what force is required to melt it; but becauſe the ſame quantity of matter may be ſo variouſly diſpoſed, that in one body there ſhall be a much greater contact than in another, though the gravity be equal or even greater in the latter, therefore the force of the cohęſion cannot be eſtimated by gravity; for lead though more ponderous than all other metals except gold, yet in the fire is more eaſily melted than almoſt any other; ſo that it neceſſarily follows, that in this metal there muſt be a leſs cohęſion, or contact of parts, how much ſoever it may exceed others in the quantity of its matter.

Bodies after *fuſion* return again into a ſolid maſs, upon removing them from the fire; becauſe their particles hereupon approach nearer to one another by their attractive force, and are compelled to unite.

Such as conſiſt of homogeneous and unalterable parts, as wax, gums, and the purer metals, recover their ancient form: for when the ſame texture of parts remains in the whole body, it muſt of courſe reaſſume the ſame appearance, when the ſeparating power ceaſeth to act; but other bodies, whoſe parts with reſpect to denſity and ſurface are extremely different from one another, while ſome are carried off by the force of heat, and others are changed as to figure and poſition, muſt be forced to appear in another form: for they cannot recover their original phaſes, unleſs every particle could reinſtate itſelf in that very ſituation it had before, which may be hindered infinite ways; as may be experienced eaſily in heterogeneous bodies.

The difference, therefore, obſerved even in homogeneous bodies after liquefaction, is no ways to be accounted for but from the changeableneſs of ſurface in their parts: for thoſe bodies whoſe parts conſtantly retain the ſame ſurfaces, never loſe their form; but others, by having the ſurfaces of their parts altered, have a different texture, and put on another appearance.

It had been formerly an opinion, very generally received that the ſolution of metals by lightning is effected by a kind of cold *fuſion*; and the inſtances that have been uſually alledged in ſupport of this opinion, are thoſe of a ſword being melted in its ſcabbard, and of money being melted in a bag, whilſt the ſcabbard and bag remained unhurt. But it appears, by a variety of experiments and obſervations, collected in the progreſs of ELECTRICITY to its preſent advanced ſtate, that this kind of *fuſion* is attended with heat and ignition, as in the caſe of common *fuſion*. Phil. Tranſ. vol. li. part i. art. 30 and 31.

FUST, in *Architecture*, the SHAFT of a column; or that part comprehended between the baſe and the capital; called alſo *the naked*.

The word is French, and literally ſignifies a *caſk*.

The *fuſt* is that cylindrical part, which makes, as it were, the body or trunk of the column, excluſive of the head and foot.

FUSTIAN, in *Commerce*, a kind of cotton ſtuff, which ſeems, as it were, quilted, or whaled on one ſide.

Menage derives the word from *fuſtanum*, which in the corrupt Latin writers is uſed in the ſame ſenſe, and is ſuppoſed to be formed from *fuſtis*, on account of the tree whereon the cotton grows. Bochart derives it from *fuſtat*, which, in Arabic, ſignifies the ancient city of Memphis, where cotton is produced in great abundance. Right *fuſtians* ſhould be made altogether of cotton thread both woof and warp.

There are *fuſtians* of divers kinds, wide, narrow, coarſe, fine, with ſhag or knap, and without it. There are alſo a great many made, whereof the warp is flax, or even hemp.

FUSTIAN, in *Criticiſm*, a word uſed to expreſs bombaſt.

FUSTICK, or FUSTOCK, a yellow wood uſed by the dyers.

The colour it yields is a fine golden yellow; but there ſhould be ſome other ingredients mixed with it, to make it laſting. The tree that yields it grows in all the Carribbee iſlands; particularly in Barbadoes and Tobago, where it riſes to a great height.

The dyers uſe it chiefly for BLACK; but ſome of the ableſt and honeſteſt among them, who would dye none but the beſt and moſt laſting colours, are of opinion it ſhould be abſolutely excluded out of all dying.

Beſide this, there is another kind of *foſtick* or *fuſtet*, growing in Italy, Provence, &c. which is uſed to dye a coffee-colour.

FUSTIGATION, in the *Roman Cuſtoms*, a puniſhment inflicted by beating with a cudgel. This puniſhment was peculiar to freemen; for the ſlaves were ſcourged or laſhed with whips.

FUSTIGATION, *fuſtigatio*, is alſo a penance enjoined by the Roman inquiſition.

FUSTUARIUM, in *Antiquity*, a Roman puniſhment, the ſame with FUSTIGATION.

FUSTUC, in *Botany*, a name given by ſome of the old writers to the tree which produces the piſtachia-nuts. The word ſounds ſo like the name of a wood uſed in dying, and called at this time *fuſtick*, that it might be ſuppoſed to expreſs ſome tree of the ſame kind; but it is of a very different origin. The Jews and Arabians have called the piſtachia-tree *fiſtic* and *fuſtack*, and from thence ſome have written the name *fuſtuck* or *fuſtuc*. the Greeks have written it φυστι, and the barbarous Latin writers *fiſticio*, which ſounds very like the name PISTACHIO.

FUT-FA, in *Muſic*. See F and CLEF.

FUTTOCKS, *in a Ship*, the timbers raiſed over the keel, or the compaſſing timbers which make her breadth. Thoſe next the keel are called *ground-futtocks*, and the reſt *upper futtocks*.

FUTTOCK *ſtrouds*. See SHROUDS.

FUTURE, ſomething to come hereafter.

We ſay a *future* ſtate, a *future* contingency; there is none but God to whom *future* things are preſent.

FUTURE, or FUTURE *Tenſe*, in *Grammar*, denotes an inflexion of verbs, whereby they denote, that a thing will be in ſome time yet to come. As, the laſt day will come: I ſhall ſee an end.

The *future* time admits of two caſes: either we may intend to expreſs a thing that ſhall come to paſs in a ſhort time; or a thing that ſhall happen in any indefinite time. Thus the Greeks have their *paulo poſt futurum*, μικρον υστερον μελλων, which marks a thing juſt going to be done as συστρεψω; beſide the common indefinite *future*, στρεψω, *I will do it*; *ſcribam*, *I ſhall write*.

In Latin, Italian, French, and even in Engliſh, the *future* of the indicative expreſſes only the deſign or intention of doing a thing, or ſimply that the thing will be; as, I will praiſe, I will be approved: and the *future* in the ſubjunctive ſhews, that the thing will be done under certain circumſtances; when I ſhall have ſeen Verſailles, I will tell you. Sometimes the *future* is expreſſed in Engliſh by the preſent; If I meet your friend, I will ſend him to you; *ſi offendero*, *ſi incidero*, &c.

Mr. Harris, in his diſtribution of tenſes, reckons three definite *future* tenſes, beſides the common indefinite *future*, which he calls the aoriſt of the *future*, viz. the inceptive *future*, as *ſcripturus ero*, *I ſhall be beginning to write*; the middle or extended *future*, as *ſcribens ero*, *I ſhall be writing*; and the completive *future*, as *ſcripſero*, *I ſhall have done writing*. See TENSE.

FUZE, or FUZEE. See FUSEE.

FUZEE, in the *Manege*, two dangerous ſplents, joining from above downwards: commonly a *fuzee* riſes to the knee and lames the horſe.

Fuzees differ from ſcrews or thorough ſplents in this, that the latter are placed on the two oppoſite ſides of the leg. See SPLENT.

FUZILEERS. See FUSILIERS.

G.

G, The ſeventh letter in our alphabet, and the fifth conſonant: though in the alphabets of all the oriental languages, the Hebrew, Phœnician, Chaldee, Syriac, Samaritan, Arabic, and even Greek, *G* is the third letter.

The Hebrews call it *ghimel*, or *gimel*, q. d. *camel*; becauſe it reſembles in its form the neck of that animal; and the ſame appellation it bears in the Samaritan, Phœnician, and Chaldee: in the Syriac it is called *gamel*, in Arabic *gim*, and in Greek *gamma*.

The letter *G* is of the mute kind, and cannot be any way ſounded without the help of a vowel. It is formed by the reflection of the air againſt the palate, made by the tongue, as the air paſſes out of the throat: which Martianus Capella expreſſes thus, *G ſpiritus cum palato*, ſo that the *G* is a palatal letter.

G in Engliſh has two ſounds, one from the Greek Γ, and the Latin, which is called that of the hard *G*, becauſe it is formed by a preſſure ſomewhat hard of the fore-part of the tongue againſt the upper gum; which ſound it retains before *a*, *o*, *u*, *l*, *r*; as *gate*, *go*, *gull*. At the end of a word it is always hard, as *ring*, *ſing*, &c. The other ſound, called that of the ſoft *G*, reſembles that of *j*, and is commonly, though not always, ſound before *e* and *i*, as in *gem* and *gibbet*. To this rule, however, there are many exceptions; *G* is often hard before *i*, as *give*, &c. and ſometimes before *e*, as *get*, &c. It is alſo hard in derivatives from words ending in *g*, as *ſinging*, *ſtronger*, &c. and generally before *er*, at the end of words, as *ſinger*. *G* is mute before *n*, as *gnaſh*, *ſign*. *Gh* has the ſound of the hard *G* in the beginning of a word, as *ghaſtly*; in the middle, and ſometimes at the end it is quite ſilent, as *right*, *though*. At the end of a word *Gh* has often the ſound of *f*, as *laugh*. Johnſon.

The Latins took the liberty to drop the letter *G* at the beginning of words, before an *n*; as in *gnatus*, *gnaſco*, *gnobilis*, *gnarrat*, &c. which they ordinarily wrote *natus*, *noſco*, *nobilis*, &c. They alſo frequently changed it into *c*; as *gamelus*, into *camelus*; *grogulus*, *graculus*; *quingentum*, *quimentum*, &c. Sometimes it was put inſtead of *n*, before a *c*, and for another *c*; as *Acchiſes*, *aggora*, *aggvilla*, &c. for *Anchiſes*, *ancora*, *anguilla*, &c. And inſtead of *p*; as *magalia*, for *mapalia*, &c. *G* is alſo uſed inſtead of *g*, and *g* inſtead of *G*, as in *anguino*, *anguina*, *anguina*, &c. inſtead of *r*, as in *aquarium*, for *aquarium*; *agger*, for *arger*, &c. And inſtead of *s*, as in *ſpargo*, *ſparſi*, *ſparſum*; or rather, it is retrenched from thoſe laſt words, to avoid the cacophony of *ſpargſi*, or *ſpargſi*. *G* is alſo put for *c*; as in *Gaius*, for *Caius*; *Caius*, for *Gaius*; *Gaeta*, for *Caieta*; and for *v*; as in *figere*, for *fivere*. See N, P, &c.

The northern people frequently change the *G* into *o*, or *w*; as in *Gallus*, *Wallus*: *Gallia*, *Wallia*, *Valia*, &c. For in this inſtance it muſt not be ſaid that the French have changed the *w* into *G*; becauſe they wrote *Gallus* long before *Wallus*, or *Wallia*, were known, as appears from all the ancient Roman and Greek writers.

And yet it is equally true, that the French change the *w* of the northern nations, and *w* conſonant, into *G*; as *Willelmus*, *William*, into *Guillaume*; *Wulphilas*, into *Gulphilas*; *Vaſco*, into *Gaſcon*, &c.

Diomed. lib. ii. cap. De Literis, calls *G* a new letter; his reaſon is, that the Romans had not introduced it before the firſt Punic war; as appears from the roſtral column, erected by C. Duilius, on which we every where find a *c* in lieu of *G*. It was Sp. Carvilius who firſt diſtinguiſhed between thoſe two letters, and invented the figure of the *G*; as we are aſſured by Terentius Scaurus. The *c* ſerved very well for *G*; it being the third letter of the Latin alphabet, as the *G* or γ was of the Greek.

The *G* is found inſtead of *c* on ſeveral medals: Vaillant, Num. Imperat. tom. i. p. 39. M. Beger produces a medal of the Familia Ogulnia, where GAR is read inſtead of CAR, which is on thoſe of M. Patin. But the *c* is more frequently ſeen on medals, in lieu of *G*; as AUCUSTALIS CALLAECIA CARTACINENSIS, &c. for AUGUSTALIS, &c. Not that the pronunciation of thoſe words are altered, but only that the *G* was unartfully or negligently cut by the workmen; as is the caſe in divers inſcriptions of the Eaſtern empire; where AUC, AUCC, AUCCC, were frequently found for AUG, &c.

The form of our *G* is taken from that of the Latins, who borrowed it from the Greeks; the Latin *G* being certainly a corruption of the Greek gamma, Γ, as might eaſily be ſhewn, had our printers all the characters and forms of this letter, which we meet with in the Greek and Latin MSS. through which the latter paſſed from Γ to *G*.

As to the gamma of the Greeks, it is manifeſtly the ג of the Hebrews or Samaritans. All the difference between the gamma and ghimel conſiſts in this, that the one is turned to the right, and the other to the left, according to the different manners of writing and reading, which obtained among thoſe different nations; ſo that all the pains Salmaſius has taken on Solinus, to prove that the *G* was derived from the Greek kappa, are loſt.

G, as a Roman abbreviature, has various ſignifications. It denotes *gratis*, *geni*, *gaudium*, &c. G. V. ſignifies *genio urbis*, and G. P. R. *gloria populi Romani*.

G has alſo been uſed as a numeral letter, ſignifying 400, according to the verſe,

G quadringentos demonſtrativa tenebit.

When a daſh was added at the top, $\overline{G}$, it ſignified forty thouſand.

G, in *Chronology*, is the ſeventh dominical letter.

G, on the French *Coins*, denotes the city of Poitiers.

G is alſo uſed, in *Muſic*, to ſignify one of the cleſs; viz. that of the higheſt part, called the *treble*, or *all*. See CLEFS, and TREBLE.

GABALE, in *Aſtrology*, a deity worſhipped at Heliopolis under the figure of a lion, with a radiant head; and it is thus repreſented on many medals of Caracallus.

GABARDINE, from the Italian *govardina*, has been ſometimes uſed to denote a coarſe frock, or mean dreſs. In this ſenſe it is uſed by Shakſpeare in his Tempeſt and Merchant of Venice, and by Butler in his Hudibras, book i.

GABBARA, a name which the Egyptians gave the dead bodies which they kept by them, inſtead of burying them.

That people, out of a cuſtom which they had received from their anceſtors, and which aroſe in ſome meaſure from the poſition of their country, which is expoſed to the inundations of the Nile, uſed to wrap up the bodies of perſons of eminence, particularly thoſe of ſaints and martyrs, in a great number of linen cloths, with balms and ſpices; and inſtead of interring them, they preſerved them in their houſes: thinking, that thereby they did them much more honour. See EMBALMING, and MUMMY.

And theſe, St. Auguſtine tells us, were what they called *gabbaras*. Sermon cxx *de diverſis*, cap. 12.

Pliny makes mention of the ſame thing, lib. vii. cap. 16. where he relates, that in the time of Claudius, a *gabbara* was brought from Arabia, almoſt ten feet long.

The word is Arabic, Syriac, and Hebrew, formed of גבר, *gaber*, a *man*, and denotes an embalmed body.

GABEL, or GABELLE, in the *French Cuſtoms*, a duty or impoſition on ſalt.

Etymologiſts are divided as to the origin of the word. Some

Some derive it from the Hebrew *gab*, a *present*; others from קבל, *to deliver*; others from קבלה, *kabbalah*, *receipt*; others from *ghabel*, or *gabe*, *unjust law*; and others from the corrupt Latin *gabella*, or *gabium*, *tribute*.

The *gabel* is let out to farm; and makes the second article in the king's revenue.

There are three farms of *gabels*: the first comprehends the greatest part of the kingdom; the second is that of the Lyonnois, and Languedoc; and the third that of Dauphiné and Provence. There are several provinces exempt from the *gabel*, having purchased that privilege of Henry II.

This duty is said to have had its rise in France, in 1286, under Philip the Fair. Philip the Long took a double per livre on salt, by an edict in 1318, which he promised to remit when he was delivered from his enemies; which was renewed by Philip de Valois, in 1345; and the duty was raised to four deniers per livre; king John resumed it in 1355, and it was granted to the dauphin in 1358, to ransom king John. It was continued by Charles V. in 1360; after his decease it was suppressed, but revived again by Charles VI. in 1381. Louis XI. raised it to twelve deniers per livre; and Francis I. in 1542, to twenty-four livres per muid; and it has been considerably augmented since that time; so that a minot of salt pays a duty of 42 livres, 8 sols, and 6den. Philip de Valois first established granaries and officers of the *gabelle*, and prohibited any other persons from selling salt; from which time the whole commerce of salt, for the inland consumption, has lain wholly in the king's hands, who sells and distributes every grain thereof by his farmers, and officers created for the purpose.

The produce of this impost is so considerable, that it is computed to make one fourth of the whole revenue of the kingdom.

GABEL, or GABLE, is also used, in some of our *Ancient Writers*, for any sort of tax, or imposition: as *gabel* of wines, of silk, &c.

GABINIA *toga*. See TOGA.

GABIONS, in *Fortification*, &c. are large cylindric baskets, open at both ends, made of osier twigs, about three feet high, and as much in diameter: having nine or ten stakes about an inch and a half in diameter, which exceeds the basket-work about five or six inches, and are pointed. These serve in sieges to carry on the approaches under cover, when they come pretty near the fortification. See *Tab.* VII. *Fortification*, *fig.* 39.

They are commonly used in BATTERIES, to screen the engineers, &c. in order to which one is placed on either side each gun, only leaving room for the muzzle to appear through.

There are also a smaller sort of *gabions*, about one foot high, twelve inches in diameter at the top, and from eight to ten at bottom, used on parapets, in trenches, &c. to cover the musqueteers; being placed so close as that a musquet can but just peep through.

They also serve as a parapet on lines, lodgments, &c. where the ground proves too hard to dig into.

GABIONS, *stuffed*, are five or six feet long, and as much in diameter, filled with branches and small wood, and serving to roll before the workmen in trenches, and to cover them in front against musket-shot. See MANTLET.

To render the *gabions* useless, they endeavour to set them on fire, by throwing pitched faggots among them.

GABIREA, in the *Materia Medica*, a name given by some of the old writers to such myrrh as was remarkably fatty.

GABLE, or GABLE-*end* of a house, is the upright triangular end; from the cornice, or eaves, to the top of its roof.

GABLE, *land*. See LAND-*gable*.

GABLOCKS, the artificial spurs of a *game*-COCK.

GABRES, or GAVRES, a religious sect in Persia and India; called also *Gebres*, *Geures*, &c. See MAGI.

The Turks call the Christians *Gabres*, q. d. infidels, or people of a false religion; or, rather, as Leunclavius observes, Heathens, or Gentiles: the word *Gabre*, among the Turks, having the same signification as Pagan, or Infidel, among the Christians; and denoting any thing not Mahometan.

In Persia, the word has a more peculiar signification wherein it is applied to a sect dispersed through the country, and said to be the remains of the ancient Persians, or followers of Zoroaster, being worshippers of fire. See FIRE, *everlasting*.

They entertain the most profound veneration for this ancient philosopher, whom they consider as the great prophet sent by God to communicate his law, and to instruct them in his will.

They have a suberb at Ispahan, which is called Gauraband, or the town of the Gauri, where they are employed in the meanest and vilest drudgery: some of them are dispersed through other parts of Persia; but they principally abound in Kerman, the most barren province in the whole country, where the Mahometans allow them liberty, and the exercise of their religion. Several of them fled many ages ago into India, and settled about Surat, where their posterity remain to this day. There is also a colony of them at Bombay. They are a poor, ignorant, inoffensive people, extremely superstitious and zealous for their rites, rigorous in their morals, and honest in their dealings. They profess to believe a resurrection and a future judgment, and to worship only one God. And though they perform their worship in the fire, and direct their devotion towards the rising sun, for which they have an extraordinary veneration, yet they strenuously maintain that they worship neither, but that these are the most expressive symbols of the Deity; and for this reason they turn towards them in their devotional services. See Thevenot's and Tavernier's Voyages, and Hyde's Rel. Vet. Pers. cap. xxiv.

However, some have supposed, that these are Persians converted to Christianity, who, being afterwards left to themselves, mingled their ancient superstitions with the truths and practices of Christianity, and so formed for themselves a religion apart: and they alledge that, throughout the whole of their system of doctrine and practice, we may discern the marks and traces of Christianity, though grievously defaced; the annunciation, the magi, the massacre of the infants, our Saviour's miracles, his persecutions, ascension, &c.

GABRIELITES, in *Ecclesiastical History*, a sect of Anabaptists, that appeared in Pomerania in 1530. They derive their name from Gabriel Scherling, who, after having been for some time tolerated in that country, was obliged to remove, and died in Poland.

GAD, in *Mining*, an instrument used to dig out the ore. It is a small punch of iron with a long handle of wood. One of the miners holds this in his hand, directing the point to a proper place, while the others striking it with a large sledge-hammer, drive it into the vein.

The working by this instrument is thence called *gadding*.

GAD-*fly*, in *Natural History*, a species of OESTRUS, with spotted wings, yellow breast and brown back, and yellow abdomen, terminating in a black point: the common name for a winged insect, called also the horse-fly or ox-fly, a creature very troublesome to cows, horses, &c. This creature, examined by the microscope, has several peculiarities worthy observation. It has, like the gnat, a long proboscis, with a sharp dart, and two darts sheathed within it; the use of which is to penetrate the hides of animals, and feed on their blood; whereas the proboscis serves to suck the juices, &c. from fruits, flowers, and leaves of plants.

The eggs of this fly are laid in the water, and these produce a remarkable maggot, of a brown colour and long flatted figure, with a pencil of fine downy hairs at the tail, which it spreads into a circular form at the surface of the water, whilst its head is plunged under it in search of food. In descending, these hairs are drawn together in an oval form, and made to enclose a bubble of air, by means of which the maggot is able to rise again; and if this bubble happens to escape, the creature squeezes another out of his body to supply its place. The snout of this maggot has three divisions, whence are thrust out three little pointed bodies, like serpents tongues. Those maggots are very common on the surface of ditch-waters, and the motion of their intestines is very singular and observable. Baker's Microsc. p. 202.

GADING, among *Miners*. See GAD.

GADUS, in *Ichthyology*, the name of a genus of the malacopterygious, or soft-finned fishes, in the Artedian system, the characters of which are these: the branchiostege membrane on each side contains seven bones of a somewhat cylindric form; the back in some species has three fins, and in others only two; the head in most species is compressed, but in some it is depressed.

Artedi enumerates the following distinctions, viz. those which have three fins and no cirri, of which there are three species, the whiting, the cole-fish, and the whiting-pollack: these which have three fins with cirri, to which belong the cod-fish, the haddock, the pouting, and the Cornish poor: those which have two fins in the back comprehend the hake, the ling, the eel-pout, and the bearded *gadus*, with a furrow at the first of the two back-fins, called in Cornwall the whistle-fish.

The *gadus*, in the Linnæan system, is a genus of the JUGULARES: it has a smooth head, seven slender branchiostegous rays, an oblong body with deciduous scales; all the fins are covered with a common skin, and the ventral fins are slender, and terminate in a point.

GADWALL, *anas strepera*. See DUCK.

GÆLÆUM, *earth of*, in *Natural History*, a name given by

by ſome of the old writers to the PETROLEUM, or, as we uſually call it, oil of petre.

GAFET, in the *Materia Medica of the Arabians*, a name given by Avicenna and others to the farcocolla of the Greeks.

GAFF, in *Sea-Language*, a ſort of boom or pole uſed to extend the upper edge of the mizen; the foremoſt or inner extremity of it is furniſhed with two cheeks, forming a ſemi-circle, which incloſe the after-part of the maſt, ſo as to confine the *gaff* cloſe to its reſpective maſt whilſt the ſail is hoiſting or lowering.

GAFFS. See GARLOCKS.

GAFOLD-*land*, or GAVEL-*land*, *terra ſenſualis*, in *our old Writers*, land liable to taxes, and rented or let for rent.

GAGATES. See JET.

GAGATRONICA, a word uſed by the *Writers of the Middle Age*, as the name of a diſtinct ſtone, but ſeeming only a falſe ſpelling of the word GAGATRONIUM.

GAGE, in our *ancient Cuſtoms*, ſignifies a pledge, or pawn, given by way of ſecurity.

The word is only properly uſed in ſpeaking of moveables: for immoveables, the term *hypotheca* is uſed.

If the *gage* periſh, the perſon who received it is not to anſwer for it, but only for extreme negligence, &c.

GAGE is alſo uſed for a challenge to COMBAT.

In which ſenſe it was a pledge, which the accuſer, or challenger, caſt on the ground, and the other took up, as accepting the challenge: this was uſually a glove, gantlet, chaperoon, or the like.

The Grand Cuſtomary mentions *gages pleiges de duel*.

Theſe were gentlemen of the relations or friends of the combatants. If he who had given the *gages pleiges* was overcome, he was to pay a mulct agreed on.

GAGE is only now retained as a ſubſtantive: as a verb, the *g* is changed into *w*; and of *gage* is formed *wage*. As, to *wage* law, to *wage* deliverance, q. d. to give ſecurity a thing ſhall be delivered.

If a perſon who has diſtrained be ſued for not having delivered what he had took by diſtreſs, he ſhould *wage*, or *gage*, or *pogir*, deliverance; that is, put in ſurety that he will deliver them.

GAGE, *mort*, *mortuum vadium*, is that which is left in the hands of the proprietor, ſo that he reaps the fruits thereof; in oppoſition to *vif-gage*, *vivum vadium*, where the fruits or revenues are reaped by the creditor, and reckoned on the foot of the debt, which diminiſhes in proportion thereto. The ſecond acquits or diſcharges itſelf, and as it ſubſiſts, ſurvives the debt, and is therefore called living pledge; the firſt does not.

Pomey alſo uſes MORT-GAGE for the poſſeſſion of any effects, on condition of ſurrendering them up at the good pleaſure of the perſon who gave them.

GAGE, in the *Sea Language*. When one ſhip is to windward of another, ſhe is ſaid to have the *weather-gage* of her.

The ſeamen, alſo, call trying how much water a ſhip draws, *gaging*, or rather *guaging* of her; and it is done thus:

They drive a nail into a pike, near the end, and then put down this pike by the rudder, till the nail catch hold under it; for then, as many feet as the pike is under water is the ſhip's *gage*, or depth of water ſhe draws.

GAGE, in *Joinery*, is an inſtrument made to ſtrike a line truly parallel to the ſtraight ſide of any board, or piece of ſtuff.

Its chief uſe is for *roging* of tenons true, to fit into mortiſes: and for *guging* ſtuff of an equal thickneſs.

It is made of an oval piece of wood, fitted upon a ſquare ſtick, to ſlide up and down ſtiffly thereon, and with a tooth at the end of a ſtaff, to ſcore, to ſtrike a line upon the ſtaff at any diſtance, according to the diſtance of the oval from it.

GAGE, among *Letter-founders*, is a piece of box, or other hard wood, variouſly notched; which is uſed to adjuſt the dimenſions, ſlopes, &c. of the different ſorts of letters. There are ſeveral kinds of theſe *gages*. See FOUNDERY.

GAGE, in *Pneumatics*, is of various ſorts, according to the purpoſes to which it is applied. Thus,

GAGE *of the air-pump*. See AIR-*pump*. The extraordinary powers of exhauſtion in Mr. Smeaton's air-pump, as they are indicated by his pear-*gage*, have lately been conſidered with peculiar attention by Mr. Nairne, F. R. S. He was led to proſecute a ſeries of experiments on this ſubject, by obſerving the remarkable difference between the indications of exhauſtion and rarefaction by this *gage*, and by the common barometer-*gage*. Having uſed every poſſible precaution in preparing his different *gages*, he nevertheleſs found, that, when they were put under a receiver, placed on a leather dreſſed in alum, and ſoaked in oil and tallow, according to his uſual method, and the pump was worked for ten minutes, the quickſilver in the barometer-*gage* roſe to within one tenth of an inch of the height of the quickſilver in the ſtandard barometer, which was at that time of thirty inches, and indicated that the air had been rarefied only about three hundred times; whereas Mr. Smeaton's pear-*gage* indicated a degree of exhauſtion equal to ſix thouſand times, the whole of its cavity, on dipping its open end into the cup of quickſilver and letting in the air, except a ſix thouſandth part, being filled by the quickſilver. The difference of indications by theſe two *gages* was found much more conſiderable in ſubſequent experiments. Having an opportunity of repeating ſome of theſe experiments before the honourable Henry Cavendiſh, Mr. Smeaton, and others, in April 1776, Mr. Cavendiſh accounted for the obſerved and aſtoniſhing difference, by referring to ſome experiments of his father, lord Charles Cavendiſh, from which it appeared, that water, wherever the preſſure of the atmoſphere on it is diminiſhed to a certain degree, is immediately turned into vapour, and reduced as ſuddenly to water again on reſtoring the preſſure: the degree of preſſure varies according to the temperature of the water; for when the heat is 72° of Fahrenheit's ſcale, it turns into vapour as ſoon as the preſſure is reduced to that of three quarters of an inch of quickſilver, or about one fortieth of the uſual preſſure of the atmoſphere; but when the heat is only 42°, the preſſure muſt be reduced to that of a quarter of an inch of quickſilver, or to one hundred and twentieth of the uſual preſſure, before the water turns into vapour. According to this theory, wherever the air in the receiver is exhauſted to the above mentioned degree, the moiſture adhering to the different parts of the machine, will be converted into an elaſtic vapour, and ſupply the place of the air, which is drawn away by the working of the pump; and the fluid left in the receiver and pear-*gage* will be chiefly this vapour. When the air is let into the receiver, the vapour within the pear-*gage* will be reduced to water, and only the real air will remain uncondenſed: and therefore this *gage* only ſhews how much real air is left in the receiver, and not how much the preſſure or ſpring of the included air is diminiſhed; whereas the barometer-*gage* ſhews how much the included fluid is diminiſhed, and that equally, whether it conſiſts of air or vapour. In order to aſcertain the truth of this plauſible theory, Mr. Nairne proceeded to free every part of his apparatus as much as poſſible from any adhering moiſture, concluding that by this means he ſhould be able to bring the two *gages* to an agreement. Inſtead of placing the receiver on leather, as before, he put it on the pump-plate, made as clean and dry as poſſible, and applied a cement round its edge to exclude the outward air. When the pump in this ſtate was worked for ten minutes, the barometer-*gage* indicated a degree of exhauſtion nearly equal to ſix hundred; and, on letting the air into the receiver, the pear-*gage* indicated a degree of exhauſtion little more than ſix hundred alſo. In another experiment he put a piece of the oiled leather above mentioned in the receiver, and found, on working the pump, that the barometer-*gage* indicated a degree of exhauſtion of nearly three hundred, but the pear-*gage* indicated a degree of exhauſtion not leſs than four thouſand. But on taking out the piece of leather, and repeating the experiment, the two *gages* agreed, as before. Having thus concluded, in general, that a conſiderable quantity of vapour ariſe from the compound of leather, alum, oil, and tallow, it was his next object to find out from which of theſe ſubſtances the vapour was principally derived. For this purpoſe he ſeparately and ſucceſſively included in the receiver two ounces of tallow, the ſame quantity of oil and of alum, and a piece of leather as it comes from the leather-ſellers, weighing a hundred grains: from theſe experiments he found that the elaſtic vapour, which occaſioned ſo great a difference in the teſtimony of the *gages*, ariſe chiefly from the leather, and very little from the tallow, oil, and alum. In the experiment with the leather, it ſupplied the place of the exhauſted air to ſuch, that he could not in ten minutes make the barometer-*gage* indicate a degree of exhauſtion of more than a hundred and fifty-nine; whereas that of the pear-*gage* was a hundred thouſand. In order to determine whether the difference in the *gages* was occaſioned by the moiſture of the leather, Mr. Nairne repeated the experiment with a piece of freſh leather, weighing a hundred grains. The pear-*gage* indicated a rarefaction of a hundred thouſand, and the leather had loſt two grains of its weight; when the ſame piece of leather was ſo thoroughly dried by the fire till it would loſe no more of its weight, and thus reduced to eighty grains, it gained two grains in the experiment, and the pear-*gage* exhibited a rarefaction only of two hundred and eighty. The leather was afterwards held in the

ſtream of hot water till it had regained its former moiſture and weight, and the degree of exhauſtion indicated by the pear-*gage* was a hundred thouſand, and the loſs of weight two grains, as before. In the firſt of theſe experiments, the degree of rarefaction indicated by the barometer-*gage* was a hundred and thirty-four; in the ſecond, two hundred and ſixty-eight; and in the third, one hundred and forty-ſeven. The effect of the vapour ariſing from ſmall quantities of different fluids, and from other ſubſtances containing moiſture, was tried in a variety of inſtances; and having found that the ſmall quantity of moiſture which exhaled from the ſubſtances under the receiver, prevented the pump from exhauſting to a conſiderable degree, Mr. Nairne ſuſpected that whenever wet leather had been uſed to connect the receiver with the plate, there muſt have ariſen ſo great a quantity of vapour as to have prevented the degree of exhauſtion from being near ſo great as in other inſtances. This led him to another ſet of experiments, in order to aſcertain this fact. Having firſt placed the receiver on the pump-plate, made clean and dry, with only a little oil poured round the outſide edge of it, both *gages* agreed in indicating a rarefaction of ſix hundred, as before: but when the receiver was ſet on leather, that had been ſoaked for two days in water, the rarefaction indicated by the barometer-*gage* was uniformly fifty-one in three different trials; but the pear-*gage* exhibited firſt ſixteen thouſand, in the ſecond inſtance fifteen hundred, and in the third one thouſand: when the receiver was placed on a piece of leather, ſoaked in a mixture of water and ſpirit of wine, the barometer-*gage* in three trials always indicated a degree of exhauſtion equal to forty-ſeven; but the pear-*gage* was unaccountably various; in the firſt trial being twelve thouſand; in the ſecond, eleven hundred and fifty; and in the third, five hundred. By theſe experiments it ſufficiently appears, that the uſe of leather ſoaked in water, or in water and ſpirit of wine, prevents the pump from exhauſting to any conſiderable degree. By two other experiments, in which water was uſed for ſoftening the leathers of the piſtons of a common air-pump, we find that the higheſt degree of rarefaction that could be procured was thirty-ſeven, according to the barometer-*gage*, and thirty-eight, according to the pear-*gage*. Mr. Nairne's laſt experiment furniſhes a very extraordinary evidence of the effect of vapour on the barometer-*gage*: having put a phial of ether under the receiver, in order to produce artificial cold, and working the pump for half an hour, the degree of exhauſtion indicated by the barometer-*gage* was only fifteen; though the ſame pump exhauſted above four hundred times before the ether was put under the receiver. The degree of cold produced by means of ether, in the exhauſted receiver, was 48°, below 0 in Fahrenheit's ſcale, or 103° below 55°, which was the temperature of the air in the room where the experiment was made. Phil. Tranſact. vol. lxvii. part ii. art. 32. page 614, &c.

GAGE *of the barometer*, is a contrivance for eſtimating the exact degree of the riſe and fall of the mercury in the Torricellian tube. It is well known, that whilſt the mercury riſes in the tube, it ſinks in the ciſtern, and *vice verſâ*; and, as the diſtance between the diviſions graduated on the annexed ſcale and the ſurface of the mercury in the ciſtern is not truly ſhewn by the numbers on the ſcale, errors muſt happen in determining the preciſe height of the mercury. To remedy this inconvenience, a line is cut upon a round piece of ivory, which is fixed near the ciſtern: this line is accurately placed at a given diſtance from the ſcale; e. gr. twenty-ſeven inches; and a ſmall float of cork, with a cylindric piece of ivory fixed to its upper ſurface, on which a line muſt be cut at the diſtance of two inches, exactly from the under ſurface of the cork, is left to play freely on the quickſilver, and the cylinder works in a groove made in the other piece: from this conſtruction it appears, that if theſe marks are made to coincide, by raiſing or lowering the ſcrew which acts on the quickſilver, then the diviſions on the ſcale will expreſs the true meaſure of the diſtance from the ſurface.

GAGE *of the condenſer*, is a glaſs tube of a particular conſtruction, adapted to the condenſing engine, and deſigned to ſhew the exact denſity and quantity of the air contained at any time in the CONDENSER. For this purpoſe, let *Dabcf*, *Tab.* II. *Pneumatics*, *fig.* 22. be a ſmall glaſs tube, about one tenth of an inch in diameter, open at D, but hermetically ſealed at *f*; D*a*, a larger tube, hermetically ſealed at D, and containing at that end a quantity of mercury, which takes up two or three inches in length, and covers the open end of the ſmaller tube: the other end C, of the large tube, is ſtrongly cemented into the braſs elbow-piece O*E*e at C, *fig.* 23. ſo as not to be quite at right angles with O*e*, but to incline a little downwards, that the mercury at D may not run towards C, and paſs into the condenſing glaſs G B. This *gage* is ſcrewed on at *e*, and the injecting ſyringe at O, a cock being interpoſed at O or *e*, or not uſed at all, according to the nature of the experiment. Whilſt air is injected into the condenſing glaſs, and the large tube of the *gage* at the ſame time, the air in the ſmaller tube, which has no communication with the injected air, muſt be rarer and weaker; and, therefore, the mercury at D will enter the tube, and advance in it, in proportion to the condenſation of the air in GB. In *fig.* 22. *d*, *f*, *f*, repreſent three rings of ſpringy wire, at ſuch diſtances as to ſhew, by the motion of the mercury in the ſmall tube, when the denſity of the air is doubled, tripled, or quadrupled; becauſe the air, which at firſt filled the whole ſmall tube, now takes up only the ſpaces *cd*, *ce*, *cf*; or in Mr. Haukbee's ſtyle, one, two, or three atmoſpheres are thrown in.

Another kind of *gage* may be put within the condenſing glaſs, at the bottom of it, when the uſe of the preceding *gage* would be inconvenient. This is a ſhort cylinder of wood, *fig.* 24. about an inch thick, with a hole through its middle between *a* and *b*, of about ⅓ inch in diameter; the outward diameter of the cylinder muſt be about four inches, ſo that the cylinder may eaſily ſtand within the condenſing glaſs on the plate, ſupporting its bottom at B, *fig.* 23. There is a hole at A of about ⅛ of an inch in diameter, and ⅜ of an inch deep, filled with mercury; *a c d b* is a ſmall glaſs tube, open at *a*, but hermetically ſealed at *b*, and bent to a right angle at *c*, the middle of the diſtance between *a* and *b*. When the open end *a* is immerſed in mercury, and the air on the ſurface of the mercury condenſed, the air in the tube will recede towards the elbow *c*, and the mercury, following it, ſhew to what degree it is condenſed. When the mercury is at *c*, then one additional atmoſphere bears upon its ſurface, and two atmoſpheres, if it be come to *d*; which places are marked by rings of ſpringing braſs wire; at *a* and *b*, about an inch of the ends of the tube are bent to a right angle, that the end *b* may go into the wood, whilſt the end *a* goes under the ſurface of the mercury, where it is held by a cork, whilſt air is injected into the condenſing glaſs. Deſaguliers, Exp. Phil. vol. ii. p. 394, &c.

GAGE, *ſea*. See ALTITUDE.

GAGE, *bucket ſea*, an inſtrument contrived by Dr. Hales, to find the different degrees of coolneſs and ſaltneſs of the ſea, at different depths: it conſiſts of a common houſhold pail or bucket, with two heads. Theſe heads have each a round hole in the middle, about four inches in diameter, covered with ſquare valves opening upward; and that they may both open and ſhut together, there is a ſmall iron rod, fixed to the upper part of the lower valve, and the other end to the lower ſide of the upper valve. So that as the bucket deſcends with its ſinking weight into the ſea, both the valves may open by the force of the water, which by that means has a free paſſage through the bucket. But when the bucket is drawn up, then both the valves ſhut by the force of the water at the upper part of the bucket; ſo that the bucket is drawn up full of the loweſt ſea water to which it has deſcended.

When the bucket is drawn up, the mercurial thermometer fixed in it is examined; but great care muſt be taken to obſerve the degree at which the mercury ſtands, before the lower part of the thermometer is taken out of the water in the bucket, leſt it be affected by the different temperature of the air.

In order to keep the bucket in a right poſition, there are four cords fixed to it, reaching about three feet below it; to which the ſinking weight is fixed.

The reſult of ſeveral trials with this *gage* was, that, when it was let down to different depths, from 360 feet to 5340 feet, in lat. 25° 13′ N. and long. 25° 12′ W. it was diſcovered by the thermometer, that the cold increaſed gradually in proportion to the depths, till it deſcended to 3960 feet, viz. near ¾ of a mile, whence the mercury in the thermometer came up at 53°: and though it was afterwards ſunk to 5346 feet, i. e. a mile and 60 feet, it came up no lower: the warmth of the water upon the ſurface, and that of the air, was all that time 84°.

When the water in the bucket was become of the ſame temperature with that on the ſurface of the ſea, equal quantities of both were weighed and tried by the hydrometer: that from below was found to be the heavieſt, and, conſequently, the ſalteſt. See Treatiſe on Ventilators, part ii. p. 122, &c.

Dr. Hales was probably led to the conſtruction of this ſea-*gage* from an inſtrument invented by Dr. Hook, and deſigned for the ſame purpoſe. This conſiſts of a ſquare wooden bucket C, *Tab. Miſcellany*, *fig.* 16. whoſe bottoms are ſo contrived, that, as the weight A ſinks the

iron

Iron B, to which the bucket C is faſtened by two handles D, D, on the end of which are the moveable bottoms or valves E E, and thereby draws down the bucket, the reſiſtance of the water keeps up the bucket in the poſture C, whereby the water, whilſt the bucket is deſcending, hath free paſſage through it; whereas, as ſoon as the bucket is pulled upwards by the line F, the reſiſtance of the water to that motion beats the bucket downwards, and keeps it in the poſture G, whereby the included water is kept from getting out, and the ambient water kept from getting in. Phil. Tranſ. N° 9. p. 149. and N° 24. p. 447. or abr. vol. ii. p. 280.

GAGE, *aqua-mercurial*, is the name of an apparatus contrived by Dr. Hales, and applied, in various forms, to the branches of trees, in order to determine the force with which they imbibe moiſture. See *Veg. Staticks*, *Explanation of the Inſtruments*, *fig.* 27. be a cylindric glaſs, c. gr. of an inch diameter within, and eight inches long. Into this glaſs is introduced the branch of a young thriving apple tree *b*, about three feet long, with lateral branches; the diameter of the tranſverſe cut *t* being ½ of an inch. Having fitted the joint *r* to the tube at *r*, by folding a piece of theep's ſkin round the them, it is cemented with a mixture of bees-wax and turpentine melted together in ſuch a proportion, as to make a very ſtiff clammy paſte when cold, and over the cement folds of wet bladders are bound firmly with packthread. To the lower end *s* of the large tube, a ſmaller tube *s t* is cemented, being about ½ of an inch diameter, and eighteen inches long, and in ſubſtance full ½ of an inch thick. Theſe tubes are cemented together at *s* with common hard brick-duſt or powdered chalk cement, and the joint is farther ſecured with the cement of bees-wax and turpentine, over which a wet bladder is bound. The apparatus being thus prepared, the branch is turned downwards, and the glaſs tube upwards, and then both tubes are filled with water; with the finger applied to the open end of the ſmall tube, it is inverted and immerſed in the glaſs ciſtern *n*, full of mercury and water. In this ſituation the lower end of the branch was immerſed ſix inches in water, via from *r* to *t*; the water was imbibed by the branch at its tranſverſe cut *t*; and during its aſcent into the ſap-veſſels of the branch, the mercury roſe in the tube *r s* from the ciſtern *n*, ſo that in half an hour it was riſen 5½ inches high, as far as *z*. The height of the mercury indicated, in ſome meaſure, the force with which the ſap was imbibed, though not the whole force; becauſe, while the water was imbibed by the branch, its tranſverſe cut was covered with innumerable little hemiſpheres of air, and many air-bubbles iſſued out of the ſap veſſels, which partly filled the tube *r s*, as the water was drawn out of it: and, therefore, the height of the mercury could only be proportionable to the excels of the quantity of water drawn off above the quantity of the air, which iſſued out of the wood. If the quantity of air, iſſuing from the wood, had been equal to the quantity of water imbibed, it is plain that the mercury could not riſe at all, becauſe there would be no room for it in the tube: but, if nine parts in twelve of the water be imbibed by the branch, and only three ſuch parts of air iſſue into the tube in the ſame time, the mercury muſt riſe near ſix inches, and ſo proportionably in other caſes. Dr. Hales obſerved, that the mercury roſe higheſt, in moſt caſes, when the ſun was clear and warm, and that it ſubſided three or four inches towards evening, but roſe again the next day as it grew warm, though ſeldom ſo high as at firſt. Dr. Hales adapted the ſize and ſhape of the glaſs apparatus to a great variety of branches of ſeveral trees and of different kinds of trees, and repeated the experiment above deſcribed, *materia vaticinii*, in a variety of inſtances. See his Vegetable Statics, vol. i. chap. ii. p. 84. &c.

GAGE, *ſailing*, is a tool uſed by mathematical inſtrument makers, for meaſuring and ſetting off diſtances: it conſiſts of a beam, tooth, ſliding ſocket, and the ſhoulder of the ſocket.

GAGE, *tide*, is the name of an inſtrument uſed for determining the height of the tides by Mr. Bayly, in the courſe of a voyage towards the ſouth-pole, &c. in the Reſolution and Adventure, in 1772, 1773, 1774, and 1775.

This inſtrument conſiſts of a glaſs tube, whoſe internal diameter was ſeven tenths of an inch, lathed faſt to a ten feet fir rod, divided into feet, inches, and quarters; this rod was faſtened to a ſtrong poſt fixed upright and firm in the water. At the lower end of the tube was an excerning ſmall aperture, through which the water was admitted. In conſequence of this conſtruction, the ſurface of the water in the tube was ſo little affected by the agitation of the ſea, that its height was not altered one tenth of an inch, when the ſwell of the ſea was two feet; and Mr. Bayly was certain, that with this inſtrument he could diſcern a difference of one tenth of an inch in the height of the tide.

GAGE, *water*. See ALTITUDE and HYDROMETER.

GAGE, *weather*, in *Sea-language*. See GAGE, above.

GAGER *de ley*. See WAGER *of law*.

GAGER, and } in *Geometry*. See } GAUGER.
GAGING, } GAUGING.

GAGNOLA, in *Ichthyology*, a name given by the Spaniards to a ſpecies of the acus, or ſyngnathus of Artedi. The particular ſpecies meant by it, is that called by Artedi, the hexagonal bodied ſyngnathus with the pinnated tail; others call it the acus Ariſtotelis, or acus ſerpentis, and the French the trompette: we call it ſometimes the needle-fiſh, ſometimes the trumpet-fiſh, and ſometimes the tobacco-pipe-fiſh.

GAHALA, in *Botany*, a name given by ſome writers to the *colocaſia*, or great Egyptian ARUM.

GAIANITES, GAIANITÆ, a ſect of ancient hereticks, ſprung from the EUTYCHIANS.

This ſect was of an older ſtanding than Gaian, a biſhop of Alexandria in the ſixth century, from whom, however, they took their name. They adhered to the opinion of Julian Halicarnaſſeus, the chief of the Incorruptibles and Phantaſtici; and came, at length, to be denominated *Gaianites*, upon *Gaian's* putting himſelf at their head. They denied that Jeſus Chriſt, after the hypoſtatical union, was ſubject to any of the infirmities of human nature.

GAIDEROPSARUS, in *Ichthyology*, a name given by ſome to a fiſh of the trutteraceous kind caught in the Mediterranean, and more uſually called CALLARIAS.

GAIN, the profit, or lucre, a perſon reaps from his trade employment, or induſtry.

Some derive the word from the German *gewin*; whereof the Italians had made *guadagno*; the French and Engliſh, *gain*.

There are legal and reputable *gains*, as well as ſordid and infamous ones. What is *gained* beyond a certain ſum, by gaming, is all liable to be reſtored again, if the loſer will take the benefit of the law.

GAIN, in *Architecture*, is the workmen's term for the bevelling ſhoulder of a joiſt, or other timber.

It is uſed, alſo for the lapping of the end, of the joiſt, &c. upon a trimmer, or girder; and then the thickneſs of the ſhoulder is cut into the trimmer, alſo, bevelling upwards, that it may joiſt receive the *gain*; and ſo the joiſt and trimmer lie even and level with the ſurface. This way of working is uſed in floors and hearths.

To GAIN *the wind*, in *Sea Language*, is to arrive on the weather-ſide, or to windward of ſome other veſſel in ſight, which both are plying to windward, or ſailing as near the wind as poſſible.

GAINAGE, GAINAGIUM, in our *Ancient Writers*, ſignifies the draught-oxen, horſes, wain, plough, and furniture, for carrying on the work of tillage by the baſer ſort of tenemen and villains.

Gainage is the ſame with what is otherwiſe called *wainage*. Bracton, lib. i. cap. 9. ſpeaking of feods and tenements, ſays, *Et ſi res deficiunt, quod ſæpius non geſtit ſic* per wainagium *juxta*. And again, lib. iii. tract. 2. cap. 1. *Villanus non amerciabitur, niſi ſalvo* wainagio *ſuo*. For anciently, as it appears both by Mag. Chart. and other books, the villain, when amerced, had his *gainage*, or *tounage*, free; to the end his plough might not ſtand ſtill: and the law, for the ſame reaſon, does ſtill allow a like priviledge to the huſbandman; that is, his draught-horſes are not, in many caſes, diſtrainable.

GAINAGE is alſo uſed for the land itſelf, or the profit raiſed by cultivating it.

GAIOPHRAGNIA, in *Natural Hiſtory*, a genus of the firſt order of ALKALIES, divided by partitions of earthy matter.

GALACHIDES, or GARATIDES, in *Natural Hiſtory*, the name of a ſtone to which the writers of the middle ages have attributed many ridiculous virtues. They have left us no further deſcription of it, than that it was of a blackiſh colour.

GALACTITES, in *Natural Hiſtory*, a ſtone, thus called, becauſe when broken, or ground with water, it yields a white liquor, like milk, which the Greeks call γαλα.

This ſubſtance much reſembles the morochthus, or French chalk, in many reſpects, but differs from it in colour. The ancients found it in the Nile, and ſome other rivers in Greece, and uſed it in medicine as an aſtringent, and for deſtructions and ulcers of the eyes. It has been ſuppoſed to increaſe the milk of nurſes, and hung on the necks of children to promote dentition. At preſent it is common in Germany, Italy, and ſome parts of France, and is wholly overlooked, being eſteemed only a woſſe kind of the MOROCHTHUS.

It is a very hard and dry ſubſtance, an indurated clay, of a cloſe compact texture, very heavy, and in colour of a pale

a pale grey, without the leaſt admixture of any other tinge. It is of a leſs even ſurface than the monochithus, and is leſs lard. It melts but ſlowly in the mouth, and leaves ſomething of a luſcious ſweetneſs on the tongue. It does not adhere to the lips or tongue, and if rubbed down on a marble with water, it diſſolves into a ſubſtance of a pure white, reſembling milk. It does not ferment with acids, and in burning becomes of a pure white. Hill's Hiſt. of Foſſ. p. 23.

GALACTOIDES, Γαλακτοειδὲς, of γαλα, *milk*, and εἰδος *form*, *milky*, a word uſed by the ancients in two or three different ſenſes. Some uſed it to expreſs tepid, or a little warm, with ſuch a heat as that of milk juſt drawn from the cow; others expreſſed by it a white, ſomewhat opake, or milky-colour; others expreſſed by it only a want of tranſparence in fluids. Galen frequently uſes it in the ſecond of theſe ſenſes, when treating of urines.

GALACTOPHAGI, and GALACTOPOTÆ, in *Antiquity*, perſons who lived wholly on milk, without corn, or the uſe of any other food.

The words are compounded of γαλα, γαλακτος, *milk*; φαγειν, *to eat*; and ποτης of ποτος, *I drink*.

Certain nations in Scythia *Aſiatica*, as the Getæ, Nomades, &c. are famous, in ancient hiſtory, in quality *of galactophagi*, milk-eaters. Homer makes their eloge, Iliad, lib. iii.

Ptolemy, in his Geography, places the *galactophagi* between the Riphæan mountains on one ſide, and the Hircanian Sea on the other.

GALACTOPHOROUS *Auct.*, are ſuch veſſels as ſerve to convey milk.

GALACTOPOTÆ. See GALACTOPHAGI.

GALACTOPSIA, a method of curing diſeaſes by drinking milk only. The gout, conſumption, and many other chronical diſeaſes, are by many affirmed to be curable by this means. See Cheyne's Nat. Meth. of curing Diſeaſes.

GALACTOSPONDA, Γαλακτοσπονδὰ, of γαλα, *milk*, and σπονδὴ, *libation*, in *Antiquity*, a LIBATION made with milk.

GALACTOSIS, of γαλακτοω, *to be converted into milk*, the production of milk; or the action whereby the food, or chyle, is converted into milk.

GALADES, in *Natural Hiſtory*, an epithet given by Rondeletius to a ſpecies of CHAMA, remarkable for its milky whiteneſs. It is derived from the Greek γαλα, *milk*. This CHAMA is a very elegant ſhell.

GALANGAL, GALANGA, a medicinal root, brought from the Eaſt Indies; the produce of a plant of the ſame name.

Its characters are theſe. It hath a ſingle ſpatha of one leaf; the flower has one petal with a tender tube, divided in ſix parts, three of them alternately oval and ſpear-ſhaped, the other oval, and at bottom cut into two parts, which are vertically heart-ſhaped; and it hath one ſtamen which is membranaceous; it has a round pennet, ſupporting a ſtyle the length of the tube; which afterwards become a roundiſh three-cornered capſule with three cells filled with ſeeds. We have but one ſpecies of this plant in England, known by botanical writers under the title of *Kæmpferia*, and is a genus of the *monandria monogynia* claſs.

There are two kinds of *galangals*, the *ſmall* and the *great*. The *ſmaller* is by far the moſt in eſteem, and is almoſt the only one heard of in preſcription. The *galanga minor*, or leſſer *galangal*, is a ſmall ſhort root, of an irregular figure, of the thickneſs of a man's little finger and is ſeldom met with in pieces of more than an inch or two long. It has ſeveral protuberances at its ends, and on its ſurface, and is ſurrounded with many circular rings, that ſtand out a little beyond the reſt of the ſurface. It is of an extremely firm and compact texture, yet not heavy; it cuts difficultly with a knife, and leaves a poliſhed ſurface. Its colour is a browniſh-red on the outſide, and ſomewhat brighter-red within, though ſtill with a conſiderable admixture of brown.

The ſmall *galangals* are to be choſen full and plump, and of a bright colour, very firm and ſound, and of an acrid and inſupportable hot taſte.

They were formerly in common uſe as warm ſtomachic bitters, and generally made an ingredient in bitter infuſions; but they are now almoſt wholly laid aſide, on account of their unpleaſant flavour. Bitterneſs does not appear to be the proper medical character of this root; the heat and pungency greatly prevailing. A very fiery extract is made from it with rectified ſpirit, and the watery extract is alſo very hot and pungent: in diſtillation with water, it yields an eſſential oil, about a ſcruple in quantity from ſixteen ounces, of little ſmell, and no great pugency: ſo that the pungent matter of the *galangal* appears to be of the ſame nature with that of pepper reſiding not in the volatile oil, but in a more fixed matter. Lewis, Mat. Med.

The larger *galangal* grows chiefly in Java and Malabar, and anſwers pretty much to the above deſcription, only that it is larger in bulk, leſs unequal and tuberous, weaker, and more diſagreeable than the leſſer kind.

The *galangals* are both brought us from the Eaſt Indies, and are the roots of the ſame plant, which is of the number of the *herbæ bulboſæ offines* of Mr. Ray. Herman calls that which produces the larger, *bunchale Indorum*; and that which produces the leſſer, *laguchi Indorum*.

The people of the Eaſt Indies uſe theſe roots by way of ſpice.

GALANGALE, *Engliſh*, in *Botany*. See CYPERUS.

GALANT. See GALLANT.

GALANTHUS, in *Botany*. See SNOW-*drop*.

GALARCIDES, or GALARICTIS, in *Natural Hiſtory*, a name uſed by the *Weſtern of the Middle Ages*, for a ſtone, to which they attribute great virtues. It is evidently only a corrupt way of ſpelling the word GALACTITES.

GALATEA, in *Mythology*, a ſea nymph, the daughter of Nereus and Doris, thus called on account of the fairneſs and beauty of her complexion. See NEREIDS and NYMPH.

GALATIANS, *Epiſtle to the*. See EPISTLE.

GALAX, in *Botany*, a genus of the *pentandria monogynia* claſs: the characters of which are, that the calyx conſiſts of a ten-leaved perianthium, the corolla of a ſingle bowl-ſhaped petal, and the fruit is a ſingle-celled, double-valved, elaſtic capſule. There is only one ſpecies. Linnæus.

GALAXIUS, in *Natural Hiſtory*, a name by which many of the ancients have called the MOROCHTHUS, or French chalk.

GALAXY, in *Aſtronomy*, that long, white, luminous track, which ſeems to encompaſs the heavens like a ſwath, ſcarf, or girdle; and which is eaſily perceivable in a clear night, eſpecially when the moon does not appear. The Greeks call it γαλαξιας, *galaxy*; of γαλα, γαλακτος, *milk*; on account of its colour, and appearance. The Latins, for the ſame reaſon, call it *via lactea*; and we, *the milky-way*.

It paſſes between Sagitrary and Gemini, and divides the ſphere into two parts. It is unequally broad, and in ſome parts is ſingle, in others double.

The ancient poets, and even philoſophers, ſpeak of the *galaxy* as the road, or way, by which the heroes went to heaven.

Ariſtotle makes it a kind of meteor, formed of a croud of vapours, drawn into that part by certain large ſtars diſpoſed in the region of the heavens anſwering hereto.

Others, finding that the *galaxy* was ſeen all over the globe, that it always correſponded to the ſame fixed ſtars, and that it tranſcended the height of the higheſt planets, ſet aſide Ariſtotle's opinion, and placed the *galaxy* in the firmament or region of the fixed ſtars; and concluded it to be nothing but an aſſemblage or an infinite number of minute ſtars.

Since the invention of the teleſcope, this opinion has been abundantly confirmed. By directing a good teleſcope to any part of the milky way, where, before, we only ſaw a confuſed whiteneſs; we now deſery an innumerable multitude of little ſtars. Theſe ſtars are ſo remote, that a naked eye confounds them: the like we obſerve in other ſpots, called *nebuloſæ ſtellæ*; which, when examined with the teleſcope, are diſtinctly perceived to be cluſters of little ſtars, too ſmall to affect the eye ſingly. See STAR.

M. le Monnier not being able to diſcover more ſtars in this ſpace than in the other parts of the heavens diſputes the opinion above recited as to the reaſon of the whiteneſs, and ſuppoſes that this and the nebulous ſtars are occaſioned by the ſame kind of matter. Inſt. Art. p. 60. See MILKY WAY.

GALBANETUM, a compoſition, or preparation, of galbanum formerly preſcribed, but now much out of uſe.

GALBANUM, in *Pharmacy*, a gum iſſuing from an inciſion in the root of a ferulaceous plant, called, in Latin, *ferula galbaniflua*, growing in Arabia, Syria, &c. See BUBON.

The word is derived, according to Matthiolus, from the Hebrew *chelbenah*, *fat*.

There are two kinds of *galbanum*: the one in grains, or tears; the other in a coarſe maſs. The firſt is to be choſen of a golden yellow without-ſide, but much paler within; of a bitter taſte, and ſtrong diſagreeable ſmell: for the ſecond, take that which is fulleſt of tears, very dry, clear, and not ſtinking. This laſt is eaſily ſophiſticated with broken beans, roſin, and gum ammoniac, which it reſembles in its medical virtues as well as ſenſible qualities, being leſs efficacious in aſthmatic diſorders, and more ſo on account of its ſtronger flavour, in hyſteric caſes. It forms with water, by trituration, a milky liquor, but does not perfectly diſſolve in water, vinegar,

vinegar or wine. Rectified ſpirit takes up more than either of theſe menſtrua, but not the whole: the tincture is of a bright golden colour. A mixture of two parts of rectified ſpirit and one of water diſſolves all but the impurities, which are conſiderable. The beſt way of purifying it is to include it in a bladder, and keep it in boiling water, till it becomes ſoft enough to be ſtrained, by preſſure, through a woopen cloth: its eſſential oil will be thus preſerved, which is carried off in evaporation both by water and ſpirit. The eſſential oil of *galbanum*, diſtilled with water, riſes to the ſurface, of a yelloviſh colour, and in quantity about the twentieth part of its weight. The empyreumatic oil is of a blue colour, and changes in the air into purple. Lewis and Neumann.

Galbanum is of an emollient and reſolutive nature; good in all hyſteric caſes, and in aſthmas, and inveterate coughs: it provokes the menſes, and brings on delivery; but it is chiefly uſed externally, in plaiſters for the belly, which it alſo ſoothes, in what way ſoever applied.

GALBULA, in *Ornithology*, the name of a bird of the thruſh kind, common in Italy and Germany, very remarkable for the elegant ſtructure and hanging of its neſt; and thence called by ſome *picus pendulus ſuſpenſus*, and by others *oriolus*, *coloreus*, and *iterus*, being ſuppoſed to be the ictterus, or jaundice-bird of Pliny, and the old writers. This bird is ſomewhat larger than the common thruſh; its beak is a finger's breadth long, and red; its wing-feathers are black, but ſome are tipped, and others edged with white; others are varied with yellow, and the reſt are an extremely bright and beautiful yellow. The female is leſs beautiful, the yellow being more ſhaded with black and brown. The *galbula* feeds on inſects, and is in moſt places very much eſteemed at the table, but is no where to be had at all ſeaſons, being a bird of paſſage.

GALE, in *Botany*. See *Sweet* WILLOW.

GALE, a *Sea Phraſe*, for the blowing of the wind.

When the ſea is not blown ſo hard, but that a ſhip can carry her top-ſails a trip, that is, hoiſted up to the higheſt, they ſay it is a *loom gale*.

When it blows very ſtrong they ſay it is a *ſtiff gale*, or, at leaſt a *freſh gale*; but when it blows ſo hard and violently, that a ſhip cannot bear any tail, they ſay it blows a *ſtorm*.

When two ſhips are near one another at ſea, and there being but little wind blowing, one feels more of it than another, they ſay the ſhip *gets* away from the other.

GALEA, or GALERUS, among the *Romans*, was a light caſque for the head, generally made of the ſkin of ſome wild beaſt, in order to appear the more terrible. Thus Virgil,

—— *ſubnixus ſpet de pelle galerus.*

The *galea* was alſo a head-piece, coming down to the ſhoulders, commonly of braſs, and ſometimes of iron; the lower part was called *buccula*, and on the top was the creſt.

GALEA, in *Natural Hiſtory*, the name of a genus of the *echinodermata*, or ſea-hedgehogs, whoſe ſhape is that of a large elevated helmet, compoſed of ſeveral tranſverſely-joined plates, or aſſiſe, and covered with very ſmall and rough tubercles, in the ſhape of little granulæ. This genus, when foſſile, is called in Engliſh the helmet-ſtone, and is marked with ten rows of double lines, either crenated, or punctuated, and running from the top to the baſe; the anterior ones being much longer than the reſt.

Of this genus there are three known ſpecies, viz. 1. The ſcutated headed one, which has on its ſummit an oblong pentagonal plate like a ſhield. 2. The naked headed one without this ſhield. 3. That with the tæniæ laurated, and ſhewing that they have been once of the variolated kind. Klein's Echinod.

GALEA *Piſcis*, in *Ichthyology*, a name given by Geſner, and ſome other writers, to the fiſh called by other writers *muſtela alba*, and by Artedi reduced to the genus of the *blennt*. It is the BLENNUS, with four bifid beards under the throat.

GALEA *Ventorum*, in *Zoology*, a name given by ſome authors to the common MUSTELA.

GALEANTHROPIA, of γαλεη, *cat*, and ανθρωπος, *man*, in the writings of the *Ancient Phyſicians*, a term uſed to expreſs a ſpecies of madneſs, in which the patient fancied himſelf a cat, and endeavoured to perform all the motions of that animal.

GALEARII, in *Antiquity*, *helmet-bearers*, a name the Romans gave to the black guards or ſervants of the ſoldiers. See Negetius iii. 6. and Salmaſius on the third chapter of the life of Adrian by Spartian.

GALLEASSE. See GALLEY.

GALEATÆ *flowers*. See FLOWERS.

GALEETTO, in *Ichthyology*, the name of a fiſh of the alauda kind, called by Rondeletius, *alauda non noſtrata*, and by Engliſh the mulgrance and the bullerel. It is a ſmall fiſh of a greeniſh yellow, or olive colour without any variegation in ſome, but in others a number of faint blue tranſverſe lines are diſpoſed on the back, the ſides, and the fins; the intermediate ſpaces between theſe lines on the back are of a reddiſh brown, and in ſome two olive-coloured and browniſh lines run longitudinally down the back. The colours, in ſhort, vary extremely in this fiſh. It is very full of ſize, and lives, like the eel, many hours without water. It is caught among rocks and ſtones about the ſhores in the Mediterranean, and alſo in our own ſeas. Willoughby's Hiſt. Piſc. p. 103. Artedi reduces this fiſh to the genus of the blenni, and diſtinguiſhes it by the name of the *blennus* having the upper jaw longer than the under, and the top of the head acuminated.

GALEGA, in *Botany*. See GOAT'S *Rue*.

GALENA, a name given by *Mineralifts* to a ſpecies of poor lead-ore. It was alſo the original name given by Andromachus to the theriaca, from its effect in bringing on a pleaſing calm over the blood and ſpirits on taking it.

GALENA *inanis*, in *Mineralogy*, a name given by authors to a glittering ſubſtance, very much reſembling ſome of the plated ores of lead, but really containing none of that metal. It is more uſually called mock-lead, and blende or BLINDE.

GALENIA, in *Botany*, a genus of the *octandria digynia* claſs: its characters are theſe. The flower hath no petals, but eight hairy ſtamina, of the length of the empalement. In the centre is ſituated a roundiſh germen; and the empalement afterwards becomes a roundiſh capſule with two cells, containing two oblong angular ſeeds. We know but one ſpecies of this genus, which grows naturally at the Cape of Good Hope. Miller.

GALENIC, or GALENICAL, *medicine*, is that manner of conſidering and treating diſeaſes, founded on the principles of Galen, or introduced by Galen.

Claud. Galen was of Pergamus in Aſia, the ſon of Nicon, a famous geometrician, and architect; and was a pupil of Satyrus and Pelops, two able phyſicians. He was born under the emperor Adrian, in the year of Chriſt 131, and firſt diſtinguiſhed himſelf at Athens, then at Alexandria, and laſtly at Rome; where he wrote a great deal, and where he alſo *died*.

He is ſaid to have compoſed two hundred treatiſes, wherein there are one hundred and ſeventy ſtill extant. There have been twenty-three ſeveral editions of this author. The firſt is that of Venice, in folio, in the year 1525, but the beſt is that of Paris, in thirteen volumes in folio, Greek and Latin, publiſhed in 1639.

This author collecting and digeſting what the phyſicians before him had done, and explaining every thing according to the ſtricteſt doctrine of the Peripatetics, let phyſic on a new footing: he introduced the doctrine of the four elements; the cardinal qualities, and their degrees; and the four humours, or temperaments.

GALENIC is more frequently uſed, as contradiſtinguiſhed from *chemical*.

In this ſenſe, *Galenical medicine*, and *Galenical pharmacy*, are thoſe which proceed upon the eaſier preparations of herbs, roots, &c. by infuſion, decoction, &c. and attain their ends, and make their remedies effectual, by the combining and multiplying of ingredients: in oppoſition to the chemical medicine, or pharmacy; which torture the materia medica by fire, and draw their more intimate and remote virtues by elaborate preparations; as calcination, digeſtion, fermentation, &c.

Medicine was wholly *Galenical* till the time of Paracelſus. Gebet, indeed, and after him Raymund Lully, Arnoldus de Villa Nova, and Baſil Valentine, made ſome attempts to apply chemiſtry to medicine; eſpecially the laſt of them; but no great advance was made. Paracelſus, and after him Van Helmont, altered the whole body of medicine; exploded *Galeniſm*, and the Peripatetic doctrine, and rendered medicine almoſt wholly chemical.

The late improvements in philoſophy have reformed and retrieved the *Galenical* medicine, which, however, has now little of *Galen's* in it. It is become all mechaniſm, and corpuſcular; inſtead of qualities and *degrees*, every thing is now reduced to mechanical affections; to the figures, bulks, gravities, &c. of the component particles, and to the great principle of attraction.

GALENICAL *phyſicians*. See PHYSICIANS and GALENISTS.

GALENION, the name of an anodyne cataplaſm, preſcribed by Ægineta.

GALENISTS, a denomination given to ſuch phyſicians as practiſe, preſcribe, or write, on the *Galenical* principles.

The *Galeniſts* ſtand oppoſed to the *chemiſts*. The ma-

toris medicæ of the firſt. Is chiefly of the vegetable kind, the viruſes of which they procure by the more ſimple and eaſy means, and ſeldom go beyond decoction; the latter take in minerals, ſalts, ſtones, and even metals, and ſumimetals: theſe, they hold, afford more efficacious remedies; and their virtues are procured by long, artful, laboured proceſſes, which, with the help of fire, are obtained more pure, and in a leſſer compaſs.

At preſent, the *Galeniſts* and chemiſts are pretty well accommodated; and moſt of our phyſicians uſe the preparations and remedies of both.

GALENISTS, or GALENISTES, are alſo a branch of Mennonites, or Anabaptiſts, who take in ſeveral of the opinions of the Socinians, or rather Arians, touching the divinity of our Saviour.

In 1664 the WATERLANDIANS were divided into two parties, of which the one were called *Galeniſts*, and the other APOSTOLIANS.

They are thus called from their leader, Abr. Galenus, a learned and eloquent phyſician of Amſterdam, who conſidered the Chriſtian religion as a ſyſtem, that laid much leſs ſtreſs on faith than practice; and who was for uniting into the communion of the Mennonites, all thoſe who acknowledged the divine origin of the books of the Old and New Teſtament, and led holy and virtuous lives.

GALEOBDOLON, in *Botany*, the name of a genus of plants deſcribed by Dillenius in his Hiſtoria Eithamenſis, and ranked by Linnæus under the genus of GALEOPSIS.

GALEOLA, in *Natural Hiſtory*, the name of a genus of the *teſtaceous worms*, or ſea hedge-hogs of the galeated or helmet kind.

They have their name from the Latin *galeola*, a diminutive of the word galea, and which ſignified with the ancient Romans a drinking veſſel, made in the ſhape of a ſmall helmet. Of this genus there are three known ſpecies. 1. A papilloſe kind, covered with ſmall eminences. 2. An undulated kind, with its ſtrie reſembling waves. 3. The ſmooth kind. Klein.

GALEOPSIS, in *Botany*. See *Stinking Dead* NETTLE.

GALERICULATE *flowers*. See FLOWERS.

GALEUS. See *Blue* SHARK.

GALEUS *canis*, or SQUALUS *Galeus* of Linnæus. See *Canis Galeus*.

GALEUS *levis*, or SQUALUS *Muſtelus* of Linnæus, the *ſmooth hound-fiſh*, in *Ichthyology*, the name of a fiſh of the ſame genus with the *galeus ſpinax*; but differing in ſize and many other particulars. It is called the ſmooth hound-fiſh, not from any peculiar ſmoothneſs of the ſkin, for all the *galei* are rough in that particular, but by way of diſtinction from the *galeus ſpinax*, as it has no ſpines on the back. Its back and ſides are aſh coloured; its belly white; its body long and round, the end of its ſnout is obtuſe, and runs out a great way beyond the mouth and eyes. The tail is forked. It has two fins on the back, and two pair of fins on the belly. It has, properly ſpeaking, no teeth, but the jaws are both rough and ſharp like a file.

GALEUS *rhodius*, in *Ichthyology*, a name given by Athenæus and ſome other of the old writers, to a very large and delicate fiſh. Schonevelt is of opinion, that they meant by it the ſturgeon, and brings many good reaſons for his opinion.

GALEUS *acanthias*, or SQUALUS *ſpinax*, in *Ichthyology*, the name of a fiſh of the ſhark kind, called in Engliſh the picked dog-fiſh and hound-fiſh. It has a long and round body, and has no ſcales, but is covered with a rough ſkin, uſed by ſeveral artiſts for poliſhing their works.

It takes its name from a ſtrong and ſharp ſpine placed juſt before each of the back fins.

Its back is of a brownith aſh colour. Its belly white and leſs rough, its noſe conſiderably long, ſomewhat ſtuted, and rounded at the end. The pupil of the eye is black, of an elliptic form, and ſtandsathwartwiſe. The mouth is placed about the middle of the ſnout, and in its lower part; and it has two rows of ſmall teeth. It is common in the Mediterranean and the Engliſh ſeas.

GALEUS *ſtellatus*, the *ſtarred hound-fiſh*, in *Ichthyology*, a kind of hound-fiſh, remarkably ſpeckled, with white ſpots in form of ſtars.

GALEXIA, in *Ichthyology*, a name given by Galen and ſome of the other ancient writers, to the common LAMPREY.

GALGULUS, in *Zoology*. See GALBULA.

GALI, in the *Materia Medica*, a name given by ſome to the indigo, or faeculæ of the plant and uſed in dying, &c. Garcias gives us this name, and ſays, that the plant is like the mangiricque; but Cluſius tranſlating this word by ocymum or baſil, has ſtrangely perplexed the caſe: the anil or indigo plant not having any reſemblance of that herb.

GALILEANS, GALILÆI, a ſect among the ancient Jews, denominated from Judas of *Galilee*, their chief; who, eſteeming it unworthy, that the Jews ſhould pay tribute to ſtrangers, raiſed up his countrymen againſt the edict of Auguſtus, which had ordered a cenſus, or enumeration, to be made of all his ſubjects.

Their pretence was, that God alone ſhould be owned as maſter, and called by the name of the *Lord*; in other reſpects they had much the ſame doctrine as the Phariſees; but as they judged it unlawful to pray for infidel princes, they ſeparated themſelves from the reſt of the Jews, and performed their ſacrifices apart.

As our Saviour, and his apoſtles, were of *Galilee*, they were ſuſpected to be of the ſect of *Galileans*, and it was on this principle, as St. Jerome obſerves, that the Phariſees told a ſnare for him, aſking, Whether it was lawful to give tribute to Cæſar: that in caſe he denied it, they might have an occaſion for accuſing him. Vide Joſeph. Ant. Jud. lib. xviii.

GALIUM, in *Botany*. See LADIES *Bedſtraw*.

GALILEO'S *telescope*. See TELESCOPE.

GALL, a yellow, bitter juice, or humour, called alſo *bile*, ſecreted from the bloody, in the glands of the liver, and depoſited in a peculiar reſervoir, called the *gall-bladder*.

The bile contained in the *gall*-bladder, properly called *gall*, is ſomewhat different from the bile depoſited in the porus biliarius; being of a brighter yellow, a greater conſiſtence, and more bitter and acrimonious. For the reſt, the manner of ſecretion, with the qualities, uſe, &c. of the two juices, are the ſame: which ſee, under BILE.

The bile contained in the *gall*-bladder, properly called *gall*, is ſomewhat different from the bile depoſited in the porus biliarius; being of a brighter yellow, a greater conſiſtence, and more bitter and acrimonious. For the reſt, the manner of ſecretion, with the qualities, uſe, &c. of the two juices, are the ſame: which ſee, under BILE.

After all that has been ſaid about the bile by ancient and modern writers, there ſeems yet a doubt as to the true origin, and where it is generated. The commonly eſtabliſhed opinion is, that the bile contained in the *gall*-bladder has been ſiltrated into it by certain glands which are found on its inner cavity. Theſe glands, however, have been rather ſuppoſed than demonſtrated, and if writers mean by them, thoſe little protuberances found ſometimes within the cyſt, there is no certainty of their ſeparating the bile, ſince theſe glands, as they are called, are wanting in many, nay in the greater part of perfect found bodies, where the viſcera are in a good ſtate, and not affected by any obſtructions. When the world was beginning to believe that there were in reality no ſuch glands as theſe, it was ſaid that there were certain veſſels and canals which collecting the bile from the ſubſtance of the liver, carried it to the inner ſurface of the *gall*-bladder, whoſe they opened and emptied their contents into its cavity; but theſe veſſels have in reality been no more demonſtrated to exiſt than the before mentioned glands, and there have ſometimes appeared caſes, where demonſtration has in a manner appeared on the contrary ſide, to prove, that the bile is not ſeparated in the *gall*-bladder, but is brought into it from elſewhere: of this kind there is one very remarkable inſtance mentioned in the Memoirs of the Academy of Sciences of Paris:

Mr. Lieutaud, on diſſecting a marbled body, found the *gall*-bladder to extremely ſhrunk up in ſize, that he could ſcarce at firſt light believe it was the *gall*-bladder; its neck was wholly filled, and as it were plugged up with a blackiſh matter, formed into a body of a ſpherical ſhape, and compoſed of ſeveral folds, or layers, in the manner of thoſe ſtones which are not unfrequently found in the *gall*-bladders of different animals; and the other part of this body of it, which was alſo much the largeſt, was contained in a bag made by the ſeparation of the two membranes of which the *gall*-bladder is naturally compoſed; this contained no fluid matter, except a few drops of a very clear water; and its inner ſurface, which was perfectly white, did not appear ever to have contained any bile; the cyſtic canal, and the biliary pore, were very much dilated; and the ſtate of full of bile as it could be, and the whole ſubſtance of the liver was very ſound, and in a ſtate of perfect health. Now if either of the glands in the inner membrane of the *gall*-bladder ſeparated the bile, or if any veſſels ſeparated it from the liver, and conveyed it immediately into that reſervoir by apertures in its inner ſurface, in either of theſe caſes all this might have been done in the bladder, though its neck were thus ſtopped up, but on the contrary there was no bile found there, and it ſhould appear very plainly from this, that the bile muſt have ſome other origin, ſince it ſeems to be conveyed into the *gall*-bladder no other way than through its neck. Mem. Acad. Scienc. Par. 1735.

The human bile taken out of the bodies of thoſe who died of the plague at Marſeilles, was alſo found to be of a blackiſh, or deep green colour. On the mixing ſpirit of vitriol with it, it always became of a fine green, which colour never changed in it: and when ſal, or oil of tartar were mixed in it, it always became yellow. Spirit of nitre added to it turned it black, but the colour

four soon faded. This bile poured into a wound made in the leg of a dog, would always render him drooping, dull, and not caring to eat, and all the dogs on which the experiment was tried, died within about four days, with all the circumstances of a genuine plague upon them. Philos. Trans. N° 179.

If half an ounce of alum in powder be added to a pound of ox-*gall*, and the whole stirred a little together, there rises immediately an ebullition with a considerable effervescence, and the whole becomes thick and turbid like dung, and of a greenish yellow colour; but after a while, the *gall* will be precipitated, and its thicker parts separating themselves and falling to the bottom, the remainder will become of a clear hue and a reddish colour. After this has stood five or six days, separate the clear liquor from the faeces at bottom, and from what foulness swims at top, and set it in the sun for three or four months in a vial well stopped; there will at the end of this time be found another precipitate at the bottom of the vial, and on the surface of the liquor, there will gradually gather together a white and hard fatty matter, and the red colour of the liquor finally will change into its primitive yellow again; and what is very remarkable, the whole will have the smell of boiled crayfish.

The observation that there is contained in this red liquor of the *gall*, though seemingly perfectly clear, a white fatty matter like fuet, and that on the separating of this white matter, the red liquor loses its colour, and retains its primitive yellow together, proves that the substance naturally contained in the *gall*-bladder, is a kind of liquid fuet.

The liquor of the *gall* appears red after its first precipitation, and loses this colour again by degrees as the *fat* becomes separated from it; the reason of this is, that almost all solutions of oily or fatty bodies are red, be the menstruum what it will, and this being one of those solutions must be red so long as it continues such, that is, so long as the fat remains suspended in it; but as soon as the fat is separated, the cause of the red colour ceases, and the liquor becomes yellow.

This depurated liquor of *gall* is one of the greatest of all remedies for freckles in the face: the manner of using it is this: mix together equal parts of it, and of oil of tartar per deliquium: to a dram and a half of each of these, add one ounce of river water, mix them well by shaking, and keep them in a vial well stopped: the end of the fingers being wetted with this, is to be touched upon the freckled part, and this repeated three or four times a day, letting it dry on; at length the part will look red, and there will be a sort of tickling sensation felt in it; and after that, the skin will become scurfy, and both that and the freckles will fall off. If this does not succeed the first time, it is to be repeated, and it will clear the face for six or eight months, at the end of which time it is to be used again. Mem. Acad. Par. 1709.

The *gall* of divers animals is recommended for divers uses. That of a hog is said to make the hair grow; and deterges and heals ulcers of the ears: that of a lamb is recommended for the epilepsy: that of the pike, for intermitting fevers: that of the carp clears and strengthens the sight: that of the eel has been administered, as it is said, with good success, for opening obstructions of the viscera, promoting urine, the menses, and labour-pains. Boerhaave relates that he has cured pale ricketty children by pills made of the *gall* of the eel and pike; that the medicine operated powerfully by urine, and that the belly, before swelled, subsided surprisingly: that of a kid, mixed with the white of an egg, bread, and oil of bays, and applied in form of poultice on the navel, has been extolled an approved remedy for a quotidian ague: that of a cock and a bullock, are reputed good in discases of the eyes, and to take away freckles, and other disfigurements of the skin; that of a roe-buck, or hare, deterges and carries off clouds, specks and cataracts of the eyes; that of the boar, externally applied, is resolutive, and good in scrophulous tumors; that of the sheep, and partridge, serve to deterge and clean ulcers of the eyes. Fr. Roger adds, that the Mahometans of Palestine use no other remedy against poisons, but seven or eight drops of the *gall* of a boar.

When these fluids are employed only for external purposes, a mixture of ox-*gall* with camphorated spirit of wine is said to be an useful embrocation for sprains, bruises, rheumatic pains, &c.

GALL-BLADDER, *vesicula*, or *folliculus fellis*, is a membranous receptacle, in figure somewhat like a pear; situate at the lower margin of the liver, on the concave side; being about the bigness of a pullet's egg. See *Tab. Anat. (Splanch.) fig.* 1. *lit. c. fig.* 5. *lit. c. (Angeol.) fig.* 1 *n* 34.

The *gall bladder* adheres to the liver, both by its vessels which it receives from it; and likewise by its membranes, whereof the external is common with that of the liver. The lower part, which hangs out of the liver, rests on the pylorus of the stomach, which it dyes yellow with the *gall* transuding through its membranes.

Its fundus is raised by a fulness, and depressed by the emptying of the stomach, whence that uneasy sensation which attends hunger.

Its membranes are reckoned five: an outer, or common one, from the peritonæum; an inner one, from the capsula of the porta, and pretty bituminous; and three proper ones: the first *cylindrum*, consisting of white fibres, interwoven with vessels; the second, *musculare*, consisting of a double row of fleshy fibres, the one longitudinal, the other angular; the third, or inner one, *glandulosum*, consisting of a great number of glands, like the villous villosa of the stomach, which separates a mucus that lines the inside of the *gall-bladder*, and defends it from the acrimony of the bile.

Dr. Drake, who drew a piece of dried *gall-bladder*, with a microscope, found little reason for this accurate distinction of the several spheres of fibres of the different coats, appearing to be no other than an infinite perplexity of *reticula* directly ramified.

This bladder is usually divided into two parts; the *fundus*, or bottom; and the *collum*, or neck: at the orifice of which latter is placed a ring, or circle, of muscular fibres, which serve as a sphincter to constringe the orifice of the *gall-bladder*, and hinder the too liberal discharge of the bile.

The neck of the *gall-bladder*, being prolonged, terminates in a duct, called *meatus cysticus*, or *hepaticus*, which, at about two inches distance from the *gall-bladder* is joined to the *meatus hepaticus*, and these together form the *ductus communis*. The use of the *gall-bladder* is to receive the bile, after it has been secreted in the glands of the liver, and to discharge it by the common duct into the duodenum.

There are some animals without *gall-bladders*, as deer, horses, asses, mules, camels: and among fishes, the sea-calf, and dolphin. The *gall* of these animals is inclosed in ducts, which terminate in the intestines.

Mr. Petit gives us the marks, by which a dilatation of the *gall-bladder* from the bile, making an external tumor with fluctuation, may be known and distinguished from an abcess in the liver. See Mem. de l'Acad. de Chirurg. tom. 1. and Med. Eff. Edinb. Abr. vol. ii. p. 491.

GALL *stones*. See BILIOUS *Fever* and FEVER.

GALL-*stones*. See BILIARY *Concretions* and STONE.

Gall-stones, or those concretions of earthy matter and bile that are found in the GALL-bladder, or bile ducts of beasts, are used in the arts: when these are rubbed with water, and treated as CAMBOGIA, they yield a deep warm yellow, which, on account of its brightness and durableness, as well as durableness, is very valuable. A factitious kind of *gall-stones* may be prepared in the following manner: take a quart of the fresh bile of oxen; boil it with a quarter of an ounce of clear gum arabic in a pewter veslel in *balneo Mariæ*; evaporate the whole to about an eighth, and remove the remainder into a china cup or bason, and evaporate it to dryness, collecting it into a mass as it becomes of a stiff consistence. This being more transparent, will be found of very great advantage in water-painting.

GALL is also used by naturalists to express any protuberance, or disturbion of a part of a leaf, or stalk on a tree, or plant, occasioned by an insect living and growing within it. These are all monstrous and unnatural productions of the vegetables that bear them; but they often are so regular in their formation, that they have the appearance of fruits and flowers. On examination however it will always appear, that they are fruits containing no seeds, and flowers the product of which is animals. Among the smaller insects, there are many which either in the whole state of the worm, or in a part of it, are of so tender and delicate a structure, that they cannot bear the contact of air; and others that are continually exposed to the ravage of a number of destroyers; so that by one or other of these means they could never live to arrive at maturity, or to propagate their several species. Provident nature has therefore allotted for the habitation of these the *galls* of trees and plants; they never however find excrescences ready formed, but by their own action make them for themselves. Some of these insects are produced from eggs laid by their parent animal on the stalks of leaves or plants, and as soon as ever they are hatched from these, make their way into the leaf, or stalk, and find a safe lodging in this recess, and necessary food in its juices; others are lodged even in the egg-state within the substance of the leaves and branches, and have no occasion for eating their own way in.

in. The parents of these are a peculiar race of flies, which have at their tail an instrument prepared for this purpose; with this they pierce the surfaces of vegetables, and lay their eggs in the holes they have made; so that the worms hatched from these have nothing to do, but to gnaw the tender fibres of the vegetable, and feed on the juices extravasated from the apertures they make in them. Reaumur, Hist. Inf. vol. ii. p. 176.

The manner of the production of *galls* is well described by Malpighi, in an expres treatise De Gallis. The process, as observed in the cone-*galls*, or apples on the gums of oaks, is also given us by Dr. Derham.

These cones, says that author, are in outward appearance perfectly like the gems or buds themselves, only vastly bigger; and in effect, they are no other than the gems swelled out in bulk, which naturally ought to be pushed out at length. The cause of this obstruction of vegetation is this: into the very heart of the young tender bud, which begins to be turgid in June, and shoots out in a month more, an insect, of the ichneumon fly kind, thrusts one, or more eggs; and, in all probability, some venomous ichor therewith. This egg soon becomes a maggot; which eats itself a little cell in the very heart or pith of the gem, which should be the rudiment of the branch, leaves, and fruit.

The branch thus destroyed, or, at least its vegetation obstructed; the sap that was to nourish it, is diverted into the remaining parts of the bud, which are only the scaly tegumments; and which by this means grow large and flourishing, and become a covering to the insect's case, as before they were to the tender branch.

The case lying within this cone, is, at first, but small; but, by degrees, as the included maggot increases, so does the case; till it becomes to the size of a large white pea, shaped like an acorn.

It may be added, that even nettles, ground-ivy, &c. have a kind of bulla or cases produced on their leaves, by the injection of the eggs of a fly of the same kind. These cases always grow in, or adjoining to, some rib of the leaf; and their production Malpighi and Dr. Derham describe thus:

The parent-insect, with its stiff setaceous tail, bores into the rib of the leaf, when tender, and makes way for its eggs into the very pith or heart thereof; emitting along with them a proper juice to pervert the regular vegetation.

From this wound rises a small excrescence, which, when the maggot is hatched, increases and swells on each side the leaf, between the two membranes; extending itself into the parenchymous parts thereof, till it be grown as big as two grains of wheat. In this case lies a small white, rough maggot; which turns to an aurelia, and afterwards to an ichneumon fly.

The *galls* caused by different insects have a very different internal structure, some of them have only one large cavity within, in which a number of the animals live in community, others have several small cavities with communications between each, and others have different numbers of little cellules each separate, and having no communication with the others: there are sometimes a hundred of these cellules in one *gall*, sometimes only two or three; and finally, there are others in which there is only one cavity inhabited by one insect. The creatures of these two last kinds, live in perfect solitude during the worm state, and can have no knowledge of any other living creature besides themselves, till they have passed through the intermediate state of chrysalis, and become winged animals like those to which they owed their origin, and are ready to lay eggs themselves.

The general division of *galls* into these classes, admits of a vast number of subdistinctions under each, from the different figure and consistence of the several species. Some of them are so hard, that they equal, or exceed the hardness of the wood of the tree they grow upon; and when cut, appear composed of fibres, much more densely and closely arranged: others are soft and spongy, and resemble some of the tender fruits in appearance. The first kind are usually called *galls*-nuts, and the latter apple-*galls*, or berry-*galls*. The common *galls* used in dying, are of the first kind, and what are called oak-apples, and oak-grapes are of the latter. The oak produces several of this last species of *galls*, some of which are oblong, others round, resembling grapes, gooseberries, and other fruits; these are also usually beautifully coloured, some being of a bright red, others of a bright yellow. These *galls* of the oak, are of the austere taste of the juices of that tree; but those of other plants, are often well tasted. There is a species of sage, well known by the name of apple-sage, the leaves of which afford a lodging to the worm of a peculiar species of fly, and this *gall* grows to a very considerable size, so as to have obtained the name of an apple from its resemblance to this fruit; these are eaten by the people of the eastern nations, and are commonly sold in the markets of Constantinople, and other places. A plant very common with us, the ground-ivy, has the same property; its leaves are often loaded with *galls* on their under side, which are very green and juicy, and of no disagreeable taste. Mr. Reaumur gives us an account of their being one year so plentiful in the neighbourhood of Paris, that the poor people eat them, both raw and boiled, as food. See *Tab. of Insects*, N° 25. seq. Reaumur, Hist. Inf. vol. vi. p. 182.

The round *galls* are by far the most numerous class of all others; but these have great differences in their appearance: some are perfectly smooth on the surface; others are very rough and knobby; some adhere immediately to the leaf or stalk of the vegetable; and others are placed on a longer or shorter pedicle. Some are whole on the surface, which shew that the creature by which they are formed is still contained in them, and others are perforated, so that the animal has escaped.

There are two principal kinds of *oak-galls* in our shops, and used in DYING, making INK, STAINING, &c. one said to be brought from the Levant, and the other from some of the southern parts of Europe, particularly Sicily and Romania. They are nothing else than the cases of insects, formed of the juices of the oak-tree, issuing out through small wounds made by these insects, in the manner already described. See an account of these insects in Philos. Trans. N° 245. and *Gall-insect supra*. These excrescences are not formed on any particular species of the oak-tree; for Mr. Ray says, that he has seen them on the same kind of oak with that which is common here. The first kind, called Aleppo *galls*, and in the shops of the dry-salters blue *galls*, are generally of a bluish colour, or of a greyish or blackish verging to blueness, unequal and warty on the surface, hard to break, and of a close compact texture. The second kind, commonly called white *galls*, are of a pale brownish or whitish colour, smooth, round, easily broken, less compact, and of a much larger size. The two sorts differ in strength, but in other respects they appear to be of the same quality. The Aleppo or blue *galls* are the strongest; two parts of these are reckoned by the workmen to be equivalent to three of the white, and Dr. Lewis apprehends that the difference in their strength is greater than in this proportion. The astringent and colouring matter of *gall* is dissolved and extracted from the subject both by water and spirit of wine, and does not exhale in the evaporation of the liquors by heat. From sixteen drams of *galls* fourteen drams were extracted by water, and from the same quantity twelve drams and two scruples by spirit.

Galls, with regard to their medicinal use, are found to be very astringent, and good under proper management in diarrhœas, dysenteries, and hæmorrhages of all kinds. They have also a great virtue as a FEBRIFUGE, and are often found to cure an intermittent. In fevers half a dram or more of the powder of Aleppo *galls* may be given for a dose. They are also used externally as a strengthener, and astringent: a decoction of them is applied with success by way of fomentation in *procidentia of the anus*, and has been injected in the fluor albus with great success.

Galls may be made a very useful test for iron in the several species of vitriols; for it is certain that an infusion of *galls* will become black with a solution of any vitriol that contains iron, and not at all so with such as contain only copper, as the common blue vitriol and the like.

Dr. Lewis observes, that if a decoction or infusion of *galls* is drop into a solution of this vitriol, largely diluted with water, the first drops produce bluish or purplish red clouds, which mingling with the liquor tinge it uniformly of their own bluish or reddish colour. With distilled water, or the common spring waters, the mixture is always blue; but if the smallest portion of alkaline salt be dissolved in the water, or if the water is in the least degree putrid, the colour produced will be purple or reddish. If more of the astringent infusion be added to the blue or purple liquors, they will deepen to a black, which will be more or less intense according to the degree of dilution: and the colouring matter may be separated from the liquors, unless they are of a full blackness, by dilution with water and deposition. The separation may be retarded or prevented, as is done in the preparation of ink, by adding some mucilaginous matter, as gum Arabic. This coloured matter is evidently a ferruginous precipitate; for, although it cannot be attracted by a magnet, this property may be given to it by a slight calcination. This precipitate is soluble by acids, as in the case of inks, whose colour is hereby destroyed, but it may be restored by the addition of alkalis. Lewis's Com. Phil. Techn. p. 344, &c.

GALLS, *ben*, in *Natural History*, the name given by authors to a very singular kind of *galls*, of a conic figure, with a conic top, or cover resembling a wooden box, and enclosing a white worm in the manner of the other vegetable lodgments of the same kind: this sort of *gall* is found only on the leaves of the LIME-TREE. Reaumur.

GALLS, *branches*, a species of *galls* found on the branches of the common wild bramble. These are often no other than ramifications of the stalk, for the space of an inch, or thereabout, which sometimes form only so many thick cylindric pieces; at other times they are of the shape of an olive; and sometimes they affect only one side of the branch: in all cases, however, the tumid part, or *gall*, is much harder than the other parts of the branch, which are in their natural state. They are inhabited by a great number of worms, of an oblong figure, and yellow colour, which have a sharp point, of a brown colour, and of the hardness of iron, proceeding from the extremity of the head, with which they tear and break the woody fibres, and near its end there is a slit, which is the mouth of the creature, and serves for receiving and conveying into the stomach the fragments of wood which it breaks with the point. Reaumur.

GALLS, *broom*. See BROOM.

GALLS, *lime*. See LIME.

GALLS, *mushroom*. See MUSHROOM.

GALLS, *gooseberry*. See GOOSEBERRY.

GALLS, *grape*. See GRAPE.

GALLS, *oak-leaf*. See OAK-*leaf gall*.

GALLS, *rose*. See ROSE.

GALLS, *willow*. See WILLOW.

GALL, *wind*. See WIND.

GALL-*insect*, in *Natural History*, the name of a class of insects, so called, from their resemblance to small *galls*, or vegetable protuberances of a like kind upon trees. They are indeed so like these substances, as to have been by many mistaken for them, and thought not of the animal, but of the vegetable kingdom. These insects pass a very great part of their life, even many months together, fastened against the leaves or stalks of plants, without any appearance of life or motion, and this is the time to which they acquire their stated growth. They are in this state as immoveable as the branch they are fixed on, and seem to make a part of it. Their exterior form is remarkably plain and simple, and the more the creature increases in growth, the less appearance of life it shews; and even when it has acquired its maturity, and is in a condition to deposit its eggs for the propagation of its species, it then appears least of all of an animal form, and more, than in any other state, resembles a *gall*, or such vegetable protuberance. Not only the vulgar and incurious have been deceived by this appearance, but the accurate count Marsigli, among others, after very attentively examining the *gall-insects* of one species, remained seemingly convinced that they were real vegetable excrescences.

They are usually found on the stalks and branches of trees, shrubs, and perennial plants. They are very various in size, shape, and colour.

These creatures have so little to attract the observation even of the curious, that they might probably have remained much longer unregarded, were it not that they multiply so excessively all on some fruit trees. The peach-trees, in particular, are sometimes in a manner covered with them, and these of more than one species; some of the globular kind, and others of the boat figure. The branches thus covered look rough and scabby, and the gardeners, sensible that whatever the things were, they must be nourished at the expence of the juices of the tree, have attempted to destroy them. The leaves and fruit of these trees are often blackened by the wet that has run off from these insects; and our orange-trees, which are frequently full of them, first fixed up the attention of the more careful observers of them to clear them away: these are principally of that kind, whose form is that of the inverted boat. Messrs. de la Hire and Sedileau were at the pains of making a set of observations, of a very curious kind, concerning them; these gentlemen call this species the *orange-tree-bug*, a name by which the gardeners also call them, though they have nothing in common with any known species of that animal. See the Memoirs of the Academy of Paris, 1693. If many of the species of these little animals, however, do mischief to our fruit-trees, there are some other kinds of them, the value and use of which may very well make us amends; for it is from one species of these little creatures, that the inhabitants of many places make such great gains, gathering a harvest of them without the trouble or expence of sowing or cultivating. The KERMES, so well-known by name, though so little truly understood, is of this kind, to which both the physician and the dyer are so greatly obliged. Reaumur's Hist. Insects, vol. iv. p. 1.

Dr. Lister was, perhaps, the first discoverer of the *gall-insect* and *proper insect* claſſes: he found these animals on the plum, cherry, vine, laurel, and many other trees; and calls them *patellæ* of those trees. He was well apprized of their animal origin, and in the year 1691 discovered that some of them would strike a carnation-red colour, with ley of ashes, which was not only a good dyer's permanent tinge. The principal kind on which he made the experiment was the semiglobular sort, which he describes as being entirely round, except when they are applied to the tree. They were of the size of half a large pea, of a chestnut colour, and of a shining surface, fattening themselves to the bark of the tree, as the limpets do to the rock, and were generally fought after by ants and other vermin.

GALL, *peach-insect*. See PEACH.

GALL, *pear-insect*. See SHELL.

GALL, *vine-insect*. See VINE.

GALL-*insect fly*, the male of the *gall-insect* species. It is a two-winged *fly* of a very particular kind. There seems a great resemblance between these flies in all the *gall-insect* claſs, and that of the PEACH-*gall-insect* may give a proper idea of all the rest. This little creature, examined with the help even of the best glasses, shews, on the under part of its head, nothing analogous to the organs of other flies, destined to convey their nourishment; nothing that in all resembles the trunks of the other two-winged flies, nor any thing that can be compared to teeth. Where the teeth, if any, ought to be placed, nothing is to be seen but two hemispheric, or more than hemispheric bodies, black and shining, and in all respects resembling eyes. If these are eyes, they are very remarkably situated; and just over against them, on the other side of the head, and near the bases of the antennæ, there are two other similar bodies, which indeed cannot be taken for any thing but eyes. It should seem that this fly has therefore no organs to receive aliments, but has two eyes in the place of such.

The want of these organs is nothing singular in the insect world, since the moths and butterflies afford us instances of it. Many of these may be seen, as soon as produced from their chrysalis, in a state to propagate their species, and deposit their eggs; and this great end achieved, they have no further occasion for life, nor any means for its support; and probably the case is the same with these flies, which as soon as loose from their shell, seek out and fecundate the females, and have after this no further use for life. It is another singularity in this species, that they are produced from their shell by their hinder part first, whereas all other species of the two-winged flies are produced with the forepart of their body first; and if we cannot say what may be the reasons for this singularity in the production of this fly, we can however easily perceive that every thing is prepared and destined accordingly for it. In the nymphs of other flies, all the legs are constantly applied close to the body, whereas on the contrary, in the nymph of the *gall-insect fly*, the legs placed next the head, or the first pair, are constantly ranged upward, and each of them embraces one side of the head; the constant position of these legs in this direction, is a proof that it is the order and course of nature in the production of the animal; nor is it without reason that they are thus placed in a species which, contrary to all the others, is to force itself backward out of its shell, since they serve very properly for the creature to push himself backward by; and as the posterior part of the case of other flies naturally and easily opens, to give passage to the animal, so the posterior part of this does. They seem also to be more than ordinarily slow in their getting out, some of them having been observed to be ten or twelve hours, from the time of the first appearance of a piece of each wing, to their perfect enlargement. Reaumur, Hist. Insect. vol. iv. p. 40.

GALLÆ. See GALLI.

GALLANT, or GALANT, a French term, signifying civil, polite, well-bred; or a person of wit and address, who does every thing with a good grace: in fine, a civil person, somewhat brighter, gayer, and more agreeable than ordinary.

It is difficult to define all the qualities annexed to the idea of a *gallant* man. It sometimes implies one who has what the French call the *bon ton*; but it generally means one who has a great devotion for the fair sex, with the manners adapted to please them. The French authors are very nice on this point; they distinguish *galant homme*, and *homme galant*.

GALLANTES, among the Romans, a furname given to the priests of Cybele; whence the modern names of *gallant*,

lant, and *gallantry*, have been formed. See Mem. Acad. Inscript. vol. v. p. 427.

GALLED, *adject.* See SADDLE-*galled*.

GALLEY, in *Sea-Language*, is applied to a mast, yard, cable, &c. which is chafed and worn by friction. They are usually covered with skins, mats, canvas, &c. in those parts which are the most exposed by the rocking of the vessel, as a preservation from this injury.

GALLEON. See GALLION.

GALLERICA *lapis*, a name given by the writers of the middle ages to a species of emerald, which was larger than the finer gems of that kind, and of a pleasant green, but debased by an admixture of white.

GALLERY, in *Architecture*, a covered place in a house, much longer than broad; and which is usually placed in the wings of the buildings, and serves to walk in.

Scorel, in his architecture, derives the word *gallery* from *Gaul*, as supposing the ancient Gauls to have been the first who used them. Nicod fetches it from the French *aller*, to go; q. d. *alleries*: others bring it from *galery*, *gallery*; because it bears some resemblance thereto in respect of length. In the corrupt Latin we have *galilæa*, for the *galleries* of a monastery.

The *galleries* of the Louvre are magnificent; a *gallery* of painting; a complete apartment is to consist of a hall, antechamber, chamber, cabinet, and *gallery*.

GALLERY *also* denotes a little aisle, or walk, serving as a common passage to several rooms placed in a line, or so.

The *gallery* of a church is a kind of continued tribune, with a balustrade, built along the sides or lower end of a church, to make it hold the more people; and, in the Greek churches, to separate the women from the men.

GALLERY, in *Fortification*, a covered walk, or passage, made across the ditch of a town besieged, with timbers fastened on the ground, and planked over. See Tab. Vii. *Fortif. fig.* 40.

The sides of the *gallery* are to be musquet-proof, and to consist of a double row of planks, lined with plates of iron; and the top is sometimes covered with earth, or turf, to hinder the effect of stones, artificial fires, &c. of the enemy.

Galleries are chiefly used to secure and facilitate the miners approach to the face of the bastion, over the moat, which is already supposed filled up with faggots and hoops, and the artillery of the opposite flank dismounted. Sometimes this is called a *traverse*.

GALLERY, in *Gardening*, is a kind of covered walk, which is to be made in the following manner. A line is first to be drawn to the length of the intended *gallery*, and this is to be planted with hornbeam, which is to be the foundation of the *gallery*. These require no farther care than to be fenced a little, and sometimes digged about, as there may be occasion. But the chief curiosity is in the ordering the four-part of the *gallery*, and forming the arches. The pillars of the portico, or arches, must be placed at four feet distance from one another, and the *gallery* must be twelve feet high, and ten feet wide, that there may be room for three persons to walk abreast in it. When the hornbeams are grown to the height of three feet, the distance of the pillars will be regulated, and the ground-work of the *gallery* finished, the next thing is to form the frontispiece; to perform which, the hornbeam must be slope between two pillars at the height, and a trellis, made for that purpose, must be run up, which forms the arch. As it grows up, those branches which out-top the others must be levelled with the shears; and in time they will grow very strong, and may be kept in regularity by the shears. Portico *galleries* may be covered with lime-trees.

Galleries in general have been always but lightly esteemed in England: they were once very much in repute in the gardens of Italy, and other hot countries, but now they are got out of credit even there. Miller.

GALLERY *of a mine* denotes the *branch*, or that narrow passage under-ground, leading to a mine carrying on under any work designed to be blown up.

The besiegers and besieged do each of them carry *galleries*, or branches under ground, in search of each other's mines; and these sometimes meet and destroy each other.

GALLERY *in a ship*, is a kind of balcony, made upon the stern, without board, into which there is a passage out of the great cabin. See Tab. *Ship. fig.* 1. lit. m. *fig.* 2. n. 98. and 101.

These *galleries* are for show, and the captain's pleasure, rather than any other benefit; for, in ships of war, all open *galleries* of this kind are to be avoided; on account of the facility of an enemy's entrance, and boarding of the ship that way.

GALLERY-*ladder*, in a *Ship*. See LADDER.

GALLERY, *whispering*. See WHISPERING *place*.

GALLEY, in *Cookery*, is the name given to roverberatory furnaces, in which several retorts may be placed at the sides of each other. They are so called, because they are oblong, and have lateral openings, in which they are supposed to resemble *galleys*.

GALLEY, in *Naval Language*, a low-built vessel, going both with oars and sails; chiefly used by the states bordering on the Mediterranean.

The *galley* is called by the Greek authors under the eastern empire *gyrus*, and *gyrus*; and by the Latin authors of the same time, *galea*; whence the modern denomination. Some say, it was called *galea*, on account of the figure of a cock or helmet, which it bore on its head or prow, as Ovid states, De Tristib. The French call it *galere*; because they say, that the top of the mast is usually cut in manner of a hat, which the Italians call *galera*. Others derive both *galea* and *galere* from a fish, by the Greeks called *galeus*, or *galea*, and by us the *fourd-fish*, whose shape this vessel resembles. Lastly, others derive *galley*, *galea*, *galere*, *galeagia*, &c. from the Syriac and Chaldee *gual* and *galla*, a man exposed on the water, or in a vessel of wood.

The largest sort of these vessels, called *galeasses*, is employed only by the Venetians. They are commonly one hundred and forty-two feet long above, and one hundred and thirty-three feet by the keel; thirty-two feet wide, with twenty three feet length of stern-post. They are furnished with three masts, and thirty-two banks of oars, every bank containing two oars, and every oar being manned by six or seven slaves, who are usually chained to it. In the fore-part they have three large batteries of cannon, of which the lowest is of two thirty-six pounders, the second of two twenty-four-pounders, and the uppermost of two two-pounders; three eight-inch pounders are also placed on each quarter. The complement of men for one of these *galleys* is generally a hundred, or twelve hundred. They are very convenient for boarding, or making a defcent on an enemy's coast, because they draw little water; and on account of their oars, they have often the advantage of ships of war in light winds or calms, by cannonading the latter near the surface of the water, by lowering their whole length with their shot, and at the same time keeping on their quarter or bow, so as to be out of the direction of their cannon. The *galley* next in size to these, called *also half-galley*, are from one hundred and twenty to one hundred and thirty feet long, eighteen feet broad, and nine or ten feet deep. They have two masts, which may be struck at pleasure, and are furnished with two large lateen sails, and five piece of cannon; they have commonly twenty-five banks of oars, as already described. Those of a size still less than these are called *quarter-galleys*, carrying from twelve to fifteen banks of oars.

All the *gallies*, both ancient and modern, are of a finer and slenderer make than ships. Formerly they made divers kinds; at present the *gallys* are all alike: all the difference between them is as to size, and nothing as to figure. They usually keep towards the coasts, though sometimes they cross the sea.

The king of France keeps up forty *gallies* for the use of the Mediterranean, the admiral thereof being a Marseilles. The general of the *gallies* bears a double anchor, placed in pale, behind the escutcheon of his arms, as a mark of his office.

Gallys in Latin are called *biremes*, *triremes*, and *quadriremes*; not on account of their having two, three, or four ranges of oars before one another, as many learned men have imagined, and particularly Scaliger and Stellus, though this latter has wrote excellently on the subject of navigation; for this were impracticable; not yet on account of their having but two or three, or four oars, for then they would want strength; but because there were two, three, or four towers, fastened to each oar, as in the *gallys* used among us; as is very well shewn by the Jesuit Dechales, in his Art of Sailing. The river was accustomed by some ancient *gallys*, represented on medals, or bas-reliefs, wherein are several ranges of rowers placed over each other; but all the mathematicians, pilots, and ship-builders, look on this as a mere vision; inasmuch as Pliny makes mention of *gallys* of fifteen, twenty, thirty, forty, nay rows of rowers; to that, if they were ranged over each other, though we were only to allow four feet for cathedrals, there would be a distance of one hundred and forty feet between the lowest rowers and the highest; and yet we are assured, that the highest vessel ever built was only seventy-two feet high.

Scaliger affirms, that the first THIRTEMES, or *gallys* of three ranges, was built at Corinth; and is of opinion, that what Pliny calls *long ships*, were what we call *gallys*; the first whereof was that of the Argonauts. Vegetius mentions a *galley* of five decks; and Mennon, another with eight, and only one man to each oar. See ENNEREIS.

GALLEY,

GALLEY, *captain*, is the principal *galley* of a fleet, commanded by the captain-general of the *galleys*: in France the *royal galley* is the first.

GALLEY, *patron*, denotes the second *galley* both of France, Tuscany, and Malta.

The second general of the *galleys* is always on board the royal *galley*; and the lieutenant on board the patroon. * The terms peculiar to *galleys* are very numerous, and make a new system of sea-language, different from that used in ships.

Mont-de Berzi, an ancient officer on board the king of France's *galleys*, engaged himself in writing a new dictionary of the dialect of the *galleys*.

GALLEYS, *condemnation to the*, is a penalty imposed on criminals and delinquents, particularly in France; whereby they are adjudged to serve the king, or state, as slaves on board the *galleys*, either for ever, or for a limited time.

Condemnation to the *galleys* for ever imports confiscation of lands, goods, &c. for in France, that which confiscates the person, confiscates the goods.

A man condemned to the *galleys* for perpetuity, is dead in a civil sense. He cannot dispose of any of his effects; cannot inherit; and, if he be married, his marriage is null; nor can his widow have any of her dower out of his goods.

The ecclesiastical courts cannot sentence to the *galleys*; it is out of their jurisdiction.

By an ordonnance of Charles IX. in 1564, the judges are enjoined not to condemn a criminal to the *galleys* for less than ten years: and Hen. III. by another of 1579, enjoins the captains not to detain their *galley*-slaves after their time is expired. But neither of these laws are now observed.

GALLEY, in *Printing*, a wooden frame, or instrument, formed of an oblong square board, with a ledge on three sides, and a groove to admit a false bottom called a *galley*-face, into which the compositor empties the letters out of his composing-stick, as often as it is filled.

The *galley*, when filled, contains the matter of one page; and when they have composed as many pages as are required for a whole sheet, half sheet, or the like, they impose them, i. e. they take the several pages out of the *galley*; put form into a chase; lock them up with the furniture; and so make forms ready for the press.

GALLEY-*half-penee*, a kind of coin, which with *sterlins* and *doublets*, were forbidden by the statute 3 Hen. V. cap. 1. It is said they were brought into this kingdom by the Genoese merchants, who trading hither in galleys, lived continually in a house near Tower-street, and were called *Galley-men*; lanching their goods at *Galley-key*, and trading with their own small silver coin, termed *galley-half-pence*.

GALLI, or GALLÆ, in *Antiquity*, a name given in Phrygia to the eunuch-priests of the goddess Cybele.

The principal of them was called *Archi-Galles*. The *Galli* were also called *Dactyli*, *Idæi*, *Curybantes*, &c. Authors are not agreed as to the reason of this denomination. Some derive the name from the river Gallus; because these priests drank of its waters, which inspired them with I know not what religious fury and enthusiasm, and deprived them of their senses to such a degree, that they mutilated themselves.

Others hold, that the first priest of Cybele having been named Gallus, the name became appropriated to all his successors. Vossius, who proposes these two opinions, seems to incline most in the latter; though Ovid, in the fourth of his *Fasti*, and Herodian, lib. i. favour the former.

When youth were initiated into this order, the custom in Syria, according to Lucian, was to throw off their cloaths, to make loud cries, and with drawn swords to castrate themselves: after which they ran about the streets, carrying in their hands the marks of their mutilation, which were thrown into a house, and in that house they put on women's dress.

These priests threw themselves into a kind of phrensy, when they performed the ceremonies of the *goddess*; apparently, in imitation of the young Attis, her favourite, whom they likewise imitated, by mutilating themselves. For authors relate, that Cybele being desperately in love with that young Phrygian, she gave him the superintendance of her sacrifices, on condition he would keep his virginity: but that soon after, forgetting his promise, he had an affair with the nymph Sangaritis; that Cybele, provoked hereat, struck him mad; that in a vehement access of his phrensy he was going to kill himself; and that the goddess, relenting, restored him to his understanding; that out of his own remorse, he castrated himself; and that after his example all the priests of Cybele from that time did the like.

Their phrensy, at the same time of the sacrifices, consisted in throwing round the head with great rapidity, and making violent contortions of the whole body: they had also drums and flutes, wherewith they played, and danced to them: as already observed under the articles CORYBANTES, and CURETES.

GALLI, *caput*. See CAPUT.

GALLI, *cribs*. See CRIBA.

GALLIAMBIC, in the *Ancient Poetry*. *Galliambic poem* is a composition in *Galliambic* verses.

GALLIAMBIC *verse*, a sort of iambic, consisting of six feet; 1. an anapæst, or a spondee; 2. an iambic, or an anapæst, or tribrach; 3. an iambus; 4. a dactyl; 5. a dactyl; and 6. anapæst.

Though not might measure the *Galliambic* verse in another manner, and make a different arrangement and combination of syllables, which would give different feet. It is certain the ancients regarded little more in the *Galliambic* verse, beside the number of measures, or intervals, without troubling themselves about the number of syllables, or the kinds of feet whereof it was composed.

GALLIAMBUS, in *Poetry*, a pleasant kind of verse, used to be sung by the Galli, priests of Cybele, in honour of that goddess.

The word is a compound of *Gallus*, a priest of Cybele, and *iambus*, a foot in the Greek and Latin verse.

Galliambus also denotes a piece or composition in *Galliambic* verses.

GALLIANA, in *Natural History*, a name given by some authors to the TURQUOISE stone. It is only a corruption of the word *callaina gemma*, a name of this stone common among the Roman authors.

GALLIARD, or GAGLIARDA, in *Music* and *Dancing*, a sort of dance, anciently in great request; consisting of very different motions and actions, sometimes proceeding *terra à terra*, or smoothly along; sometimes capering; sometimes along the room, and sometimes across.

The word is French, *gaillarde*, or rather Italian; and literally signifies *gay*, *merry*, *sprightly*. This dance was also called *Romanesca*, because brought from Rome.

Thoinot Arbeau, in his Orcheseography, describes it as consisting of five steps, and five postures of the feet, which the dancers performed before each other; and whereof he gives us the score, or tablature, which is of six minims, and two triple times.

GALLIARDA, in the *Italian Music*, the name of a rune that belongs to a dance called a galliard. The air of it is likewise in triple time.

GALLICAN *church* denotes the church of France; or the assembly or convocation of the prelates of France.

Du Pin has an express treatise of the liberties of the *Gallican* CHURCH.

GALLICAN *breviary* denotes the breviary used by the church of Agrigentum, in Sicily; which the modern writers call Breviarium Gallicanum.

The reason, no doubt, is its having been introduced by St. Gerlan, who was made bishop of Agrigentum, after earl Roger had been driven out of Sicily by the Saracens; and by the other French bishops, whom the Norman princes brought thither. See BREVIARY.

GALLICAN *liturgy* is the manner of performing divine services, anciently observed in the Gauls.

Fa. Mabillon shews wherein it differed from the Roman liturgy. 1. Liturg. Gall. cap. 5, &c.

GALLICAN *mass*. See MASS.

GALLICISM, a phrase, or construction, peculiar to the French language; or which has something contrary to the ordinary rules of grammar or other languages.

Thus, *Cet homme-ci, or-la brûche*, is a *Gallicism*, having no regular construction; and the same may be said of *Faire de la terre le fosse*; which no grammar could ever find out.

With us it is used to denote such phrases or modes of speech in English, as are formed after the French idiom.

GALLIGASKINS, in our *Old Writers*, denote wide hose or breeches, having their name from their being used by the Gascoigns.

GALLIMATHIAS, a dark, perplexed discourse, where words and things are huddled together, so as to make an unconceivable jargon.

The word is French, formed as some will have it, from *polymathia*, which signifies diversity of sciences; because such as have their memory burdened with several kinds of sciences, are usually confused, and express themselves ill. M. Huet rather takes the word *gallimathias* to have had the same origin with *villorum*; and to have first arisen at the time when all the pleadings at the bar were in latin. There was a cause, it seems, upon the carpet, about a cock, belonging to the plaintiff Matthias; the counsel, in the heat of his harangue, by often repeating the words *gallus* and *Matthias*, happened to blunder; and, instead of saying *gallus Matthiæ*, said *gallimathias*; which at length became a general name for all confused, embroiled language, and discourse.

GAL-

GALLIMAWFRY, a ragoo, hatche, or hotch-pot, made of the remains of several kinds of meats.

The word is French, *gallimaufrée*, which signifies the same.

Hence the word is also used in a figurative sense for a piece, or composition, of several different parts, ill digested and embarrassed.

GALLINÆ, in the Linnæan system of *Ornithology*, the name of a large order of birds, the general character of which is, that their beak is conic and bent; the upper mandible is arched, and extends beyond the lower; the nostrils are half covered with a cartilaginous convex membrane; the feathers of the tails are more than twelve, and the feet are cloven; but the outmost and inner toes are connected by the first joint of the middle toe by a small membrane. The DODO, PEACOCK, the *meleagris* of TURKEY, the CRAX, the PHEASANT, the *meleagris Numida*, or GUINEA-hen, and TETRAO, are of this order.

GALLINA *Guinea*. See GUINEA-*hen*.

GALLINA *Mexambicana*, in *Ornithology*, a name under which Nieremberg has described a sort of hen, which he says has not only black feathers, but black flesh, and black bones: a history Mr. Ray sufficiently explodes.

GALLINA *piscis*, in *Ichthyology*, the name of a fish of the cuculus kind, more usually known by the name of the *cornu piscis*.

GALLINACEOUS, in *Ornithology*, the name of a species of birds of the phasians kind, including the common cock and hen, the characters of which are these. The beak is short, strong, and a little crooked, proper for the picking up of corn, which is the food of the whole species; the body is large, thick, and fleshy; the wings are short and hollowed, and not calculated for much flying; they all breed a numerous progeny; they build on the ground; the young are not fed by the parent, but immediately shift for themselves; and some have long spurs behind their legs. See COCK and FOWL.

GALLINAGINIS *caput*. See CAPUT.

GALLINAGO, a general name for heath fowls, as the WOOD-*cock*, SNIPE, &c.

GALLINAGO *minor*. See SNIPE.

GALLINE, in *Ichthyology*, a name given by the Massilians to the flying-*fish*, called by authors *milvus* and *hirundo*. It is a species of TRIGLA, and is distinguished by Artedi by the name of the *trigla* with the snout somewhat bifid at the end, and the lateral lines forked towards the tail.

GALLING, in *Medicine*, *Interigo*. Children are subject to inflammations and excoriations in several parts of their bodies, particularly behind the ears, in the neck, and thighs. Those in the lower parts usually proceed from the acrimony of the urine, which sometimes frets off the epidermis, and leaves the cutis bare. The cure may be accomplished by washing the parts gently with warm water, twice or thrice a day, which dissolves and drinks up the acrimonious salts of the urine lodged therein. Nutsh ufually diffolve a little fuller's earth in the water, and apply it to the part after being well waſhed. Cerufs, chalk, or calcined flate, finely powdered, will alſo ſerve for the ſame purpoſe. But where the inflammation and excoriation are conſiderable, it is proper to uſe, by way of fomentation, a ſolution of *teutiſcii alki Rhoſis*, in plantain water, twice or thrice a day. In the mean time the parts ſhould by all means be kept dry, or prevented from rubbing againſt each other, by the interpoſition of ſoft linen rags, or the uſe of a little red deſiccative ointment, or diapompholygos, ſpread thin upon it.

Gallings, produced by the wringing of uneaſy ſhoes, are mollified and kept from ſwelling by the application of the lungs of a ſwine or lamb, warm, to the grieved part. Effectual for the ſame purpoſe, is the powder of a burnt old ſhoe ſprinkled on the place, or raw wool, or the flowers of the garden pomegranate, each of them burnt, and the aſhes ſprinkled thereon; or acacia rubbed on the galled part with vinegar. To thoſe who have tender feet apply the *emplaſtrum ex hordeo*.

For *gallings*, burns, and eruptions of *papulæ*, a moſt excellent plaſter is prepared of three ounces of lohaeg, four ounces of wax, one ounce of recent ſwine's fat, and a pound of oil of myrtle; to induce a cicatrix, omit the fat in the preſcription. Actius, Tetrab. 4. Serm. cap 67.

Baliauſtines are much commended by Oribaſius for ſpeedily cicatrizing *gallings* and old ulcers: the bark of the pine-tree, alſo, is ſaid by the ſame author to be excellent for *gallings*, being applied to the place. James's Med. Dict.

GALLING. See BARE-*galling*, SADDLE, &c.

GALLINULA, in *Ornithology*, the name of a genus of birds which ſwim on the water, and yet have not webbed feet, nor any membranes joined to their toes, to augment their breadth. The bill is thick at the baſe, ſloping to the point, the upper mandible reaching far up the forehead, and calloſe; the wings are ſhort and concave, the body compreſſed, and the toes long, diverted to their origin. The common moor-hen, and a great number of other birds, both Engliſh and exotic, are of this genus, as the water-rail, the grinetta, the ochropus, and ſeveral Braſilian birds.

GALLINULA *erythropus*, in *Ornithology*, a name given by many authors to the bird commonly called in Engliſh the RED-SHANK.

GALLINULA *hypoleucos*, in *Ornithology*, a name given by ſome authors to the becaſſine, or, as we call it in Engliſh, the SANDPIPER. See TRINGA.

GALLINULA *melanopus*, in *Ornithology*, a name given by Geſner and ſome others, to the bird more uſually known by its German name, ROTKNUSSEL.

GALLINULA *rhodopus*, *glareolus*, and *ochropus*, names by which Geſner, and ſome others, have called the common TRINGA; a bird in which the legs are, at different ages, and in the different ſexes, greeniſh, yelloviſh, or reddiſh.

GALLINULA *ſorica*, in *Ornithology*, a name given indiſcriminately by many authors to the GRINETTA, and the water-rail, both birds of the moor-hen kind, but ſmaller than the common moor-hen.

GALLION, or GALLEON, formerly denoted a large veſſel, or ſhip of war, of three or four decks.

GALLEON is now only uſed in ſpeaking of the Spaniſh fleet; the *galleons* being a part of the ſhips employed in the commerce of the Weſt Indies.

The Spaniards ſend every year two fleets, the one for Mexico, which they call the FLOTA; and the other for Peru, which they call the *galleons*.

GALLEON, *Manilla*, is a ſhip employed in the trade from Manilla to the iſland of Luconia, the chief of the Philippine iſlands, to Acapulco on the coaſt of Mexico. This ſhip ſets ſail from Manilla about July, and arrives at Acapulco in December, January, or February following. There is ſeldom more than one ſhip employed in this trade at a time; but there are three or four ſtout ſhips provided to carry on this commerce, one of which is always ready for the firſt that arrives. The largeſt of theſe ſhips is little leſs than one of our firſt rate men of war, and carries twelve hundred men; the others are of the burthen of twelve hundred ton and upwards, and carry from three hundred and fifty to ſix hundred men, with between fifty and ſixty guns. Theſe ſhips are commiſſioned and paid by the king of Spain, who pays the officers and crew; and one of the captains is called the general, and carries the royal ſtandard of Spain at the top-gallant-maſt-head. The trade from Manilla to Acapulco conſiſts of ſuch commodities, collected in China and different parts of India, as are intended to ſupply the kingdoms of Mexico and Peru. Theſe are ſpices, all ſorts of Chineſe arts and manufactures, particularly ſilk ſtockings, of which the annual ſhip uſually carries no leſs than fifty thouſand pair, with quantities of Indian ſtuffs, as callicoes, and chintz, together with other manufactures, as goldſmiths work, &c. which is performed at Manilla by the Chineſe, of whom there are no leſs than twenty thouſand who conſtantly reſide there. However this trade is not open to all the inhabitants of Manilla, but is reſtrained by regulations ſimilar to thoſe of the regiſter ſhips from Cadiz to the Weſt Indies. The value of this trade is limited by the royal edicts, as it has been ſaid by ſome, to ſix hundred thouſand dollars; but it is reaſonable to conclude that the returns of it cannot be much leſs than of three millions of dollars. The tonnage of the ſhips employed in this trade is divided into a certain number of bales of the ſame ſize, which are diſtributed among the convents at Manilla, but principally to the Jeſuits for the ſupport of their miſſions; and theſe convents have a right to embark ſuch a quantity of goods on board the Manilla ſhip, as the tonnage of their bales amounts to, or to ſell the paſſage to others. This ſhip, having diſpoſed of its effects at Acapulco, returns to Manilla ſome time in March, where it generally arrives in June; ſo that the whole voyage takes up near a year. The principal return from Acapulco to Manilla is always made in ſilver, the reſt of the cargo being conſiderably leſſened and conſiſting of cochineal and ſweet-meats, the produce of the American ſettlements, *European* uſefulneſs were for the women at Manilla, and ſome Spaniſh wines, as tent and ſherry, which are intended for the uſe of their prieſts in the adminiſtration of the ſacrament. The *galleon* in its return is much leſs incumbered with her cargo than in her paſſage thither; and therefore her crew is conſiderably augmented and her lower tier of guns is mounted, which before was carried in her hold, at leaſt till the came near cape St. Lucas and California not apprehended an enemy. Anſon's Voyage, chap. 2. p. 232—238.

Theſe are all ſhips of war, and go on the king's account; but

but they are so loaden and embarrassed with merchandizes, that, in case of an attack, they find it difficult to defend themselves.

Besides the king's *galleons*, there are usually twelve or sixteen merchant-ships, called REGISTER-ships, belonging to private persons, who obtain leave for the same, or rather buy it; there being no West India company in Spain.

The *galleons* are loaded at Cadiz, from whence they may put out at any time. They were formerly appointed to be out in January, that they might coast along the firm land, and come about the middle of April to Porto Bello, where, the fair being over, they might take aboard the plate, and be at the Havannah with it about the middle of June, where the New Spain fleet would soon join them, and they might come together more safely to Spain. For this purpose, the viceroy of Peru was to take care that the plate should be at Panama by the middle of March; the plate is fifteen days in coming from Potosi to Arica; eight days generally from thence by sea, to Callao, and twenty from Callao to Panama, taking in by the way the plate at Pisco and Truxillo. But it has been found by experience, that the month of September is the fittest for the fleet to sail; they are about two years in the whole voyage. However often or seldom the *galleons* go out, the next fleet never go out till the last are returned. When the *galleons* and flota put out together, they separate about the Antilles islands; the *galleons* for Carthagena and Porto Bello; and the flota for Vera Cruz. At their return, they rejoin at the Havannah in the isle of Cuba.

The loading of the *galleons* is always the richest: an estimate of the yearly returns or cargoes, both of the flota and *galleons*, was formerly as follows:

Of gold, the *galleons* bring yearly about two or three millions of crowns, and the flota about one. Of silver, the *galleons* bring eighteen or twenty thousand crowns, and the flota ten or twelve. Of precious stones, the *galleons* bring as follow: two hundred thousand crowns worth of pearls; two or three hundred thousand crowns of emeralds; and twenty or thirty thousand crowns worth of bezoards, amethysts, and other stones of less value: the flota brings none at all. Of wools, the *galleons* bring forty or fifty thousand crowns: the flota, none. Of quinquina, the *galleons* bring the value of twenty thousand crowns: the flota, none. Of skins and leather, the *galleons* bring seventy thousand crowns worth: the flota as much. Of Campechy wood, the *galleons* bring sixty thousand crowns worth: the flota, none. Of skins and leather from Buenos Ayres, the register-ships may bring to about two hundred thousand crowns; of cochineal, about a million of crowns; and of indigo, about six hundred thousand crowns.

By a general ordinance in Spain, it has been established that there should be twelve men of war and five tenders fitted out annually for the armada of *galleons*; eight ships of six hundred tons burthen each; and three tenders, one of a hundred tons, for the island Margarita; and two of eighty each to follow the armada. For the New Spain fleet two ships of six hundred tons each, and two tenders of eighty each; and for the Honduras fleet, two ships of five hundred tons each; and in case no flota happened to sail any year, three *galleons* and a tender should be sent to New Spain for the plate.

But the number of *galleons* has been different at different times; it has increased in time of war and diminished in time of peace.

GALLIOT, a small galley or a sort of brigantine, built very slightly, and designed only for chace.

She hath but one mast, and can both sail and row. She usually carries two or three pederero, and hath sixteen or twenty oars.

Some also call the bomb-ketches, *galliots*.

GALLITRICHUM, in *Botany*, a name by which several authors call the *herniaria glabrum*, or garden-clarey.

GALLIUM. See GALIUM.

GALLOGLASSES, a kind of militia or soldiery, in Ireland.

Camden, in his Annals of Ireland, p. 792, relates, that the Irish militia consists of cavalry, or horsemen, called *galloglasses*, or *gallowglasses*, who use a very sharp sort of hatchet; and infantry, called *kerns*.

GALLON, an English measure, for things both liquid and dry, containing two pottles, or four quarts.

The *gallon* always contains eight pints, or four quarts; but those pints and quarts, and consequently the *gallon* itself, are different, according to the quality of the things measured: the wine *gallon*, for instance, contains 231 cubic inches, and holds eight pounds, avoirdupois, of pure water; the beer, and ale *gallon*, contain 283 solid inches, and holds ten pounds three ounces and a quarter; and the *gallon* for grains, meals, &c. 272¼ inches, and holds nine pounds thirteen ounces of pure water. See MEASURE.

GALLOON, in *Commerce*, a thick, narrow kind of ferret ribband, or lace, used to edge or border cloaths.

The term is ordinarily understood of that made of wool; sometimes that of thread, or even gold or silver.

GALLOP, in the *Manege*, is the swiftest natural pace of a horse, performed by reaches or leaps; the two fore-feet being raised almost at the same time; and when those are in the air, and just ready to touch the ground again, the two hind-feet are lifted almost at once.

The word is borrowed from the barbarous Latin *salt-aria*, or *saltatoria ars*. Some derive it from *caballicare*; others from the Greek καλπαζειν, or καλπην, *to jump a horse*.

In *galloping*, the horse may lead with which fore-leg he pleases; the most usual way is that with the right, in which case the *gallop* is said to be *full*; but which soever it be, the hind-leg of the same side must follow it next, which forms an *even* or *equal gallop*; otherwise the legs are said to be *disjointed*, and the *gallop* to be *false*: to remedy which disorder, the rider must slap the horse a little on the hand, and help him on the spur on the contrary side to that on which he is disjointed.

However, this rule has not been always strictly observed: for hunting horses have been trained to lead indifferently with both legs, because it has been found, that a horse which has never been suffered to *gallop* but with his right fore-leg, has been worn out on one side, when he has been fresh and sound on the other. In order to make a stop in a *gallop* straight forwards, the rider should carefully put his horse together, without altering or disturbing the appuy, and throw his body back a little to accompany the action, and to relieve the horse's shoulders. In doing this, he should seize the time of making the stop, keeping the hand and body quite still, exactly when he feels the horse put his fore-feet to the ground, in order that by raising them immediately by the next motion which he makes, he may be upon his haunches. When horses do not put out their strength sufficiently, they should be *galloped* briskly, and then slowly again by turns, and they will thus be compelled to obey the hand and heel. In the *slow gallop*, as well as in the trot, it is sometimes necessary to close the heels to the horse's sides, which is called *pinching*; but this should be done in such a manner as not to make the horse abandon himself upon the hand, and care must be taken that he be upon his haunches, and not upon his shoulders; and, therefore, when he is pinched, he should be kept in the hand. To put a horse well together, and make him bring his hinder legs under him, the rider must close his legs upon him, putting them very much back; this will oblige him to bring his legs under him: at the same instant let the hand be raised a little to support him before, and yielded again immediately. Let him be thus supported, and leave the rein again from time to time; till he begins to play and bend his haunches, and *gallop* leaning and turning down, as it were upon them; let the rider then press him with the calves of the legs, and he will thus become quick and sensible to the touch. If a horse has too fine a mouth, *gallop* him upon sloping ground, this will oblige him to lean a little upon the hand, in order the better to put himself upon the haunches; and through fear of hurting his bars, he will be prevented from resisting the operation of the bit. If the horse is heavy in hand, *gallop* him up sloping ground; and when his appuy is too strong, this will lighten him. The *gallop* serves to assure and make steady a weak and delicate mouth, and also to supple a horse, and make him steady and active in his limbs. Grenger's Hist. and Art of Horsemanship, vol. ii. p. 104, &c.

In a circle the horse is confined always to lead with his fore-leg, within the turn; otherwise he is said to *gallop false*. But here, too, the hind-leg of the same side must follow.

We say, *a hand-gallop*, *a Canterbury-gallop*, *a school-gallop*, &c. A smooth *gallop*, close to the ground, the French call the *Anglois gallop*, *gallop à l'Anglois*.

GALLOPER, in *Artillery*, is the name of a carriage which serves for a pound and a half gun. This carriage has shafts so as to be drawn without a SUMPTER, and is thought by some to be more convenient and preferable to other field carriages; and it may likewise serve for our light three and six pounders. See the dimensions and drawing of a *galloper* carriage in Muller's Treatise of Artillery, p. 186.

GALLOWAYS, is the name of a peculiar sort of horses, so called from the county of *Galloway* in Scotland, where they are bred. Tradition reports that this kind of horses sprung from some Spanish stallions, which swam on shore from some of the ships of the famous Spanish armada, wrecked on the coast, and coupling with the

mares of the country, furnished the kingdom with their poſterity. They were much eſteemed, and of a middling ſize, ſtrong, active, nervous, and hardy.

GALLOWS, an inſtrument of puniſhment, whereon perſons convicted capitally of felony, &c. are executed by hanging.

Among our anceſtors it was called *furca*, a *fork*: a name by which it is ſtill denominated abroad, particularly in France and Italy. In this latter country, the reaſon of the name ſtill ſubſiſts; the *gallows* being a real fork driven into the ground, across the legs whereof is laid a beam, to which the rope is tied.

GALLOWS *of a plough*, a name given by our farmers to a part of the common plough, from its reſembling a *gallows* made for the execution of malefactors in its form; being compoſed of three pieces of timber, one placed tranſverſely over the heads of the other two. The *gallows* are a part of the plough-head; they are fixed into the box of the plough, or that part through which the axis of the wheels paſſes. They make an angle with the box inclining upwards. The upper, or tranſverſe piece, is notched in ſeveral places, and ſerves to ſuſtain the WILDS, a pair of irons to which a ring and hooks are faſtened, and to theſe the chains of the harneſs, by which the whole plough is drawn along.

In ſome other parts of England, they call this whole part of the plough, the three pieces being iron inſtead of timber, by the name of the wilds; and the *gallows* of the PLOUGH is then the tranſverſe piece at the top of the CROWTYARES.

GALLS, or GALLNUTS. See GALL.

GALLUS. See COCK.

GALLUS *gruunens*, in *Ichthyology*, the name of an Eaſt Indian fiſh, approaching in the nature of the *ſurdus Adrianus*, and called by the Dutch *zeuse hurn*. Its body is thick, and rounded; its ſkin is free from ſcales, but is very uneven, full of tubercles, ſpotted, and variegated with ſhort ſtreaks of a blackiſh hue; its head is large and thick, and very full of tubercles; its noſe large, its eyes red, and its tail obtuſe; its belly-fins are red. It is a very well-taſted fiſh, and much valued there. When firſt taken out of the water, it makes a very remarkable grunting noiſe.

GALLUS *marinus*, in *Ichthyology*, a name given by many writers to the fiſh called in Engliſh the GURNET, and more commonly known in Latin by the name PAPER.

GALLUS *marinus* is alſo a name by which ſome have called the fiſh more frequently known by the name of the ORFE *piſcis*.

GALLY, on *ſhip-board*, a place in the cook-room, where the grates are put up, fires lighted, and the victuals boiled and roaſted.

GALLY-*worm*, in *Zoology*, an inſect known by moſt writers under the name *julus*. It is a land-inſect with a long body, compoſed of a great number of rings, and furniſhed with a great number of feet. It is found very frequently in gardens, and when touched, has the power of rolling itſelf up into a ball.

It is eſteemed a valuable medicine in the jaundice, and in ſuppreſſion of urine.

This animal is very common with us among rubbiſh, and is by ſome referred to the ſcolopendræ, but improperly; for though they agree in the great number of legs, ours is a harmleſs animal, and the ſcolopendræ are miſchievous creatures, armed with dangerous forceps. It is ſuppoſed by ſome, that this creature, common with us, would, on diſtillation, yield the ſame ſort of animal acid that is procured from the ant. The reaſon of the conjecture is, that the ant and this creature both agree in emitting a ſharp and pungent ſmell on being bruiſed; but theſe are not eaſily procured in plenty enough to make the experiment, as they are not a gregarious inſect like the ant. Poſſibly ſome more of the inſects may be found, on trial, to have the ſame acid. Phil. Trant. N° 68.

GAMBETTA, in *Ornithology*, the name of a bird ſomewhat reſembling the common redſhank. Its head, neck, and breaſt, are grey, full of brown ſpots; theſe are larger on the back, and ſmaller on the breaſt and belly, and ſmalleſt of all on the head. Its whole back is of a grey, a little inclining to a reddiſh brown on the lower part of the back, and on the wings; its belly is white, and its beak black. It is common in Italy, and ſome other places. Aldrovand. de Avib. lib. xx. and xxvi.

Mr. Pennant deſcribes one of this ſpecies, the *totanus gambetta* of Linnæus, which was ſhot on the coaſt of Lincolnſhire, about the ſize of the green-ſhank; the head, back, and breaſt, being of an aſh-brown, ſpotted with duſk yellow; the covers of the wings, ſcapulars, cinereous, edged with yellow; the primaries duſky; the ſhaft of the firſt feather white; belly white; tail duſky, bordered with yellow; and legs yellow. Zoology, vol. ii. p. 495.

GAMBEZON, GAMBESON, GAMBESO, in the *Ancient Military Language*, was a kind of coat or doublet, worn under the cuiraſs, to make it ſit eaſy, and prevent its hurting the body.

It was made of wool or cotton, quilted between two ſtuffs; and was likewiſe called *counter-point*.

Others deſcribe the *gambeſon* a kind of *ſort* quilted waiſtcoat, worn under the coat of mail, and hanging down over the thighs.

Pectora tot ferri, tot gambeſonibus ornat.

GAMBOGE is a concrete gummy reſinous juice of certain trees growing in Cambegia or Cambodia, and ſome other parts of the Eaſt Indies: it is brought over to us in large cakes or rolls, externally of a browniſh yellow, and internally of a deep reddiſh yellow, or orange colour, changing to a pale bright yellow on being manſioned. The gummy parts of this juice are ſo intimately blended with the reſinous, that the greateſt part of it is ſoluble either by water or ſpirit of wine: it is alſo inflammable, and eaſily melts with a very gentle heat. If mixed with an equal quantity of ſalt of tartar, it readily diſſolves in common water, in a few hours digeſtion; this ſolution, if kept over the fire, ſoon becomes a ſort of ſmooth glue or jelly; and this, by adding a large quantity of water, is eaſily reduced into a red clear liquor, in a warm digeſtion: this liquor, evaporated over a gentle fire, yields a greyiſh ſalt, which eaſily imbibes moiſture from the air, if not kept in a glaſs well ſtopped; and this extract purges in a ſmaller doſe than the gum itſelf, and yet with leſs irritation: its taſte, however, is extremely acrimonious and fiery, and it muſt therefore be well digeſted before it is given. There is, however, another method of giving it, yet more to be recommended than this for general uſe; this preparation is as follows: tie up the gum in a piece of linen cloth, and put it into a loaf juſt drawn from the oven; the loaf muſt be cut open for this purpoſe, and afterwards tied cloſe together, and ſet in ſome place where it will remain warm four and twenty hours, after this the gum is to be taken out and reduced to powder, and this powder tied up again, and put into another loaf, and ſo on to the fourth or fifth time; after which it is to be powdered and kept for uſe. By this eaſy preparation, this medicine loſes its violent operation, both as a purgative and emetic, and may be given with great ſafety; and the crumb of the firſt loaf, if eaten, proves purgative. Mem. Acad. Par. 1701.

In ſuch hydropic caſes as require the ſtricter cathartics, and in other diſorders accompanied with a redundance of ſerous humours, it is an uſeful and ſafe hydragogue; in hot, dry, bilious conſtitutions, it is never to be adminiſtered. In all caſes it is apt, on firſt uſing it, to vomit as well as purge. The doſe is from three or four grains to twelve, or at moſt fifteen. The emetic power of this medicine is reſtrained by joining it to mercurius dulcis. The pills of *gamboge* are prepared by mixing equal parts of *gamboge*, mercurius dulcis, aloes, and extract of black hellebore, with a fifteenth of their weight of eſſential oil of juniper-berries, and making the whole into a maſs with ſyrup of buck-thorn. Solutions of *gamboge* in alkalized water, and in diſtilled alkaline ſpirits, act only by ſtool and urine, and much more mildly than the juice in ſubſtance. The watery tincture is ſtill milder; but the ſpirituous tincture operates with extreme irritation both upwards and downwards. Lewis's Mat. Med.

Gamboge, diſſolved in water, forms a beautiful yellow pigment, and is much uſed as ſuch by painters. Dr. Lewis ſays, that it gives a beautiful and durable citron yellow ſtain to marble, whether rubbed in ſubſtance on the hot ſtone, or applied, as dragon's blood ſometimes is, in form of a ſpirituous tincture. When it is applied on cold marble, the ſtone is afterwards heated, to make the colour penetrate. Neumann's Chem. by Lewis, p. 920. note *w*.

GAME, *ludus*, a regular diverſion, or a ſport preſcribed and limited by rules.

Games may be diſtinguiſhed into thoſe of *exerciſe* and *addreſs*; and thoſe of *chance*, or *hazard*.

To the firſt belong *tennis*, *billiards*, *cheſs*, *bowls*, *cudgels*, *wreſtling*, *quoits*, *ſtoating with boats*, &c.

To theſe alſo belong the ancient *joſts* and *tournaments*.

Under the ſecond come *cards* and *dice*, &c.

Under cards, again, come ſeveral ſubordinate *games*; the principal whereof are OMBRE, PICQUET, BASSET, WHIST, &c.

GAMES, *ludi*, in the plural, were ſhews, or public repreſentations, uſed among the ancients on religious, funerary, and other ſolemn occaſions.

Such, among the Greeks, were the OLYMPIC, PYTHIAN, ISTHMIAN, and NEMEAN *games*.

Among the Romans, there were three ſorts of *games*; *ſacred*, *funerary*, and *judicrous*: and Auſonius obſerves a

difference,

difference, somewhat of the same kind, among those of the Greeks: two of their celebrated games being dedicated to gods, and two to heroes.

GAMES, *sacred*, were those instituted immediately in honour of some deity; of which kind there were the *ludi Cereales, Floralia, Martiales, Apollinares, Megalenses, Romani, Consuales* or *Circenses, Capitolini, Saeculares, Plebeii, Compitalitii, Augustales, Paludes*, and *Vestae*. See each described in its place.

To this class may also be referred those celebrated in memory of some illustrious person or action; so the *ludi Nemaeaus*, and *Actiaci*, &c.

Authors mention a decree of the Roman senate, by which it was enacted, that the public *games* should be consecrated, and inured with the worship of the gods, as a part thereof; and, accordingly, feasts, sacrifices, and *games*, appear to have made up the greatest part, or rather the whole, of the external worship or service offered to the deities of the Romans.

GAMES, *funeral*. See FUNERAL *games*.

GAMES, *hastiary, bull-baiting*, were those exhibited by private persons, out of their own purse, in order to gratify the people, or ingratiate themselves with them, or make way for their own preferment. Such were the combats of gladiators, scenic *games*, tragedies, comedies, and other theatrical and amphitheatrical sports.

GAMES, *Isthmian*, were of the same kind with the *games* of exercise and hazard among us. Such were the *ludus Trojanus*, or *Pyrrhicus*, the *tegere*, and *talis* or dice; and the *latrunculi*, or chess; the *discus*, or quoit; the *pila*, ball; *trochus*, top; *nuces*, or *par impar*, odd and even, with nuts; *harpastum*, foot-ball; *expita vel nervus*, cross and pile, &c.

Others distinguish the ancient *games* into three classes, viz. *vasti, venatici*, and *pedestres*. The first were called *equestrian*, or *curule games*, *ludi equestres*, or *curules*; being races of horses and chariots performed in the circus in honour of the Sun and Neptune.

The second were called *gymnici*, or *venatici*; being combats of men or beasts, in the amphitheatre, dedicated to Mars and Minerva.

The last, called *scenici, pedestri*, and *musici*, were tragedies, comedies, balls, &c. represented on the theatres, sacred to Venus, Bacchus, Apollo, and Minerva.

Homer gives us a fine description of the *games* which Achilles instituted at the funeral of his friend Patroclus, in his Iliad; and others of the different *games* held among the Phaeaces, Ithacans, and at the court of Alcinous, in his Odyssey. And Virgil's description of the *games* celebrated by Aeneas, at the funeral of old Anchises, is not inferior to any of them.

GAME is also used for all kinds of wild beasts and birds fit for eating, and which are sought after on that account.

Game includes not beasts of venery and chace; and also beasts and fowls of warren.

Some authors divide *game* into *terrae*, which include red and fallow deer; and *aquae*, to which belong hares, rabbits, pheasants and partridges.

A forest is a place set apart for preserving, feeding, breeding, &c. of all sorts of *game*, and consists of divers things, viz. soil, covert, laws, courts, judges, officers, *game*, and bounds.

A CHASE differs from a FOREST in this, among other things, that it has no variety of *game*.

Ways of catching *game* are by hunting, hawking, fowling, &c.

There is a great number of *laws made for the security and preservation of the game*. The restrictive laws relating to forests and *game* were introduced into Europe at the same time, and by the same people, as gave birth to the feudal system: on the irruption of the northern barbarians, it behoved every conquering general, when he settled the economy of a vanquished country, and partitioned it among his soldiers and feudatories, on condition of military service, to keep the *richest*, or natives of the country, who were not his military tenants, in as low a condition as possible, and especially to prohibit them the use of arms. In order to this, it became necessary to prohibit hunting and sporting, and that the conquerors should reserve this right to himself, and to such capital feudatories, or barons, to whom he should bestow it. This exclusive privilege well suited the martial genius of those conquering troops, who delighted in a sport which bore resemblance to war: and it is remarkable, that, in those nations where the feudal polity remains the most uncorrupted, the forest or *game* laws continue in their greatest vigour. In France all *game* is properly the king's; and in some parts of Germany it is death for a peasant to be found hunting in the woods of the nobility. In the times of the Britons our whole island was replenished with all sorts of *game*, which they all enjoyed in common: but when husbandry took place under the Saxon government, the beasts fled into desert tracts, called forests, which our royal ancestors reserved for their own diversion, on pain of a pecuniary forfeiture for such as interfered with their sovereign. But every free holder had the full liberty of sporting upon his own territories, provided that he abstained from the king's forests; as is expressed in the laws of Canute, and Edward the Confessor: *Sit quilibet liber & suus venationis suæ, in silvis & in agris, sibi propriis, & in domino suo, si absentiat animo habeat suum ingressum, ubicunque parem eu habere voluerit*. which indeed was the ancient law of the Scandinavian continent, from whence Canute probably derived it: *Cuique enim in propriis fundis quemlibet ferum quocunque modo venari permissum*. However, upon the Norman Conquest, the right of pursuing and taking all beasts of chase, and other animals called *game*, was held to belong to the king, and to such only as were authorized by him. This right was exerted at and after the time of the Norman establishment, with the utmost rigour. Blackst. Com. vol. iv. p. 411, &c. See FOREST.

The first qualification relating to the *game* was established by 13 Ric. II. stat. 1. cap. 13. which enacted that no layman, who hath not lands or tenements of 40*l.* a year, nor clergyman without preferment of 10*l.* a year, shall keep any greyhound or other dog for hunting, nor use ferrets, nets, and other engines for destroying *game*, on pain of a year's imprisonment.

By a statute in 33 Hen. VIII. cap. 6. it is enacted, that no person shoot with, or keep in his house, any cross-bow or stone-bow, hand-gun or hagbut, under the length of one yard, unless he have lands, tenements, annuities, or offices, of the yearly value of 100*l.* on pain of a forfeiture of 10*l.* for every offence: nor shall any person travel with a cross-bow bent, or gun charged, or shoot within a quarter of a mile of any town, except at a dead mark, or in defence of his house, under the like forfeiture, to be divided between the king and the prosecutor. This act continues still in force, though the object of it, which was the encouragement of the use of the long-bow, doth not now exist.

None under the degree of a baron, shall shoot with any hand-gun, within a city or town, or shoot at any fowl whatever with hail-shot, on the same forfeiture. 2 and 3 Edw. VI. cap. 14. This act was repealed by 6 and 7 Will. cap. 13.

Any person shooting in the night-time, or disguise, shall be deemed a felon, if he deny it if he confess, he is fineable at the next general sessions. 1 Hen. VII. cap. 7.

No person shall take any partridge or pheasant by nets &c. on the freehold of another person, without leave of the owner, under the penalty of 10*s.* half to him that sues, and half to the owner of the ground. 11 Hen. VII. cap. 17.

No person shall keep any net, called deer-lays or buck-stalls, on pain of 10*l.* a month. 19 Hen. VII. cap. 11.

None shall break into an inclosed park or inclosed ground, and chase out and kill any deer, under the penalty of 10*l.* to the party aggrieved, or treble damages and costs, and finding sureties for seven years. 5 Eliz. cap. 21. explained and amended by 3 Jac. cap. 13. and 7 Jac. cap. 13. If any person, of what estate or condition soever, shall take, kill, or destroy any pheasants or partridges in the night-time, and be convicted thereof at the assizes, sessions, or leet, he shall forfeit for every pheasant 40*s.* and for every partridge 20*s.* half to him that shall sue, and half to the lord of the manor. 23 Eliz. cap. 10.

None shall kill or take pheasants or partridges, with any net or engine, in the night-time, on forfeiture of 20*s.* for every pheasant, and 10*s.* for every partridge, 33 Eliz.

None shall hunt or hawk with spaniels in planting corn or before it be shocked, unless on his own ground, on the penalty of 40*s.* half to the king, and the other half to the proprietor of the ground.

He that is convicted of killing or taking a pheasant, partridge, duck, heron, hare, or other *game*; or of taking and destroying the eggs of swans, pheasants, or partridges; shall pay 20*l.* for every such fowl, hare, &c. to the use of the poor. 1 Jac. I. cap. 27.

Every person convicted to have kept a greyhound dog, or net, to kill or take deer, hare, pheasant, or partridge, unless he have inheritance in his own right, or the right of his wife, of 10*l.* per annum, a lease for life of 30*l.* per annum, or be worth 200*l.* in goods, or be the son of a knight or lord, or heir apparent of an esquire, shall pay 20*l.* for the use aforesaid, or be committed to goal for three months. This was the second qualification by estate or degree for killing *game*. Nor shall any sell, or buy to sell again, any deer, hare, pheasant or partridge in pain of 40*s.* for every deer, 10*s.* for every hare and partridge, and 20*s.* for every pheasant, half to him that will sue, and half to the poor. Id. stat. cap. 27.

The

The next qualification relates to deer and conies only: this forbids a person, not having hereditaments of 100l. a year, or goods of 200l. value, from using any gun or bow to kill deer or conies, or from keeping nets or every dogs, except he hath included grounds, in which the inclosure of the copies amounts to 100l. a year, or be a keeper or warrener, under the penalty of having his guns, nets, &c. liable to be taken away by any person having lands or hereditaments of 100l. a year in fee or for life. 3 Jac. I. cap. 13.

The lord of a manor, or one having inheritance of 40l. per annum, lives estate of 80l. or goods worth 400l. or their servants licensed by them, may take pheasants or partridges within their own lands or precincts, in the day-time, between Michaelmas and Christmas. 7 Jac. I. cap. 11.

Hawking of pheasants and partridges between the first of July and the last of August is prohibited, under the penalty of 20s. for every such hawking, and 20s. for every pheasant or partridge destroyed. 7 Jac. cap. 11.

If any that kill or take away any red or fallow deer, without consent of the owner, shall forfeit 20l. to be taken by distress; one half to the owner, and the other to the informer; or, for want of such distress, shall suffer a year's imprisonment. 19 Car. II.

Lords of manors, or other qualified, not under the degree of esquire, may commission one or more gamekeepers, who may cause all guns, dogs, bows, &c. of persons not having estates, in their own or wife's right of 100l. per annum freehold, or for term of life; or 150l. per annum leasehold, for ninety-nine years or upwards; or not being sons and heirs of esquires, or of higher degree; or owners or keepers of a forest, park, chase, or warren; and destroy, or convert such guns, &c. to the use of the lord. 22 and 23 Car. II. cap. 25. For this purpose it has been judged necessary to have a warrant from a justice of peace, after information and oath of the offence first made. This is the last general qualification for killing game, and that which is now most to be regarded.

If any enter a coney-warren, though not included, and chase or kill conies, he shall forfeit treble damages, and be imprisoned three months: and they that kill conies in the night time upon the borders of warrens, or grounds used for keeping conies, shall be answered at the discretion of the justice of peace, in any sum not exceeding 10l. Id. stat.

He who unlawfully hunts, takes in toils, kills, or takes away any deer, in any forest, chase, park, purlieu, or other inclosed ground, or shall be aiding and abetting therein shall forfeit 20l. for unlawfully coursing or hunting, though none shall be wounded or taken; and in case any be wounded, or killed, or taken, not for carrying such deer, one third to the poor, one third to the informer, and one third to the owners of the deer, to be levied by distress. 3 Will. and Mary. 5 Geo. I. cap. 15. 9 Geo. cap. 22. and 10 Geo. II. cap. 32. And if a keeper of a forest, &c. be an offender herein, or be aiding thereto, he shall forfeit 40l. 5 Geo. I. to be levied as above.

In case any hares, partridges, pheasants, fish, fowl, or other game shall be found in any offender's house, he shall forfeit 40s. (um not less than 5l. nor more than 20l. to be levied by distress, half to the informer, and half to the poor; or, in want thereof, he shall be committed to the house of correction for a space of time not exceeding three months, nor less than ten days. And if any person, not qualified by law, shall keep or use any bows, greyhounds, setting-dogs, ferrets, tumblers, nets, &c. he shall be subject to the same penalties. 4 and 5 Will. cap. 23.

If any bigler, chapman, carrier, inn-keeper, or victualler shall have in his keeping any hare, pheasant, partridge, heath game, or grouse, not put in his hands by a person qualified by law, he shall forfeit 5l. for every such hare, 20s. half to the informer, and half to the poor, to be levied by distress; or, for want thereof, he shall be sent to the house of correction for three months for the first offence, and for every other offence four months. 5 Anne, cap. 14.

If any person, whether he be qualified or not, shall sell, or expose to sale any hare, pheasant, partridge, moor, heath game, or grouse, he shall be liable to the same penalty. 28 Geo. II. cap. 12.

Persons not qualified, keeping greyhounds, lurchers, setting-dogs, or engines to destroy game; and gamekeepers, who, under colour of office, kill and sell game without their master's knowledge; are liable to the like penalty. 5 Anne, cap. 14.

No lord of a manor is to appoint more than one gamekeeper, and his name to be entered with the clerk of the peace, who is to give a certificate thereof; otherwise he is liable to the penalties against biglers. And if any other game keeper, whose name is not so entered, who shall not be otherwise qualified by the laws of this kingdom to kill game, shall kill, sell, or expose to sale any hare, pheasant, partridge, moor, heath game, or grouse, he shall, on conviction before one justice, and on the oath of one witness, be liable to the same penalty for the first offence, and for every other offence be sent to the house of correction for four months. 5 and 6 Anne, cap. 23.

If any hare, pheasant, &c. be found in the possession of a person not qualified, such shall not be entitled to it by any person that is qualified, the same shall be adjudged an exposing it to sale. Persons delivering a hare in the night, shall incur the forfeiture of 5l. 9 Anne, cap. 25. 28 Geo. II. cap. 12.

Any justice of the peace, and lord within his manor, may take away such hare, &c. found in the custody of a person not qualified; and any person that shall destroy, sell, or have any hare, &c. and shall in three months discover any bigler, carrier, victualler, &c. that hath bought or sold, or offered to buy or sell, or had in their possession any hare, &c. shall be discharged of the penalty annexed to his own offence, and receive the same benefit as any other informer. 5 Anne, cap. 14.

No lord of a manor shall appoint a gamekeeper, with power to kill or destroy game, unless he be qualified by the laws of the realm, be under a servant of such lord, or be immediately employed to kill game for the sole use of such lord; nor shall any lord authorize a person not qualified to keep or use guns, greyhounds, &c. and such persons as shall be found offending in either of these points, shall, for every offence, forfeit 5l. 5 Geo. I. cap. 14. Every person not in a park, paddock, or other inclosed ground, where deer are usually kept, and actually found or seen any sort of fallow deer, he shall be transported to the plantations for seven years. 5 Geo. I. Sess. II. Act 22.

If any person shall by hays, runnels, or other nets, drive and take any wild ducks, teal, widgeons, or any other water-fowl, in any place of resort for wild-fowl in the marshes below, between June 1 and Oct. 1, yearly, he shall, on conviction, forfeit for every such fowl 5s. half to the informer, and half to the poor, by distress, or be committed to the house of correction for a time not exceeding one month, not less than fourteen days; and the nets shall be seized and destroyed by the gentlemen of the justice. 9 Anne, cap. 25. 10 Geo. II. cap. 32. And persons destroying the eggs of any mallard, teal, or other water-fowl, from March 21 to June 1, shall be liable to a year's imprisonment, or forfeiture of one penny for every egg. 24 Hen. VIII. cap. 11.

No person shall, on any pretence whatsoever, take, kill, carry, sell, buy, or have in his possession or use, any partridge, between Feb. 12 and Sept. 1; or any pheasant, between Feb. 1 and Oct. 1, yearly; on pain of forfeiting, on conviction by one witness in any of the courts of record at Westminster, 5l. for every such fowl, with full costs. 5 Geo. II. cap. 19.

And if any person shall shoot at, kill, or take any dove-house or pigeon, and be convicted by confession, or oath of one witness, before one justice, where the offence was committed, or the party apprehended, he shall forfeit 20s. to the prosecutor, or be committed to gaol to the house of correction for a time not exceeding three calendar months, nor less than one. Id. stat.

If any person shall knowingly or wilfully kill, take or destroy, or use any gun, dog, ferret, net, or other engine, with intent to kill, take, or destroy any hare, pheasant, partridge, moor game, or heath game, in the night between the hours of seven at night and six in the morning, from the 12th day of October to the 12th day of February, and between the hours of nine at night and four in the morning, from the 12th day of February to the 12th day of October; or, in the day-time, upon a Sunday or Christmas-day; he shall, on conviction by oath of one witness, before one justice, forfeit for the first offence a sum not exceeding 20l. nor less than 10l. for the second offence not more than 30l. nor less than 20l. and for the third and every subsequent offence 50l. such penalty to be levied by distress, and to be paid half to the informer, and half to the poor. In case of refusal of payment of the fine of 50l. the offender shall be committed to the house of correction for no less than 6s. nor more than twelve calendar months, unless such penalty shall be sooner paid; and the offender may be once publicly whipped, if the justices think proper. 13 Geo. III. cap. 80.

No person shall take, destroy, carry, sell, buy, or have in his possession any heath fowl, called black game, between Dec. 10 and Aug. 20; nor any grouse, commonly called red game, between Dec. 10 and Aug. 12; nor any bustard, between March 1 and Sept. 1, in any year, on

pain

pain of forfeiting for the firſt offence any ſum not exceeding 10l. nor leſs than 10s. and for the ſecond, and every ſubſequent offence, not exceeding 30l. nor leſs than 20s. half to the informer, and half to the poor. 13 Geo. III. cap. 55. See FISHING, HAWKING, HORSES, SWANS, &c.

GAME, *Back.* See GROUSE.

GAMENAS. See GOMENAS.

GAME, *Red.* See GOMENAS.

GAME, *Moor.* See PTARMIGAN.

GAME-*keeper*, is one who has the care of keeping and preſerving the game, being appointed thereto by the lord of a manor. See GAME, *ſupra*.

GAMELIA, Γαμήλια, a nuptial feaſt, or rather ſacrifice, held in the ancient Greek families on the day before a marriage.

It was thus called from γαμος, marriage; whence alſo Γαμηλιος, an epithet, or ſurname, given to Jupiter and Juno, conſidered as preſiding over marriages.

GAMELION, Γαμηλιων, in *ancient Chronology*, the eighth month of the Athenian year. It contained twenty-nine days, and anſwered to the latter part of our January, and the beginning of February.

This month had its name from being ſacred to Jupiter and Juno, diſtinguiſhed by the epithet Γαμηλιος, becauſe they preſided over marriages.

GAMELION, or GAMELIUM, a poem, or compoſition, in verſe, on the ſubject of a marriage; more uſually called an EPITHALAMIUM.

GAMETRIA. See GEMETRIA.

GAMING, the art or act of performing, or practiſing a game, particularly a game of hazard.

All public *gaming* is ſeverely prohibited; and what money is thus loſt, is recoverable again by law.

In China, *gaming* is equally prohibited the common people; and the mandarins; and yet this does not hinder their playing, and frequently loſing all they have; their lands, houſes, children, and even wives, which are ſometimes laid on a ſingle card. Le Compte.

By 16 Car. II. cap. 7. if any perſon by playing or betting ſhall loſe more than 100l. at one time, he ſhall not be compellable to pay the ſame; and the winner ſhall forfeit treble the value, one moiety to the king, and the other moiety to him that ſhall ſue for it, with treble coſts. By 9 Anne, cap. 14. all notes, bills, bonds, judgments, mortgages, or other ſecurities, given for money won by playing at cards, dice, tables, tennis, bowls, or other games, or by betting on the ſides of ſuch as play at any of thoſe games, or for repayment of any money knowingly lent for ſuch gaming or betting, ſhall be void: and where lands are granted by ſuch mortgages or ſecurities, they ſhall go to the next perſon who ought to have the ſame, as if the grantee were actually dead, and the grant had been made to the perſon ſo inſiſted, after the death of the perſon ſo incumbering the ſame. If any perſon playing at cards, dice, or other game, or betting, ſhall loſe the value of 10l. at one time, to one or more perſons, and ſhall pay the money, he may recover the money loſt, by action of debt within three months afterward; and if the loſer does not ſue, any other perſon may do it and recover the ſame, and treble the value with coſts, one moiety to the proſecutor; and the other to the poor; and the perſon proſecuted ſhall anſwer upon oath, on preferring a bill to diſcover what ſums he hath won.

Perſons by fraud or ill practice, in playing at cards, dice, or by betting a ſhare in the ſtakes, &c. or by betting, winning any ſum above 10l. ſhall forfeit five times the value of the thing won, and ſuffer ſuch infamy and corporal puniſhment as in caſes of wilful perjury, being convicted thereof on indictment or information; and the penalty ſhall be recovered by action, by ſuch perſon as will ſue for the ſame: and if any perſon ſhall aſſault and beat, or challenge to fight any other perſon, on account of money won by *gaming*, upon conviction thereof he ſhall forfeit all his goods, and ſuffer impriſonment for two years. Stat. 9 Anne. Alſo by this ſtatute, any two or more juſtices of the peace may cauſe ſuch perſons to be brought before them as they ſuſpect to have no viſible eſtates, &c. to maintain them; and if they do not make it appear, that the principal part of their expences is got by other means than *gaming*, the juſtices ſhall require ſecurities for their good behaviour for a twelvemonth, and in default of ſuch ſecurity commit them to priſon until they find it: and playing or betting during the time, to the value of 10l. ſhall be deemed a breach of behaviour, and a forfeiture of their recognizances. Ibid.

This ſtatute of Anne is further enforced by ſtat. 18 Geo. II. cap. 34. and ſome deficiencies are ſupplied; the forfeitures of that act may be now recovered in a court of equity; and, moreover, if any man be convicted, upon information or indictment, of winning or loſing at any ſitting 10l. or 20l. within twenty-four hours, he ſhall forfeit five times the ſum won, deducting the charges ſhall go to the poor. By ſeveral ſtatutes of the reign of king George II. viz. 13 Geo. II. cap. 28. 13 Geo. II. cap. 19. and 18 Geo. II. cap. 34. all private lotteries by tickets, cards, or dice, and particularly the games of faro, hazard, ace of hearts, hazards paſſage, rag paſs, and all other games with dice, except back-gammon, are prohibited under a penalty of 200l. for him that ſhall erect ſuch lotteries, &c. and 50l. a time for the players. Public lotteries, unleſs by authority of parliament, and all arrangements of the ſame nature, under the denomination of ſales or otherwiſe, which in the end are equivalent to lotteries, were before prohibited by a great variety of ſtatutes, under heavy pecuniary penalties. 10 and 11 Will. III. cap. 17. 9 Anne, cap. 6. § 56. 10 Anne, cap. 26. § 109. 8 Geo. I. cap. 2. § 30. 37. 9 Geo. I. cap. 19. § 4. 5. 6 Geo. II. cap. 35. § 29. 30.

Gaming houſes are prohibited under ſevere penalties by ſeveral ſtatutes. No perſon ſhall, for his gain or living, keep any common houſe or place of bowling, coyting, cloyth, caſts, ſkittle-bowl, tennis, dicing-table, carding, or any unlawful game, on pain of 40l. a day: and every perſon frequenting ſuch houſes and play, and there playing, ſhall forfeit 10l. 2d. And juſtices of the peace, and the head officers of corporations, have power to enter places ſuſpected of unlawful *gaming*, and to arreſt and impriſon the keepers and players, till they give ſecurity to keep and reſort to ſuch houſes no longer: and ſuch officers are bound to make ſearch for ſuſpected houſes, weekly or monthly, under a forfeiture of 40l. a month. Father, miniſters, labourers, ſervants, &c. are prohibited to play at tables, dice, tennis, cards, bowls, &c. out of Chriſtmas, on pain of 20s. and in Chriſtmas only in the houſes or preſence of their maſters. 33 Hen. VIII. cap. 9. Moreover, *gaming* in public-houſes is prohibited under a penalty to the keepers of the houſe, who knowingly ſuffers it, of 40s. for the firſt offence, and for every other offence 20l. by diſtreſs, three fourths of which ſhall be to the poor, and one fourth to the informer. And any journeyman, labourer, apprentice, or ſervant, who ſhall game in ſuch a houſe, ſhall forfeit on conviction by confeſſion, or the oath of one witneſs not more than 20s. nor leſs than 5s. at the pleaſure of the juſtice, or be committed to hard labour for a term not exceeding a month. 30 Geo. II. cap. 24. And by 25 Geo. II. cap. 36. any houſe, or place kept for public dancing, muſic, or other entertainment, in London, or within twenty miles, (except places authorized by letters patent, or licence of the crown, or lord chamberlain,) without licence, granted at the preceding Michaelmas ſeſſions, and ſigned and ſealed by four juſtices in open court, and of which notice is given over the door or entrance of ſuch licenſed place in the following words, viz. Licenſed purſuant to act of parliament of the 25th of king George the Second; ſhall be deemed a diſorderly houſe or place, and the keeper thereof ſhall forfeit 300l. with full coſts. A conſtable, on notice given him in writing by any two inhabitants of the parith paying 5ſol and 10ſ. of any perſon keeping ſuch diſorderly houſe, and on their making oath to ſuch notice, and entering into a recognizance of 120l. each to produce evidence of the offence, ſhall enter into a recognizance of 30l. before a juſtice of the peace, to proſecute ſuch perſon; and the juſtice ſhall iſſue his warrant for bringing the accuſed perſon before him, and bind him over to appear at the next ſeſſions or aſſizes: if the conſtable neglect or refuſe to comply with ſuch notice, &c. he ſhall forfeit 20l. to each of the ſaid inhabitants; and the conſtable ſhall be allowed the reaſonable expences of the proſecution, to be paid by the overſeers of the poor, and on conviction of the offender, the overſeers ſhall pay 10l. to each of ſuch inhabitants.

The buſineſs of chance or hazard, on which the laws of *gaming* depend, is of mathematical conſideration; inaſmuch as it admits of more, and leſs. It is, or is ſuppoſed to be, an equality of chance, upon which the gameſters ſet out: this equality is to be broken in upon in the courſe of the game by the greater good fortune or addreſs of one of the parties, upon which he comes to have a better chance; ſo that his ſhare in the depoſit, or ſtaked, is now proportionably more or better than at firſt: this more and leſs is continually varying, and runs through all the ratios between equality and infinite difference; or from an infinitely little difference till it arrives at an infinitely great one: upon which the game is ended. The whole game, therefore, with reſpect to the event or iſſue thereof, is only a change of the quantity of each perſon's ſtake, or chance, or of the proportion their two ſhares bear to each other; which mathematics alone can meaſure.

Hence ſeveral authors have conſidered the variety of chance in ſeveral caſes and circumſtances that occur in

ranking; particularly M. de Moivre, in a treatise entitled the Doctrine of Chances, the best edition being published in 1756; of which we shall here give the reader an abstract.

Laws of chance applied to GAMING. If the reader, who is not well conversant with subjects of this nature, consider the articles EXPECTATION and PROBABILITY, he will be at no loss to understand the solution of the following cases; which, as they are the more simple and easy, will lead to the illustration of more complex and intricate calculations.

1. *To find the probability of throwing an ace in the throw of one die.* The first part of the probability required is that of throwing an ace at the first throw, which is $\frac{1}{6}$; but as the probability of nulling it in this throw is $\frac{5}{6}$, and that of throwing it in the second is $\frac{1}{6}$, the second part of the probability required, being the product of both these, will be $\frac{5}{6} \times \frac{1}{6} = \frac{5}{36}$; and therefore the whole probability is $\frac{1}{6} + \frac{5}{36} = \frac{11}{36}$.

2. *To find the probability of throwing an ace in three throws.* The probability of throwing it in the first throw is $\frac{1}{6}$; and the probability of nulling it is $\frac{5}{6}$, which, being multiplied by $\frac{11}{36}$, the probability of throwing it in the two remaining times by case 1, will give $\frac{5}{6} \times \frac{11}{36} = \frac{55}{216}$ for the second part of the probability required; and, therefore, the whole probability will be $\frac{1}{6} + \frac{55}{216} = \frac{91}{216}$.

3. *To find the probability of throwing an ace in four throws.* This is evidently, by the preceding cases, $\frac{1}{6} + \frac{5}{6} \times \frac{91}{216} = \frac{455}{1296} = \frac{671}{1296}$; and the probability of the contrary is $\frac{625}{1296}$, because $\frac{671}{1296} + \frac{625}{1296} = \frac{1296}{1296} = 1$, which denotes certainty.

4. *To find the probability of throwing two aces in two throws.* The probability required is $\frac{1}{6} \times \frac{1}{6} = \frac{1}{36}$, the events in this case being independent. See EXPECTATION.

5. *To find the probability of throwing two aces in three throws.* The probability of throwing an ace in the first throw is $\frac{1}{6}$, and the probability of throwing it once in the two remaining throws is $\frac{11}{36}$, by case 1: consequently the last part of the probability required is $\frac{1}{6} \times \frac{11}{36} = \frac{11}{216}$. But if the ace be missed the first time, the probability of which is $\frac{5}{6}$, there remains the probability of throwing it twice together, which is $= \frac{1}{36}$ by case 4: therefore the probability of both events is $\frac{5}{6} \times \frac{1}{36} = \frac{5}{216}$; and the whole probability required is $\frac{11}{216} + \frac{5}{216} = \frac{16}{216}$.

6. *To find the probability of throwing two aces in four throws.* The probability of throwing an ace the first time is $\frac{1}{6}$, and the probability of throwing it in three times is $\frac{91}{216}$ by case 2: and the probability of both happening is $\frac{1}{6} \times \frac{91}{216} = \frac{91}{1296}$, the first part of the probability required. But the probability of nulling the ace for the first time is $\frac{5}{6}$, and the remaining probability of throwing it twice in three throws is $\frac{16}{216}$ by case 5: therefore the probability of both together is $\frac{5}{6} \times \frac{16}{216} = \frac{80}{1296}$, the second part of the probability required: and, therefore, the whole probability is $= \frac{91}{1296} + \frac{80}{1296} = \frac{171}{1296}$.

In the same manner we may find the probability of throwing an ace as often as shall be demanded in any given number of throws.

From these familiar and more restricted cases, we may deduce a more general and comprehensive theorem. Let a be the number of chances for the happening of an event, and b the number of chances for its failing; then the probability of its happening *once* in any number of trials will be expressed by the series $\frac{a}{a+b} + \frac{ab}{(a+b)^2} + \frac{ab^2}{(a+b)^3} + \frac{ab^3}{(a+b)^4}$, &c. continued till the number of terms be equal to the number of trials given: e. gr. let $a = 1$, $b = 5$, and the number of trials given $= 3$; the probability required will be expressed by $\frac{1}{6} + \frac{5}{36} + \frac{25}{216} = \frac{91}{216}$.

Again, the probability of the event's happening *twice* in any given number of trials will be expressed by the series $\frac{2ab}{(a+b)^2} + \frac{3ab^2}{(a+b)^3} + \frac{4ab^3}{(a+b)^4} + \frac{5ab^4}{(a+b)^5}$, &c. continued till the number of terms, wanting one, be equal to the number of trials given: e. gr. let $a = 1$, $b = 5$, and the number of trials $= 4$; the probability required will be $\frac{10}{216} + \frac{75}{1296} + \frac{500}{7776} + \frac{3125}{46656} = \frac{671}{1296}$. And the probability of the event's happening *thrice* in any given number of trials will be expressed by the series $\frac{a^3}{(a+b)^3} + \frac{3a^3b}{(a+b)^4} + \frac{6a^3b^2}{(a+b)^5} + \frac{10a^3b^3}{(a+b)^6}$, &c. continued till the number of terms, wanting two, be equal to the number of terms given. These particular series may be expressed under a general one in the following manner: let a and b be as before, and their sum $= a + b = s$; the number of times which the event is required to happen to any given number of trials represented by n; then the probability of the event's happening t times in n trials will be expressed by the series $\frac{a^t}{s^t} \times 1 + \frac{t \cdot n - t + 1}{1} \cdot \frac{b}{s} + \frac{t \cdot n - t + 1 \cdot t + 1}{1 \cdot 2} \cdot \frac{b^2}{s^2} + \frac{t \cdot n - t + 1 \cdot t + 1 \cdot t + 2}{1 \cdot 2 \cdot 3} \cdot \frac{b^3}{s^3}$, &c. continued to as many terms, exclusive of the common multiplicator $\frac{a^t}{s^t}$, as are denoted by the number $n - t + 1$. On the other hand, the probability of the event's not happening so often as t times, making $n - t + 1 = r$, will be expressed by the series $1 + \frac{br}{s} + \frac{br \cdot r+1}{1 \cdot 2} \cdot \frac{b^2}{s^2} + \frac{br \cdot r+1 \cdot r+2}{1 \cdot 2 \cdot 3} \cdot \frac{b^3}{s^3}$, &c. continued to as many terms, exclusive of the common multiplicator, as are denoted by the number t. By means of these two problematics it always is equal to unity; therefore, the first series may be used when t is less than $\frac{n+1}{2}$; and the second when t is less than $n - t + 1$: in other words, the first or second may be used when t is less or greater than $\frac{n+1}{2}$. E. gr. let a be $= 1$, $b = 35$, $s = 24$, and $n = 1$: in this case twenty-four terms of the first series would be necessary to answer the question, but one term of the second will be sufficient; and the probability of an event's not happening once in twenty-four trials, which has one chance to happen, and thirty-five to fail, will be expressed by $\frac{35^{24}}{24^{24}} \times 1$: this quantity by the help of logarithms, will be found nearly equal to the decimal 0.50871, which, subtracted from unity, leaves a remainder 0.49129, expressing the probability required: and, therefore, the odds against the happening of the event will be fifty to forty-nine nearly. Again, if $a = 1$, $n = 60$, and $n - t + 1 = 59$, in this case fifty-nine terms of the first series will be necessary, and only two of the second; and, therefore, by the second series, the probability of an event's not happening *once* in sixty trials will be $\frac{35^{59}}{36^{59}} \times 1 + \frac{59}{36} = 0.5007$, which, subtracted from 1, leaves the remainder 0.4993, expressing the probability required; consequently, the odds against the event happening *once* in sixty times will be little more than 500 to 499.

To find the probability of throwing one ace, and no more, in four throws. From the unlimited probability of the ace's being thrown in four throws, subtract the probability of its being thrown twice in that number of throws; i. e. from $\frac{671}{1296}$ by case 3, subtract $\frac{171}{1296}$ by case 6, and the remainder $\frac{500}{1296}$ gives the probability required: and $\frac{796}{1296}$ the probability of the contrary; and

the odds against throwing one ace, *and no more*, in four throws, are 796 to 500, or 8 to 5 nearly.

8. *If* A *and* B *play together, and* A *wants two game of being up, and* B *wants two, what are their respective probabilities of winning the set?* It is plain that A wants only to win once in two games, and B wants to win twice together: and if both have an equal chance, the probability which B has of winning the firſt game will be $\frac{1}{2}$, and the probability of his winning twice together will be $\frac{1}{2}\times\frac{1}{2}=\frac{1}{4}$; and therefore the probability which A has of winning once in two games will be $1-\frac{1}{4}=\frac{3}{4}$; conſequently the odds of A's winning are three to one.

9. *If* A *and* B *play together, and* A *wants one game, and* B *wants two of being up; but the chances whereby* B *may win a game are double to thoſe of* A, *to find the reſpective probabilities of winning.* In this caſe, the probability which B has of winning a game is $\frac{2}{3}$, and the probability of his winning twice together is $\frac{2}{3}\times\frac{2}{3}=\frac{4}{9}$; and, therefore, the probability of A's winning the ſet is $1-\frac{4}{9}=\frac{5}{9}$; and the odds of A's winning one before B wins twice, which the queſtion requires, are as five to four.

In general, whatever be the number of games which A and B reſpectively want of being up, the ſet will be concluded at the moſt in ſo many games, wanting one, as is the ſum of the games wanted between them. For, if A wants three games, and B wants five of being up, the greateſt number of games which A can win of B, before the determination of the play, will be two, and the greateſt number which B can win of A will be four, and the whole number for a but, ſuppoſing they have played ſix games, the next game will terminate the play; and, therefore, the utmoſt number of games that can be played between them will be $5+3-1=7$.

10. *If* A *wants three games, and* B *wants ſeven of being up, and their reſpective chances of winning a game are as three to two; to find the reſpective probabilities of winning the ſet.* The ſum of the games is ten, and the ſet will be concluded in nine games, and, therefore, A undertakes to win three out of nine games, and B to win ſeven; then, by the ſecond caſe of the preceding theorem, n being $=9$, $l=3$, $c=2$, $s=5$, and $n-l+1$, or $p=7$, the probability which B has of winning the ſet will be expreſſed by $\frac{5}{6^9}\times 1+\frac{21}{6^8}+\frac{252}{6^7}=\frac{5}{64}\times 484=0.28172$ nearly, which, ſubtracted from unity, leaves a remainder $=0.71828$, expreſſing the probability which A has of winning; conſequently the odds of A's winning the ſet will be 71828 to 28172, or nearly 18 to 7.

Mr. de Moivre has alſo illuſtrated the principles of gaming, applied in the preceding caſes, in a different and more general way, by ſuppoſing two dice, having the ſame or a different number of equal faces; it is obvious that the number of all the variations which the two dice can undergo will be obtained by multiplying the number of faces of the one by the number of faces of the other. From hence it follows, that, if the faces of each die are diſtinguiſhed into white and black, and the number of white faces on the firſt is a, and that of the black faces b, and alſo the number of white and black faces on the ſecond α and β reſpectively, the product of $A+B$ multiplied by $\alpha+\beta$, i. e. $A\alpha+A\beta+B\alpha+B\beta$ will exhibit all the variations of the two dice: $A\alpha$ will repreſent the number of all the chances whereby the two dice may exhibit two white faces; $A\beta$ the number of all the chances whereby a white face of the firſt may be joined with a black face of the ſecond; $B\alpha$ the number of all the chances whereby a white face of the ſecond may be joined with a black face of the firſt; and $B\beta$ the number of all the chances whereby a black face of the firſt may be joined with a black face of the ſecond. Moreover, as theſe ſeveral quantities may be connected together ſeveral ways, the ſum of two or more of any of them will anſwer ſome queſtion of chance: e. gr. the number of chances for throwing a white face with the two dice above mentioned, will be repreſented by the three parts $A\alpha+A\beta+B\alpha$, becauſe every one of theſe comprehends a caſe wherein a white face is concerned: but if the queſtion were reſtricted by a previous ſuppoſition, that, if a perſon throw two white faces together, the wager would be loſt, the two terms $A\beta+B\alpha$ would repreſent all his chances. Further, if a third die be added, whoſe white faces are ϵ, and black faces ϕ, the preceding product, viz. $A\alpha+A\beta+B\alpha+B\beta$, multiplied by the whole number of faces of the third die, viz. $\epsilon+\phi$, or $A\alpha\epsilon+A\beta\epsilon+B\alpha\epsilon+B\beta\epsilon+A\alpha\phi+A\beta\phi+B\alpha\phi+B\beta\phi$, will exhibit the number of all the variations which the three dice can undergo: in this caſe $A\alpha\epsilon$ repreſents the number of chances for throwing three white faces, $A\beta\epsilon$ the number of chances whereby both the firſt and third die may exhibit a white face, and the ſecond a black one, &c. and by joining two or more of theſe terms, ſome queſtion of chance will be anſwered: e. gr. the number of chances for throwing two white faces and a black one will be repreſented by $A\beta\epsilon+B\alpha\epsilon+A\alpha\phi$, and the odds in favour of him who undertakes to throw them will be $A\beta\epsilon+B\alpha\epsilon+A\alpha\phi$ to $A\alpha\epsilon+B\beta\epsilon+A\beta\phi+B\alpha\phi+B\beta\phi$; and the probability of the event will be expreſſed by a fraction, whoſe numerator is the number of chances required, and the denominator the whole number of variations which all the dice can undergo. E. gr. the probability of throwing three white faces with the three dice above mentioned will be expreſſed by

$$\frac{A\alpha\epsilon}{A\alpha\epsilon+A\beta\epsilon+B\alpha\epsilon+A\alpha\phi+B\beta\epsilon+A\beta\phi+B\alpha\phi+B\beta\phi},$$

or, ſeparating the factors in the denominator,

$$\frac{A\alpha\epsilon}{A+B}\times\frac{\epsilon}{\alpha+\beta}\times\frac{\alpha}{A+B}\times\frac{\alpha}{\alpha+\beta}$$

ſo that the probability of the happening of ſeveral events independent is the product of all the particular probabilities whereby each particular event may be produced. See EXPECTATION.

In the preceding caſe of two dice, if A be $=a$, and $B=b$, $A\alpha+A\beta+B\alpha+B\beta$ will become $=a\alpha+a\beta+b\alpha+b\beta$; and $a\alpha=A\beta+B\alpha$ will expreſs the number of variations, whereby with two dice of the ſame reſpective number of white and black faces, a white face and a black one may be thrown. And in the caſe of three dice, $A\beta\epsilon+B\alpha\epsilon+A\alpha\phi$ will become $=3a^2b$, or, one term of the binomial $a+b$, raiſed to the cube, will expreſs the number of variations, whereby three dice of the ſame kind would exhibit two white faces and a black one.

11. From the above reaſoning the following general rule may be deduced; viz. in a number of dice $=n$, each of which is diſtinguiſhed into white and black faces, repreſented reſpectively by a and b, if $a+b$ be raiſed to the power n, the firſt term of that power will expreſs the number of chances whereby n white faces may be thrown; the ſecond term will expreſs the number of chances whereby $n-1$ white faces and 1 black face may be thrown; the third term will expreſs the number of chances whereby $n-2$ white faces and 2 black faces may be thrown, &c. and the reſpective numbers of white and black faces are repreſented by the indices of a and b in any given term.

To find the probability of throwing an ace in four throws with a common die of ſix faces. Since the throwing of one die four times ſucceſſively is the ſame thing as throwing four dice at once, the chance of throwing an ace is the ſame in the one caſe as in the other. Let the ace, then, in each of the four dice, anſwer to one white face, and the reſt of the points to five black faces, or a be $=1$, and $b=5$; raiſe $a+b$ to its fourth power, and every one of the terms in $a^4+4a^3b+6a^2b^2+4ab^3+b^4$, that has a, will be a part of the number of chances whereby an ace may be thrown: conſequently $a^4+4a^3b+6a^2b^2+4ab^3$, i. e. $1+20+150+500=671$, will expreſs the number of chances whereby an ace may be thrown with four dice, or in four ſucceſſive throws of a ſingle die; but the number of all the chances in the fourth power of $a+b$ or $b=1296$; and, therefore, the probability required is meaſured by the fraction $\frac{671}{1296}$. See caſe 3. It is evident that b, or the laſt term of the above power, expreſſes the number of chances whereby the ace may fail in every one of the dice; and the probability of that failing is $\frac{b}{a+b}=\frac{625}{1296}$; and, therefore, the probability of not failing, or of throwing an ace in four throws is $1-\frac{625}{1296}=\frac{671}{1296}$, as before. When the number of dice is n, b^n, the laſt term of the power $a+b^n$, will always repreſent the number of chances whereby the ace may fail in n times; and, therefore, $\frac{b^n}{a+b^n}$ is the probability of its failing; and the probability of throwing an ace, in a number of throws expreſſed by n, will be $1-\frac{b^n}{a+b^n}=\frac{a^n+a^{n-1}b+\&c.}{a+b^n}$.

To find the probability of throwing with two ſingle dice two aces in four throws, or of throwing at one throw two aces with four dice. The three terms $a^4+4a^3b+6a^2b^2$ of the fourth power of the binomial $a+b$, in which the indices of a equal

equal or exceed this number of times that the ace is to be thrown, will denote the number of chances whereby two aces may be thrown; fo that a being $= 1$, and $b = 5$, $a^4 + 4a^3b + 6a^2b^2$, will be $= 1 + 20 + 150 = 171$; and the whole number of chances, viz. $\overline{a+b}^4 = 1296$; conſequently the probability required will be expreſſed by $\frac{171}{1296}$. See Caſe 6. The probability of the contrary will be $\frac{1125}{1296}$; for in the two terms of the fourth power of $a + b$, $4a^3b + b^4$, a is found only once in the firſt, and not at all in the ſecond; therefore, theſe will expreſs the number of chances againſt throwing two aces, which is $= 500 + 625 = 1125$. And the probability of ſucceeding will be $1 - \frac{1125}{1296} = \frac{171}{1296}$, as before. And univerſally, the laſt term of any power $\overline{a+b}^n$ being b^n, and the laſt but one $na^{n-1}b$, in neither of which a enters, it follows that the two laſt terms of that power expreſs the number of chances that are contrary to the throwing of two aces, in any number of throws denominated by n; and that the probability of throwing two aces will be $1 - \frac{na^{n-1}b + b^n}{\overline{a+b}^n} = \frac{\overline{a+b}^n - na^{n-1}b - b^n}{\overline{a+b}^n}$. And likewiſe, in the three laſt terms of the power $\overline{a+b}^n$, every one of the indices of a will be leſs than three, and conſequently thoſe laſt terms will ſhew the number of chances that are contrary to the throwing of an ace three times in any number of throws n; and the ſame rule will hold perpetually. If the chances for failing and happening in any particular trial be reſpectively repreſented by a and b, the preceding rules may be applied to the happening or failing of any other kind of event in any number of times.

12. If A lays a wager that a certain event will happen t times in n trials, and B lays to the contrary, and the number of chances of happening and failing in one trial be reſpectively a and b, the number of chances whereby B may win his wager will be determined by as many of the laſt terms of the power $\overline{a+b}^n$ expanded, as are repreſented by t. And the number of chances whereby A may be a winner, will be expreſſed by as many of the firſt terms of the ſame power as are equal to $n - t$, n being allowed equal to $n - t + 1$, becauſe B, by laying againſt A's winning t times, does in effect lay that he will not win above $t - 1$ times: but the whole number of winnings and loſings being n, $n - t - 1$, or $n - t + 1$, will be the number of times which B himſelf undertakes to win.

13. If A and B, being at play, reſpectively want t and f games of being up, and their reſpective chances for winning any one game be as a to b; raiſe the binomial $a+b$ to a power whoſe index is $t+f-1$, and the number of chances whereby they may reſpectively win the ſet, will be in the ſame proportion as the ſum of ſo many of the firſt terms as are expreſſed by f, to the ſum of ſo many of the laſt terms as are expreſſed by t; for when A and B reſpectively undertook to win t games and f games, and t repreſented the whole number of games, in the preceding caſe, f was $= n - t + 1$; and, therefore, $t + f = n + 2$, and $n = t + f - 1$, which will, conſequently, repreſent the power to which $a+b$ muſt be raiſed. E. g. let $t = 3$, $f = 3$, $n = 5$, and $b = 5$ then raiſe $a+b$ to the power repreſented by $t+f-1$, i. e. to the ninth power, and the ſum of the firſt three terms will be to the ſum of the three laſt, in the proportion of the reſpective chances whereby A and B may win the ſet. The chances of B, or the three laſt terms, are $a^6b^3 + 9a^5b^4 + 36a^4b^5 = 37812500$, which, divided by $\overline{a+b}^9 = 1342177728$, gives the fraction $\frac{37812500}{1342177728} = \frac{2453125}{33554432}$, expreſſing the probability of B's winning; and this fraction, ſubtracted from unity, or $1 - \frac{2453125}{33554432} = \frac{31101307}{33554432}$, will expreſs the probability of A's winning; and the odds in favour of A are to the proportion of 31101307 to 2453125, or nearly as 23 to 9. See Caſe 10.

Examples often occur, as in this caſe, in which it is required to ſum up ſeveral terms of a high power of the binomial $a+b$, and to divide their ſum by that power: the moſt convenient method of doing this is to write 1 and q for a and b, having taken $q : 1 :: b : a$, and to uſe a table of LOGARITHMS. Thus, in the preceding example, $a = 5$, $b = 5$, therefore $q = \frac{5}{5} = 1$; and the quantity $\frac{b^5 + 9a^5b^4 + 36a^4b^5}{\overline{a+b}^9}$ becomes $\frac{1^5 + 9 \cdot 1^4 + 36 \cdot 1^5}{\overline{1+1}^9} = \frac{1^5 + 9 \cdot 1^4 + 36 \cdot 1^5}{\overline{1+1}^9}$; but the factor $1^5 + 9 \cdot 1^4 + 36 \cdot 1^5$ is $= \frac{35}{9} + \frac{45}{3} + 36 = \frac{484}{9}$, and its logarithm is the logarithm of $484 -$ log. $9 = 1.7306025$

To which add the log. of 1^9,
or $7 \times$ log. $5 -$ log. $3 =$ 1.5529420
And from the ſum — — 3.2835445
Subtract. the log. of $\overline{1+1}^9$
or $9 \times$ log. $2 -$ log. $3 =$ 3.8377183
And the remainder — — 1.4458262

will be the logarithm of B's chance, viz. 0.2817251; and the complement of this to unity, or 0.7182749, will be the chance of A. See another method of reducing ratios in large numbers to their leaſt exacteſt terms, under RATIO.

The following TABLE ſhews the odds of winning, when the number of games wanting does not exceed ſix, and the ſkill of the contenders is equal.

Games wanting.	Odds of winning.	Games wanting.	Odds of winning.	Games wanting.	Odds of winning.
1,2	3:1	2,5	1193	3,5	93.49
1,3	7:1	2,4	26.0	3,6	219.37
1,4	15:1	2,5	57.7	4,5	163.93
1,5	31:1	3,3	120.8	4,6	382.18
1,6	63:1	3,4	42.22	5,6	638.366

14. *To aſſign the probability of throwing two aces, and no more, with four dice at one throw.* From the number of chances whereby one ace or more may be thrown, ſubtract the number of chances whereby two aces or more may be thrown, and the remainder will be the number of chances for throwing one ace, and no more. Having raiſed the binomial $a+b$ to its fourth power, which is $a^4 + 4a^3b + 6a^2b^2 + 4ab^3 + b^4$, it is evident, that the four firſt terms expreſs the number of chances for throwing one ace or more, and the three firſt terms expreſs the number of chances for throwing two aces or more; and, therefore, the ſingle term $4ab^3$ expreſſes the number of chances for throwing one ace and no more; and the probability required will be $\frac{4ab^3}{\overline{a+b}^4} = \frac{500}{1296} = \frac{125}{324}$.

See Caſe 7.

When it is required to aſſign the chances for throwing any number of aces, and no more than that number, one ſingle term of the power $\overline{a+b}^n$ will always anſwer the queſtion; and this term may be expeditiouſly found, ſuppoſing n to be the number of dice, and t the preciſe number of aces to be thrown, when t is leſs than $\frac{1}{4}n$, by writing as many terms of the ſeries $\frac{n}{1}, \frac{n-1}{2}, \frac{n-2}{3}, \frac{n-3}{4}$, &c. as there are units in t; and when t is greater than $\frac{1}{4}n$, by writing as many of them as there are units in $\frac{1}{4}n - t$; then multiplying all thoſe terms together, and multiplying the product by a^tb^{n-t}; and this laſt product will exhibit the term expreſſing the number of chances required. E. g. Let t be $= 3$, and $n = 10$; ſince t is leſs than $\frac{1}{4}n$, take three terms of the ſeries, which will be $\frac{10}{1}, \frac{9}{2}, \frac{8}{3}$; their product will be 120; and a^tb^{n-t}, a being $= 1$, $b = 9$, &c. will be $= 60429691$; and $60429691 \times 120 = 7251562280$, which expreſſes the number of chances required. Divide this by $\overline{a+b}^{10} = 10000000000$, and the quotient 0.7251562280, will expreſs the probability of throwing preciſely three aces with ten dice; ſubtract this quotient from unity, and the remainder 0.2748437720 will expreſs the probability of the contrary; and the odds againſt throwing preciſely three aces with ten dice, are 0.2748437720 to 0.7251562280, or nearly 64 to 5.

Having thus given as compendious a view as poſſible of the principles and rules of *gaming*, from Mr. De Moivre's Introduction, we ſhall ſelect a few problems, for the farther illuſtration and exerciſe of theſe principles and rules.

Prob. I. *If A and B play with ſingle hands, and A can give B two games out of three; what is the proportion of their ſkill, or what are the odds, that A can get any one game aſſigned?* Let the proportion of odds be as n to 1; now ſince A can give B two games out of three, A and B, upon an equality of play, undertake to win three games together; but the probability of his winning the firſt time is $\frac{n}{n+1}$, and the probability of his winning three times together is $\frac{n}{n+1} \times \frac{n}{n+1} \times \frac{n}{n+1} = \frac{n^3}{\overline{n+1}^3}$, See EXPECTATION. But, as A and B are ſuppoſed to play on equal

equal terms, the probability which A has of winning three games together ought to be expressed by $\frac{1}{2}$; and, therefore, $\frac{x^3}{x^3+1^3} = \frac{1}{2}$, or $2x^3 = x^3+1^3$; and, extracting the cube root on both sides, $x\sqrt[3]{2} = x+1$; and $x\sqrt[3]{2}-x = 1$; therefore $x = \frac{1}{\sqrt[3]{2}-1}$; and the odds in favour of A's getting any game aliigned, are as $\frac{1}{\sqrt[3]{2}-1}$ to 1, or as 1 to $\sqrt[3]{2}-1$, i. e. as 50 to 17 very nearly.

Prob. II. *To find in how many trials any event will probably happen, for whose happening A and B may lay a wager on even terms.* Let the number of chances for its happening in any one trial be a, and the number of chances for its failing be b; and the number of trials x. By Case 12. a^x will represent the number of chances of the event's failing x times successively, and $\overline{a+b}^x$ the whole number of chances for happening or failing; and, therefore, $\frac{a^x}{\overline{a+b}^x}$, expresses the probability of the event's failing x times together, which is equal to the probability of its happening once at least in that number of trials; and either of these may be expressed by the fraction $\frac{1}{2}$; consequently, $\frac{a^x}{\overline{a+b}^x} = \frac{1}{2}$, or $a^x+b^x = 2a^x$; therefore, $x \times \log. a+b = x \times \log. b+\log. 2.$ and $x = \frac{\log. 2}{\log. a+b-\log. b}$. Again, suppose $a:b :: 1:q$, then the equation $a^x+b^x = 2a^x$, will be changed into $1+q^x = 2^x$, or $\frac{1+q^x}{2^x} = 2$, or $1+\frac{1}{q^x} = 2$. Therefore $x \times \log. 1+\frac{1}{q} = \log. 2$. If, in this equation, $q = 1$, x will also $= 1$; but if q differs from unity, substitute in the room of $\log. 1+\frac{1}{q}$ its value expressed in a series, viz.

$$\frac{1}{q}-\frac{1}{2q^2}+\frac{1}{3q^3}-\frac{1}{4q^4}+\frac{1}{5q^5}-\frac{1}{6q^6}, \text{ &c. and we shall have the equation } \frac{x}{q}-\frac{x}{2q^2}, \text{ &c.} = \log. 2.$$

If q be infinite, or large in respect to unity, the first term of the series will be sufficient; and we shall have the equation $\frac{x}{q} = \log. 2$, or $x = q \times \log. 2$. Then taking the hyperbolic logarithm of 2, which is 0.6931, &c. or 0.7 nearly, x will be equal to $0.7q$ nearly. Thus the limits of the ratio of x to q are assigned; for it begins with unity, and terminates at last in the ratio of 7 to 10 very nearly. This value of x may be assumed in all cases, whatever be the value of q.

Ex. 1. *To find in how many throws one may undertake with an equality of chance to throw two aces with two dice.* The number of chances upon two dice being 36, of which there is but one chance for two aces, the number of chances against it is 35; multiply, therefore, 35 by 0.7, and the product 24.5 will shew that the number of required throws will be between 24 and 25.

Ex. 2. *To find in how many throws of three dice one may undertake to throw three aces.* The number of all the chances on three dice being 216, of which there is but one chance for three aces, and 215 against it; multiply 215 by 0.7, and the product 150.5 will shew that the number of required throws will be 150 nearly. See Lottery.

Prob. III. *To find how many chances there are upon any number of dice, each of them having the same number of faces, to throw any given number of points.* Let $p+1$ be the given number of points, n the number of dice, and f the number of faces in each dice: let $f-f=0$, $2f-f=f$, $3f-f=2f$, $4f-f=3f$, &c. The number of chances required will be,

$$+\frac{p}{1}\times\frac{p-1}{2}\times\frac{p-2}{3} \text{ &c.}$$

$$-\frac{p}{1}\times\frac{p-1}{2}\times\frac{p-2}{3} \text{ &c.} \times \frac{n}{1}$$

$$+\frac{p}{1}\times\frac{p-1}{2}\times\frac{p-2}{3} \text{ &c.} \times \frac{n}{1}\times\frac{n-1}{2}$$

$$-\frac{p}{1}\times\frac{p-1}{2}\times\frac{p-2}{3} \text{ &c.} \times \frac{n}{1}\times\frac{n-1}{2}\times\frac{n-2}{3}$$

$$+ \text{ &c.}$$

And these series ought to be continued till some of the factors in each product become either $=0$, or negative: and so many factors are to be taken in each of the products $\frac{p}{1}\times\frac{p-1}{2}$ &c. $\frac{p}{1}\times\frac{p-1}{2}$ &c. as there are units in $n-1$. See the demonstration of this rule in De Moivre's Doctrine of Chances, p. 41.

Ex. 1. *To find how many chances there are for throwing fifteen points with five dice.* Here $p+1 = 16$ and $n = 5$; and the foregoing series will be

$$+\frac{15}{1}\times\frac{14}{2}\times\frac{13}{3} = +455$$

$$-\frac{9}{1}\times\frac{8}{2}\times\frac{7}{3}\times\frac{5}{1} = -336$$

$$+\frac{3}{1}\times\frac{2}{2}\times\frac{1}{3}\times\frac{5}{4}\times\frac{3}{2} = +6. \text{ And } 455-336+6 = 125 \text{ is the number of chances required.}$$

Ex. 2. *To find the number of chances for throwing fifteen points with six dice.* The series will be

$$+\frac{14}{1}\times\frac{13}{2}\times\frac{12}{3}\times\frac{11}{4}\times\frac{10}{5} = +2002$$

$$-\frac{8}{1}\times\frac{7}{2}\times\frac{6}{3}\times\frac{5}{4}\times\frac{6}{5} = -336. \text{ And } 2002-336 = 1666 \text{ the number required.}$$

In like manner it may be found that the number of chances for throwing twenty-seven points with six dice is also 1666. We may observe in general, that all the points equally distant from the extremes, i. e. from the least and greatest points that are upon the dice, have the same number of chances; by which they may be produced: thus, in finding the number of chances for throwing twenty-seven points with six dice, let 27 be subtracted from 42, the sum of the extremes 6 and 36, and the remainder being 15, we may infer that the number of chances for throwing twenty-seven points is the same as for throwing fifteen points.

Ex. 3. *To find in how many throws of six dice one may undertake to throw fifteen points precisely.* The number of chances for throwing fifteen points being 1666, and the whole number of chances upon six dice being 46656, it follows that the number of chances for failing is 44990; therefore, dividing 44990 by 1666, and the quotient is 27 nearly; multiply 27 by 0.7, and the product 18.9 will shew that the number of throws required will be very nearly 19.

Prob. IV. *To find how many trials are necessary to make it equally probable that an event will happen twice.* Let a, b, and x, be as in Prob. II. Then by case 12. $a+b^{x-1}$ is the number of chances whereby the event may fail, and $\overline{a+b}^x$ the whole number of chances whereby it may happen or fail, and, therefore, the probability of its failing is $\frac{a+b^{x-1}}{\overline{a+b}^x}$; but, as the probabilities of happening and failing are equal, we shall have the equation $\frac{a+b^{x-1}}{\overline{a+b}^x} = \frac{1}{2}$, or $a+b^{x-1} = 2a^x+2xa^{x-1}b$; or making $a:b :: 1:q$, $1+\frac{1}{q^{x-1}} = 2+\frac{2x}{q}$. Let $q = 1$, and x will be $= 3$. But if q be infinite, and $\frac{x}{q} = 2$; and $x = \log. 2+\log. 1+2$, and the value of x will be found $= 1.6\,78$ nearly; therefore the value of x will always be between the limits 3 and 1.678 &c. but will soon converge to the last of these limits; and if q be not very small, x may in all cases be supposed $= 1.678$ &c. but if x be suspected to be too little, substitute this value in the original equation $1+\frac{1}{q^{x-1}} = 2+\frac{2x}{q}$, and note the error; if it be worth regarding, increase x a little the value of x, and substitute this new value in the aforesaid equation, and noting the new error, the value of x may be sufficiently corrected by the rule of double false position.

Ex. 1. *To find in how many throws of three dice one may undertake to throw three aces twice.* The number of all the chances on three dice being 216, of which there are 215 against throwing three aces; multiply, therefore, 215 by 1.678, and the product 360.8 will give the number of required throws.

Ex. 2. *To find in how many throws of six dice one may undertake to throw fifteen points twice.* The number of chances for throwing fifteen points is 1666, and the number of chances for failing 44990. See Prob. III. divide 44990 by 1666, and the quotient will be 27 nearly; therefore the chances for throwing and missing fifteen points are as 1 to 27 respectively; multiply 27 by 1.678, and the product 45.3 will be the number of required throws. See Lottery.

Prob. V. *To find how many trials are necessary to make it equally probable that an event will happen 3, 4, 5, &c. times.*

finite. Let n, b, and x, be as before; and $a : b :: 1 : \frac{b}{a}$; then $1+\frac{1}{f}^{n} = 2\times 1+\frac{n}{f}+\frac{n}{1}\times\frac{n-1}{2f^2}$ in the case of the triple event; and $1+\frac{1}{f}^{n} = 2\times 1+\frac{n}{f}+\frac{n}{1}\times\frac{n-1}{2f^2}+\frac{n}{1}\times\frac{n-1}{2}\times\frac{n-2}{3f^3}$ in case of the quadruple event, &c. Then if g in the first equation be supposed $= \infty$, x will be $= 5 \cdot 4$ if g be infinite, or very large in respect to unity, the aforesaid equation, making $\frac{n}{f} = z$, will become $x = \log. 2 + \log. 1 + z + \frac{1}{2}zz$; and z will be found nearly $= 2.6755$, and x will always be between 5 and 2.6754. In the second equation, if g be $= \infty$, x will be $= 7\,9$; but if g be infinite, or very large in respect to unity, z will be $= \log. 2 + \log. 1 + z + \frac{1}{2}zz + \frac{1}{3}z^3$; and x will be found nearly $= 3.67319$, and x will be between $7\,9$ and 3.67194.

A Table of the Limits.

The value of x will always be

For a single event, between	$1\,9$	and 0.6931
For a double event, between	$3\,9$	and 1.6789
For a triple event, between	$5\,9$	and 2.6755
For a quadruple event, between	$7\,9$	and 3.6729
For a quintuple event, between	$9\,9$	and 4.6709
For a septuple event, between	$11\,9$	and 5.6689

&c.

And if the number of events contended for, as well as the number f, be pretty large in respect to unity; the number of trials required for those events to happen n times will be $\frac{2n-1}{2}f$, or barely nf.

Prob. VI. *Two gamesters* A *and* B, *each having twelve counters, play with three dice, on condition that if eleven points come up,* B *shall give one counter to* A; *if fourteen points come up,* A *shall give one counter to* B; *and that he shall be the winner who shall forneft get all the counters of his adverfary: what is the probability that each of them has of winning?* Let p be the number of counters of each, and a and b the number of chances they have refpectively for getting a counter at each caft of the dice; their probabilities of winning are refpectively as a to b: and p being $= 12$, and $a = 27$, and $b = 15$, by Prob. III. the probabilities of winning are refpectively as 27^{12} to 15^{12}, or as 9^{12} to 5^{12}, or as 282429536481 to 244140625. See the demonftration of this rule in Doctrine of Chances, p. 52.

Prob. VII. *Two gamefters* A *and* B *lay by twenty-four counters, and play with three dice in this condition, that if eleven points come up,* A *fhall take one counter out of the heap; if fourteen,* B *fhall take one, and he fhall be reputed the winner who fhall forneft get twelve counters.*

This problem differs from the preceding, in that the game muft neceffarily end in twenty-three throws, whereas in the former the play may be protracted, on account of the reciprocations of lofs and gain, which deftroy one another. Let a and b repreſent the proportion of the chance for throwing 11 and 14; and raiſe $a+b$ to the twenty-third power, or to a power whoſe index is the number of all the counters wanting one, and the 12 firſt terms of that power will be to the 12 laſt in the ſame proportion as the probabilities of winning.

Prob. VIII. *Three gamefters* A, B, *and* C, *out of a heap of twelve counters, of which four are white and eight black, draw blindfold one counter at a time, in this manner:* A *begins to draw,* B *follows* A, C *follows* B; *then* A *begins again; and they continue to draw in the ſame order, till one of them, who is to be reputed the winner, draws the firſt white: what are their reſpective probabilities of winning?*

Let n be the number of counters, a the number of white, and b the number of black, and 1 the ſtake or ſum played for.

1. A has a chances for a white counter, and b chances for a black one; and, therefore, the probability of his winning is $\frac{a}{a+b} = \frac{a}{n}$; and his expectation on the ſtake 1, when he begins to draw is $\frac{a}{n}\times 1 = \frac{a}{n}$: now $\frac{a}{n}$ being taken out of the ſtake, there will remain $1-\frac{a}{n} = \frac{n-a}{n} = \frac{b}{n}$.

2. B has a chances for a white counter, and the number of remaining counters is $n-1$; therefore his probability of winning will be $\frac{a}{n-1}$, and his expectation on the remaining ſtake $\frac{b}{n}$ will be $\frac{ab}{n\times n-1}$: ſubtract $\frac{ab}{n\times n-1}$ from $\frac{b}{n}$, and the remaining ſtake will be $\frac{b}{n}-\frac{ab}{n\times n-1} = \frac{nb-b-ab}{n\times n-1}$; but $nb-ab=bb$; therefore it will be $\frac{b\times b-1}{n\times n-1}$.

3. C has a chances for a white counter, and the number of remaining counters is $n-2$; therefore his probability of winning will be $\frac{a}{n-2}$, and his expectation in the remaining ſtake will be $\frac{b\times b-1\times a}{n\times n-1\times n-2}$.

4. A may have out of the remainder the ſum $\frac{b\times b-1\times b-2\times a}{n\times n-1\times n-2\times n-3}$, &c. till the whole ſtake be exhauſted.

Wherefore write down the ſeries $\frac{a}{n}+\frac{b}{n-1}\,P+\frac{b-1}{n-2}\,Q+\frac{b-2}{n-3}\,R+\frac{b-3}{n-4}\,S$, &c. in which P, Q, R, S, &c. denote the preceding terms, and take as many terms of this ſeries as there are units in $b+1$ (for b repreſenting the number of black counters, the number of drawings cannot exceed $b+1$); then the ſums of the firſt, fourth, ſeventh, &c. terms, of the ſecond, fifth, eighth, &c. terms, and of the third, ſixth, &c. terms will be the reſpective expectations of A, B, C; or, as the ſtake is fixed, theſe ſums will be proportional to their reſpective probabilities of winning. Let n, then, in the caſe of this problem, $=12$, $a=4$, and $b=8$; and the general ſeries will become $\frac{4}{12}+\frac{8}{11}\,P+\frac{7}{10}\,Q+\frac{6}{9}\,R+\frac{5}{8}\,S+\frac{4}{7}\,T+\frac{3}{6}\,U+\frac{2}{5}\,X+\frac{1}{4}\,Y$; or, multiplying the whole by 495 in order to take away the fractions, the ſeries will be $165+120+84+56+35+20+10+4+1$: and A will have $165+56+10=231$, B, $120+35+4=159$, and C, $84+20+1=105$; therefore their reſpective probabilities of winning will be proportional to the numbers 231, 159, and 105, or 77, 53, and 35.

Prob. IX. A *and* B *having twelve counters, four of them white, and eight black;* A *wagers with* B, *that taking out ſeven counters, blindfold, three of them ſhall be white: what is the ratio of their expectations?* 1. Seek how many caſes there are for ſeven counters to be taken out of 12; they will be found from the doctrine of combinations, to be 792.

$$\frac{12}{1}\times\frac{11}{2}\times\frac{10}{3}\times\frac{9}{4}\times\frac{8}{5}\times\frac{7}{6}\times\frac{6}{7} = 792.$$

2. Set aſide three white ones, and find all the caſes wherein 4 of the eight black ones may be combined therewith; they will be found to be 70.

$$\frac{8}{1}\times\frac{7}{2}\times\frac{6}{3}\times\frac{5}{4} = 70.$$

And ſince there are 4 caſes in which 3 white may be taken out of four; multiply 70 by 4: thus the caſes, wherein three whites may come out with four blacks, are found to be 280.

3. By the common laws of *gaming*, he is reputed conqueror, who produces an even number than he undertook to do, unleſs the contrary be expreſly agreed on; and therefore, if A take out 4 whites with 3 blacks, he wins. Set aſide 4 whites, and then find all the caſes wherein 3 of the 8 blacks may be combined with 4 whites: theſe caſes will appear to be 56.

$$\frac{8}{1}\times\frac{7}{2}\times\frac{6}{3} = 56.$$

4. A, therefore, has $280+56=336$ chances, whereby he may win; which, ſubtracted from the whole number of chances 792, leaves 456, the number of chances wherein he may loſe. Divide 336 by 792, and the quotient $\frac{336}{792} = \frac{14}{33}$ will expreſs the probability of A's winning; and $1-\frac{14}{33} = \frac{19}{33}$ the probability of his loſing; and therefore the odds againſt taking 3 white counters are 19 to 14.

From the ſolution of this problem it appears, that, if a be $=$ the number of white counters, b the number of black, n the whole number $= a+b$, c the number of counters to be taken out of n, and p the number of white counters to be found preciſely in c, then the number of chances for taking none of the white, or one ſingle white, or two white and no more, or three white and no more, or four white and no more, &c. will be expreſſed

preſſed by $1 \times \frac{a}{1} \times \frac{a-1}{2} \times \frac{a-2}{3} \times \frac{a-3}{4}$, &c. $\times \frac{b}{1} \times \frac{b-1}{2} \times \frac{b-2}{3}$, &c. continued till the number of terms in which there is a be equal to p, and the number of terms in which there is b be equal to $q-p$. And the number of all the chances for taking a certain number c of counters out of the number n is expreſſed by the ſeries $\frac{n}{1} \times \frac{n-1}{2} \times \frac{n-2}{3}$ &c. continued to as many terms as there are units in c, for a denominator. E. gr. Reſume the ſuppoſition of the problem, only that of the ſeven counters drawn, there ſhall not be one white; and let $p=0$, and $c=1=7-6=n-1$; then taking one of the firſt ſeries and 7 terms of the ſecond, the number of chances will be 1×84; the ratio of which to all the 99 that can be taken out of 12 is $\frac{84}{792} = \frac{1}{99}$: therefore the odds that there ſhall be one or more white counters among the 7 which are drawn are 98 to 1. The probability of drawing one white counter and no more will be $\frac{112}{792} = \frac{14}{99}$, or the odds 85 to 14: the probability of drawing all the 4 white among the 7 will be $\frac{56}{792} = \frac{7}{99}$, or the odds 92 to 7. If n and c were large, the foregoing method would be impracticable; and, therefore, the following theorem may be uſed. Let n, c, and p be as before; and make $n-c=d$. The probability of taking preciſely the number p of white counters will be

$$\frac{c \times c-1 \times c-2 \times c-3 \times \&c. \times d \times d-1 \times d-2 \times \&c.}{1 \times 2 \times 3 \times 4 \times \&c. \times n \times n-1 \times n-2 \times n-3 \times \&c.}$$

Note, the firſt ſeries of the numerator contains as many terms as there are units in p; the ſecond as many as there are units in $a-p$; and the third as many as there are units in b; and the denominator as many as there are units in c. See LOTTERY.

To avoid tireſome prolixity in this article, we muſt deſiſt from farther inveſtigations; which, to the following problems grow very long, and more perplexed. In the reſt, therefore, we ſhall content ourſelves to give the anſwer, or reſults, without the proceſs of arriving at it; which may be of uſe, as it furniſhes to many data, from whence, as ſtandards, we may be enabled occaſionally to judge of the probability of events of the like kinds though without letting the mind into the preciſe manner and reaſon thereof.

Prob. X. *A and B play with two dice on this condition, that A ſhall win, if he throws ſix; and B, if he throws ſeven: it is here the firſt throw, in lieu of which B is to have two throws; and both to continue with two throws each turn, till one of them wins: What is the ratio of the chance of A, to that of B?* *Anſ.* As 10355 to 12276.

Prob. XI. *If any number of gameſters, A, B, C, D, E, &c. equal in point of dexterity, deſpoſit each one piece of money; and engage, in this condition, that two of them, A and B, beginning the game, which ever of them ſhall be overcome, ſhall give place to the third C, who is to play with the conqueror; and the conqueror here to be taken up by the fourth man D; and thus on, till ſome one, having conquered them all round, draws the ſtake: what is the ratio of their reſpectancies?* This problem, Mr Bernouilli ſolves analytically. Here, calling the number of gameſters $n+1$, he finds that the probabilities of any two immediately following each other in the courſe of playing, are in the ratio $1+2^n$ to 2^n; and therefore the expectancies of the ſeveral gameſters, A, B, C, D, E, &c. are in a geometrical progreſſion $1+2^n : 2^n : 1 : 2^{-n} : 2^{-2n}$, &c. Hence it is eaſy to determine the ſtate of the probabilities of any two gameſters, either before the game, or in the courſe thereof. If, e. gr. there be three gameſters, A, B, C, then $n=2$ and $1+2^n : 2^n : 1 :: 5 : 4 : 1$; that is, their ſeveral probabilities of winning, before A have overcome B, or B, C, are as the numbers 5, 4, 1; and therefore their expectancies are $\frac{5}{14}$, $\frac{5}{14}$, $\frac{4}{14}$: for all of them taken together muſt make 1, or abſolute certainty. After A has overcome B, the probabilities for A, B, and C, will be $\frac{1}{7}$, $\frac{2}{7}$, $\frac{4}{7}$, as in the anſwer above. If there be four gameſters, A, B, C, D, their probabilities from the beginning will be as 81, 81, 72, 64. After A has beat B, the ſeveral probabilities of B, D, C, A, will be as 25, 32, 36, 56 reſpectively. After A has beat B and C, the probabilities of C, B, D, A, will be as 16, 18, 28, 87.

Prob. XII. *Three gameſters, A, B, and C, whoſe dexterities are equal, deſpoſit each one piece, and engage upon theſe terms: that two of them ſhall begin to play, and that the vanquiſhed party ſhall give place to the third, who is to take up the conqueror; and the ſame condition to go round: each perſon when vanquiſhed, forfeiting a certain ſum to the main ſtake; which ſhall be all ſtarpt by the perſon who firſt beats the other two ſucceſſively. Now much, now, is the chance of A, and B, better or worſe than that of C?* 1. If the forfeiture be to the ſum each perſon firſt depoſited, as 7 to 6, the gameſters are upon an equal footing. 2. If the forfeiture be in a leſs ratio to the depoſit, A and B are on a better footing than C; if in a greater ratio, the advantage is on the ſide of C. 3. If there were no fines, the probabilities of winning would be proportional to the expectations, and the expectations, after the firſt game, would be $\frac{12}{7}$, $\frac{6}{7}$, $\frac{2}{7}$, the firſt belonging to B, the ſecond to C, and the third to A; and, therefore, dividing the ſum of the probabilities belonging to A and B into two equal parts, the probabilities of winning would be proportional to the numbers 5, 4, 5; and it is 5 to 2 before the play begins that either A or B win the firſt, or 5 to 4 that one of them who ſhall be fixed upon win it. 4. If three gameſters, A, B, and C, are engaged in a *pool*, and have not time to play it out, but agree to divide (.) the ſum of the ſtake and fines, in proportion to their reſpective chances; $\frac{5}{7}$ will be the ſhare of B, who has got one game: $\frac{2}{7}$ is that of C, who ſhould come next in, and $\frac{1}{7}$ the ſhare of A, who was laſt beat.

M. Bernouilli gives an analytical ſolution of the ſame problem, only made more general; as not being confined to three gameſters, but extending to any number at pleaſure.

Prob. XIII. *A and B, two gameſters of equal dexterity, play with a given number of bouts, after given time, A wants 1 of being up, and B 3: what is the ratio of their chances?* A's expectancy is worth $\frac{7}{8}$ of the ſtake, and B's only $\frac{1}{8}$ ſo that their chances are as 7 to 1.

Prob. XIV. *Two gameſters, A and B, of equal dexterity, are engaged in play, on this condition, that as often as A exceeds B, he ſhall give him one piece of money; and that B ſhall do the like, as often as A exceeds him; and that they ſhall not leave off till one has won all the other's money: and now having four pieces, two by-ſtanders, R and S, lay a wager on the number of turns in which the game ſhall be finiſhed;* viz. *R, that it ſhall be over in ten turns: what is the value of the expectancy of S?* $\frac{560}{1024}$, or $\frac{35}{64}$ of the wager; or it is to that of R as 560 to 464; and ſubtracting $\frac{35}{64}$ from 1, the remainder $\frac{29}{64}$ will expreſs the probability of the play ending in ten games; and it is as 35 to 29. If two equal gameſters play together, that there will not be four ſtakes loſt on either ſide in ten games.

If each player has 5 pieces, and the wager were, that the game ſhall end in ten turns, and the dexterity of A were double that of B, the expectancy of S would be $\frac{3800}{6561}$.

If each gameſter have 4 pieces, and the ratio of the dexterities be required to make it an even wager, that the game ſhall end in four turns, it will be found that the one muſt be to the other as 5.274 to 1. And if the ſkill of either be to that of the other as 13.407 to 1, it is a wager of three to 1, that the play will be ended in four games.

If each gameſter have 4 pieces, and the ratio of their dexterities be required to make it an even lay, that the game ſhall be ended in 6 turns, the anſwer will be found to be as 2.576 to 1.

Prob. XV. *Two gameſters, A and B, of equal dexterity, having agreed not to leave off playing till ten games are won, a ſpectator, R, lays a wager with another, S, that by that time or before, A ſhall have beat B by three games: what is the value of the expectancy of R?* $\frac{320}{1024}$, or $\frac{11}{32}$ of the ſame wager; or it is to that of S, as 352 to 672. See BASSET, HAZARD, LOTTERY, PHARAON, PIQUET, QUADRILLE, RAFFLING, and WHIST.

GAMITES *lapis*, the *marriage ſtone*, a ſtone of a very ſingular kind deſcribed by Pliny, and ſome other of the ancients; he ſays it was of a white colour, and that it had in it the figure of two hands mutually ſalluting one another, which made it a ſymbol of that ſtate. We know nothing of any ſuch ſtone at preſent in the world; and it is eaſy to conjecture, that in Pliny's time either the ſtone muſt have been factitious, or elſe fancy

fancy must have been very far stretched to make the resemblance.

GAMMADIUM, a triangular vestment used in the primitive church.

GAMMER-*land*. See the article GIMMER-*land*.

GAMMONING, on *ship-board*, are several turns of rope taken round the bowsprit, and reeved through holes in the knees of the head, for the greater security of the bow-sprit.

GAMMUT, or GAMUT, or GAM-*ut*, in *Music*, a scale, whereon we may learn to sound the musical notes, *ut, re, mi, fa, sol, la*, in their several orders, and dispositions.

The invention of this scale is owing to Guido Aretin, monk of Arezzo, in Tuscany, about the year 1009; though it is not so properly an invention, as an improvement on the DIAGRAM, or scale, of the ancients.

The *gammut* is also called the HARMONICAL HAND; because Guido first made use of the figure of the hand to arrange his notes on.

Finding the Greek diagram of too small extent, Guido added five more chords, or notes, to it; one below the *proslambanomenos*, or gravest note, of the ancients; and four above the note *hyperboreon*, or acutest.

The first he called *hypo-proslambanomenos*; and denoted it by the letter G, or rather the Greek Γ, *gamma*: which note being at the head of the scale, occasioned the whole scale to be called by the barbarous name *gamut*, or gammut.

Some say, Guido's intention, in calling his first note Γ, *gamma*, was to shew that the Greeks were the inventors of music; others, that he meant hereby to record himself, this being the first letter of his own name.

Guido's scale is divided into three series, or columns; the first called *mole*, or flat; the second *natural*; and the third *durum*, or sharp; as represented in the scheme *Tab. Music. fig.* 4. But, since his time, some alterations have been made therein. The use of this scale is, to make the passages, and transpositions, from *B* molle, to *B* durum, by means of the tones and semitones. The series of *B* natural, standing between the other two, communicates with both; so that, to name the chords of the scale by these syllables, if we would have the semitones in their natural place; viz. *b c*, and *e f*, then we apply *ut* to *g*; and after *la* we go into the series of *B* natural, at *fa*; and after *ut* of this we return to the former at *re*, and so on: or we may begin at *ut* in *c*, and pass into the first series at *mi*, and then back to the other at *fa*; by which means the one transition is a semitone; viz. *la fa*; and the other a tone *la, mi*. To follow the order of *B* molle, we may begin with *ut* in *c*, or *f*; and make transitions after the same manner.

Hence came the barbarous names of *gammut, ure, bmi*, &c. But it is a perplexed work, with so many different syllables applied to every chord, to mark the places of the semitones; which the simple letters *a, b, c*, &c. do as well, and with more ease.

Several alterations have since been made in the *gammut*. M. le Maire, particularly, has added a seventh note; viz. *si*, and the English usually throw out both *ut* and *si*, and make the other five serve for all; as will be shewn under the article SOL-FA-ING.

GAMMUT, or GAMUT, is also the first or gravest note in the modern scale of music; the reason of which is shewn under the preceding article.

GANACHES, in the *Manage*, are the two bones, one on each side of the hinder part of the head, opposite to the neck, or nuffet of the head, which form the lower jaw, and give it motion. It is in this place that the glands or kernels of the strangles, and the glanders, are placed.

GANCHE, Fr. derived from the Italian *gancio, hook*, a kind of GALLOWS or gibbet used for the punishment of criminals in Turky. The executioner raises the condemned by means of a pulley, and suddenly slackening the rope, lets them fall on hooks of iron, which entangle and rend their bodies; in this condition they are left to die, and some have been known to languish for two or three days.

GANG, in the *Sea Language*, signifies a crew.

To man a boat is called, to *put a gang of men* (which is a company) into her; they are commonly called the *cockswain's gang*, who have the charge of her.

GANG-*fish*, a name given by some authors to a small fish caught in the German lakes, and sent in pickle into many parts of the world. The more usual name of this fish among writers is LAVARETUS.

The *gang-fish* is a species of the COREGONUS, distinguished by Artedi by the name of the *coregonus*, with the upper jaw longest and flat, and with fourteen rays in the back fin.

GANG, *&c.* See OX.

GANG-WAY is applied to all the several entrances, ways, or passages, from one part of the ship to the other.

Whatsoever is put in any of these passages is said to be laid or put in the *gang way*. See *Tab. Ship. fig.* 2. n. 22, 84, 94.

GANG-*way* also denotes that part of a ship's side, both within and without, by which the passengers enter and depart: it is for this purpose provided with a sufficient number of steps, or *cleats*, nailed upon the ship's side, nearly as low as the surface of the water: and sometimes furnished with a ladder, whose lower end projects from the ship's side, being secured in this position by man ropes.

GANG, *water*. See WATER-*gang*.

GANGILES, or GANGALES, a name given by some to the *lapis* ATITES, or eagle-stone.

GANGLIO, GANGLION, in *Surgery*, a small, hard, knotty tumor, generally moveable, and usually formed on the tendons or ligaments, in the external or internal part of the carpus, without any discolouring of the skin, or any sense of pain.

The word is Greek, γαγγλιον, which signifies the same. The tumor, when on the nerves, tendons, articulations, or any of the membranous parts, retains its name *ganglion*: every where else it is called *wen*.

The cause of the *ganglion* is a too great distention of the pores of the part, or the too great compression, or a laceration thereof; any of these occasion the nutritious juice to be there stopped, and retained; and even to exude, condense, and harden, into a tumor. The same effect is sometimes also produced by a bruise, hard labour, or the like. Most authors hold the cause of the *ganglion* to be a very heavy viscid pituita.

Authors in general who have treated of the *ganglion*, have referred it to the class of encysted tumors, supposing it to be enclosed in a membranous sack, in the manner of the atheromatous and steatomatous encysted tumors. Mr. Eller, in the memoirs of the Berlin Academy, gives a very different account of this tumor: he observed, that very bad symtoms often succeeded the extirpating the *ganglion*, in the way of the common encysted tumors, by the knife, and thence concluded, that they must be of a different nature and origin from those tumors. The matter contained in the ganglion is usually found to be of a gelatinous texture, like the jelly of hartshorn, and of no bad smell, or sharp taste, and the membrane which contains it always contracts itself at the base into a kind of neck, and is there intimately joined to, and united with the tendon on which it is placed. The appearance of the tendon, however, in the place where the *ganglion* adheres, never appears vitiated, nor any way different from other parts of it. Memoirs de Berlin, ann. 1748. p. 109. In order to understand rightly the original of the *ganglion* we are to consider, that every fibre of the muscle to which the tendon is affixed, and of whose fibres it indeed is only an elongation in a more straightened form, is, while in the muscle, covered with a delicate fine membrane, which leaves it as soon as it leaves the muscle to enter the composition of the tendon; and that all these membranes together form the general covering of the tendon, which intercedes in the joining of that part to the bone. This membrane would be rather an inconvenience than an useful covering to the tendons, if it did not separate a limpid and viscous juice, which constitutes the whole surface of the tendon, and facilitates its common motions. Anatomists in general have neglected to enquire into the nature and use of this membrane which covers the tendons, and therefore they have mistaken the origin of the *ganglion*, which is not to be understood without this previous knowledge of the part to which it is wisely owing.

When this membrane suffers with the tendon any external violence from blows, or violent extensions, it often bursts in some parts; and it necessarily follows, that the liquor it before contained must escape through the apertures, and it after this naturally lodges itself in the tunica adipofa of the skin; and as the liquor by degrees thereby in quantity, this tunic, or membrane, forms a part of a sack for the reception of it. As the viscous liquor continues to be voided through the apertures, the more fubtile parts of it by degrees escape, and the remainder forms the viscous and tough matter, which is found in opening the *ganglion*. In some cases, where the rupture of the membrane has been incomplete, the surface of it heals and forms the covering of the swelling; and in this case represents the meninges in an artery.

The *ganglion* is sometimes removed, and resolved by mere dry friction, long continued; and sometimes by friction with lotion: some chuse to apply a plate of lead, anointed with mercury; others use gum ammoniac, or the emplastic of vigo, with mercury. If these do not succeed, recourse is had to section.

Mr. Sharp has frequently succeeded by making an incision through the whole length of the *ganglion*, and at the same time dividing the ligament of the wrist, and afterwards dressing as in common wounds. Mr. Warner gives two instances of his effectually extirpating them: he recommends cutting away part of the cyst, and then digesting the rest away.

GANGLION, in *Anatomy*, denotes a tumor or knot frequently found in the course of the nerves: for wherever any nerve sends out a branch, or receives one from another, or where two nerves join together there is generally a *ganglion*, or knot, as may be seen at the beginning of all the nerves of the medulla spinalis, and in many other parts of the body. The *ganglions* of the intercostal nerves, first discovered by Eustachius, are oblong and very hard bodies; and their uses have not yet been satisfactorily ascertained. M. Lancisi, who has paid particular attention to this subject, supposes that they are muscles *sui generis*, and capable of dilatation and contraction; and intended to impel and accelerate the nervous spirits with such additional force, as he conceives to be necessary for producing motion in muscles subject to the will. In order to furnish an idea of the structure of other *ganglions*, he has particularly described and delineated that of the first cervical *ganglion*. However, Haller, and other eminent anatomists, have not been able to discover this muscular apparatus in the first cervical *ganglion*. Besides, *ganglions*, instead of being instruments subservient to the will, are almost peculiar to nerves distributed to parts, whose motions are altogether involuntary. The office of *ganglions* has been conjectured, both by Lancisi and Winslow, to be analogous to that of the brain, and, therefore, they have considered them as a kind of subsidiary brains formed for impressing motion on the animal spirits. *Ganglions* are formed generally on nervous cords resulting from the union of several different nerves; they abound with blood-vessels, and commonly exceed in bulk that of all the nerves and vessels which form to compose them; and hence Morgagni and others have concluded, that in *ganglions* the different nervous filaments are very intimately mixed, and form a nervous organization, on modifications of the medullary substance, so as to form new animal spirits, or alter the direction of those already brought thither. Dr. Johnstone, of Kidderminster, has not long since published observations and conjectures on the structure and uses of the *ganglions* of the nerves. With regard to their structure, he considers them as little brains, or germes, of the nerves detached from them, consisting of a mixture of cortical and nervous medullary substance, nourished by several small blood-vessels, in which various nervous filaments are collected, and here lining their reciliment parallel to each other, so that a new nervous organization probably takes place in them. As to their use, he supposes that they are instruments, by which the motion of the heart and intestines are, from the earliest to the latest periods of animal life, rendered uniformly involuntary; or, that they are the immediate organs of the nerves transmitted to organs moved involuntarily, and that they serve to check or restrain our volitions from extending to them. They are analogous to the brain in their office, and, being subordinate springs, or reservoirs of nervous power, seem capable of dispensing it, long after all communication with the brain is cut off. From these *ganglions*, as subordinate brains, the vital organs derive their nervous power, and continue to move during sleep: and to the same cause, as well as to its greater irritability, the motion of the heart, continued longer than that of the voluntary muscles in perfect apoplexies, is ascribed; and to the same cause, he apprehends, it is also owing, that the heart continues to move even after the spinal marrow and the intercostals in their descent along the neck are cut through, so that animals have sometimes survived this experiment for thirty hours. See Phil. Trans. vol. liv. p. 173. Art. 33. and vol. lvii. or Essay on the Use of the Ganglions of the Nerves, 1771.

GANGRENE, GANGRENA, in *Surgery*, is a dangerous degree of inflammation, wherein the parts affected begin to corrupt and putrefy; or a mortification, in its incipient state, while yet the part retains some sense of pain, and a share of the natural heat. By which this disease is distinguished from a *sphacelus*, or thorough mortification, where there is no sense or warmth left.

The word is Greek, Γαγγραινα, derived, by some authors, from the Paphlagonian γαγρα, a goat; it being the character of a goat to browse the grass all round, without shifting its place. It is justly, perhaps, to derive it from the Greek verb γραω, γραειν, *mandere, edere, I eat, consume.*

The *gangrene* is a disease chiefly affecting the skin and fat, which it corrupts, consumes, and turns black; and by degrees spreads and seizes the adjoining parts; and issues in a sphacelus, which is never cured without amputation.

It arises from a stoppage, or interception, of the circulatory motion of the blood; which, by this means, fails to furnish the part with the nutritious and spirituous juices necessary to preserve its warmth and life.

This interception of circulation, which is the proximate cause of the *gangrene*, is itself occasioned divers ways; as by large tumors, erysipelases, great inflammations, violent cold, tight bandages or compressions, sudden fluxions of some malignant humors, bites of venomous beasts, fractures, wounds, and ulcers ill managed, &c. It is distinguished by the colour of the flesh; which first turns pale, then dusky, or livid; and by its growing loose, and flabby, after being vehemently tense, which it was before. In the progress of the disease the part distils a fetid, discoloured water; and emits a cadaverous smell.

Upon the first seizure the skin turns pale; afterwards it becomes livid; vesications arise, and the colour, at length, changes to black; the flesh becomes fetid, tenacious, and moist; then wastes, and soon becomes insensible; the heat and pulsation of the part being likewise diminished. Shaw.

If, in a large wound, the tumor of the lips does not suppurate, nor any flux of matter, or inflammation, arise; if the lips do not swell, or, after swelling, grow lank and flaccid again on a sudden, it is reckoned a sure sign of an approaching *gangrene*.

When a *gangrene* proceeds from extreme cold, the part affected is first benumbed, or seized with a pricking pain: this is followed by a redness, which gradually changes to black.

When a tight bandage is the cause, a flaccidity of the part is joined to the insensibility thereof: when the scurvy, it often begins in the great toe, and appears in form of a blackish spot; which turns to a dry crust, succeeded by a stupor of the part, &c. When the bite of any venomous creature is the cause, a continual fever attends, &c. and pain is felt in the part; which usually brings on a syncope, or delirium; and pustules arise about the bite.

By the microscope a *gangrene* has been discovered to contain an infinite number of little worms, engendered in the morbid flesh; and which continually producing new broods, swarm, and over-run the adjacent parts.

To stop the progress of the *gangrene*, physicians prescribe, internally, sudorifics and alexipharmics; externally, decoctions of quick-lime, either simple, or with the addition of sulphur, mercurius dulcis, and spirit of wine camphorated.

When a *gangrene* seizes a part, the great care to be taken is to prevent, if possible, its terminating in a sphacelus. In strong habits it is always proper in this case first to bleed largely, and repeat it as occasion shall require; and it is a well necessary step in these cases, to be very careful in the beginning, to remove all violent external causes of inflammation; as too strict a bandage in wounds and fractures, all foreign bodies, which are accidentally lodged in the parts, as thorns, splinters, needles, and the like; and all improper external applications, such as oils and plasters, with cooling and astringent things; and especially in old or weak people, to keep up the failing strength by such diet as afford good and suitable juices for nourishment. If the patient is weak, and in years, and naturally of a cold habit; especially if he has lost much blood, and abounds in crudities, the most suitable diet for him will be soups and broths, made of chicken, or meat, with mace and other spices boiled in them; also draughts of cordial liquors, with yolks of eggs, cinnamon and sugar; eggs themselves poached and eaten soft; strong jellies of calves feet, hartshorn, and every shavings, and old and rich wines; or where the patient's circumstances will not afford these, and nothing particular forbids the use of malt liquors, fine ales not too stale may serve very properly.

With respect to medicines, the proper ones are the cordial tinctures, waters, and electuaries, as the confection of alkermes with spices and other cordial ingredients mixed in it; and teas, made of sage, scordium, and the like herbs, with the spices, or a few shavings of saffafras, or yellow saunders; for by these means, the stagnating blood will be greatly resolved and attenuated, and its sound and healthy parts will be retained in a due circulation, and its noxious ones discharged and dissipated: it is also of some service in these cases frequently to apply a sponge dipt in Hungary water to the nose, or to bind it to the wrists, or temporal arteries: the crumbs of rye-bread, mixed with powdered cloves, and steeped in strong vinegar, and afterwards made up into a ball, and held frequently to the nose, are also of no little service.

For patients who are of a more warm, sanguine, and bilious habit, soups and decoctions mixed with the acid juices of lemons, or other vegetable acid, are very proper strengtheners; as alſo barley gruel, mixed with syrup of lemons, or mulberries, or with jelly of currants, to be taken daily for the common drink. But in theſe caſes, when the pulſe is ſmall, and the patient weak, or before acculſtomed to wine, it may be allowable to mix a little wine with the gruel: Rhenish is of all wines the moſt proper on this occaſion, and a glaſs of that, or if neceſſary of a richer wine, may be given at proper intervals.

The temperate or cooling medicines, commonly given in fevers, may alſo be adminiſtered very properly in theſe caſes; but above all others, the bark is generally eſteemed the great internal remedy in this diſorder. To theſe muſt be added, the ſurgeon's utmoſt attention in the diſcharging the ſtagnating and corrupted blood from the parts, as ſoon as poſſible, and to prevent the neighbouring parts from being affected thereby; the principal methods of doing this are, while the proper internal medicines are given, to make ſcarifications as occaſion ſhall direct upon the parts affected, with the knife; theſe inciſions are to be made all lengthwiſe, and very numerous on the part, and are to be opened to a ſufficient depth; that not only the ſtagnating blood may be by that means diſcharged; but free way may be made by theſe openings, for the ingreſs of the medicinal applications. And laſtly, diſcutient, balſamic, and ſtimulating fomentations and cataplaſms are to be with great care applied to the affected parts, and frequently renewed. A very excellent fomentation on theſe occaſions is made by mixing with a pint of lime water, three ounces of camphorated ſpirit of wine, with half an ounce of ſpirit of ſal ammoniac, or of ſpirit of wine, with myrrh, aloes, and ſaffron infuſed in it, or ſpirit of wine camphorated, with a ſmall quantity of Venice treacle, and elixir proprietatis. A decoction of rue, wormwood, ſouthernwood and camomile flowers alſo, with an admixture of four ounces of Venice treacle, and two ounces of Caſtile ſoap, and half an ounce of ſal gem to the quart makes a very valuable fomentation: this ſhould be applied hot ſeveral times in a day, by means of doubled linen or woollen cloths dipped in it, and a laſting warmth may often be ſervicеably kept, by means of a brick made hot by boiling water, and applied afterwards, wrapped up in a linen cloth.

The poor may find a cheap domeſtic remedy in the pickle of cabbages, or in horſe or cow dung, boiled in vinegar, or wine if that can be had: theſe ſhould be applied warm, on linen or woollen cloths, and it is much better to ſleep them hot, by means of a hot brick or tile, than to be frequently opening and expoſing the part to the air to renew them. A very efficacious fomentation for a *gangrene* may be made of ſcordium, wormwood, and ſouthernwood, either ſeparate or mixed and boiled in ſea-water, or ſalt water, or vinegar, which ſhould be applied hot ſeveral times a day.

The more deſperate a *gangrene* is, and the nearer it approaches to a ſphacelus, the longer and deeper the ſcarifications muſt be made; they may now alſo if on the legs, arms, &c. be made tranſverſely, as well as longitudinally, down to the quick; and afterwards the injured parts are to be well rubbed and wetted with warm and ſtimulating medicines; and afterwards a penetrating and diſcutient cataplaſm is to be applied, that the blood in the vitiated parts may be reſtored as much as poſſible to its free and proper motion. A proper cataplaſm for this purpoſe may be made of a few handfuls of ſcordium, wormwood, feverfew, mallows, mint, and ſouthernwood, boiled in oxycrate to the conſiſtence of a cataplaſm and poultice, with half an ounce of ſal ammoniac, and two ounces of linſeed meal, with half an ounce of the infuſed oils of rue or camomile added afterwards to it; before this cataplaſm is applied to the part, it is always proper to mix with it a little Venice treacle, or elſe ſpirit of wine camphorated, to increaſe its virtue.

Theſe applications are beſt renewed about three times a day; if they are oftener, they expoſe the parts too much to injuries from the external air by ſo frequent uncovering them; if more ſeldom, it is poſſible changes may happen between, with which the ſurgeon ought to have been timely acquainted. Care however muſt be taken, either by hot bricks, or ſome like means, to keep the applications warm all the time they are on, for when ſuffered to cool upon the part, they are not only uſeleſs but very hurtful. Heiſt. Surgery, p. 215.

Dr. Le Cat in his letter concerning the cure of dry *gangrene*, obſerves, that the cauſe of theſe is the want of a flow of the arterial blood and ſpirits into the part affected, and therefore that the operation of ſcarification is not only uſeleſs, but pernicious: becauſe you thus increaſe the irritation of the ſolids, the conſtriction of the veſſels, the want of fluids and the exſiccation, and haſten death. The general indication which this diſtemper affords is to ſoften and relax the veſſels, and to draw thither the humors by topics, whilſt all internal remedies ſhould be given that are capable of bringing the blood and the ſpirits from the centre to the circumference: and if this method fails, amputation can be of no uſe; but death is inevitable. As this diſorder, by fars, ariſes from internal cauſes, its cure ſhould be chiefly attempted by internal remedies, and he accordingly adminiſters cordials, diaphoretics, and ſuch medicines as are capable of reviving the drooping ſpirits and quickening the circulation even to the extremities: to which ſhould alſo be added medicines adapted to the particular habit of each patient, which may have contributed to have brought on this particular ſpecies of *gangrene*. At the ſame time emollient, attractive, external remedies, moderately warmed with ſpices, applied to the part, concur to the ſame intention, by facilitating the flow of blood and ſpirits: but ſpirituous and aqueous topics, impregnated with volatiles, and charged with ſaline, active, and violently ſtimulating particles, and others in ſide in ordinary *gangrene*, are to be avoided like deadly poiſons. On the contrary, in humid *gangrene*, it is chiefly the return of the blood which is hindered and thereby the fluids are accumulated, that ſwell and diſtend the diſeaſed part: and this diſtemper, which characteriſes the humid *gangrene*, ſhews the neceſſity of ſcarifications and evacuations: after which ſtimulating tonics ſhould be applied. See the recital of caſes, in which his method has proved ſucceſsful in the Paſs. Tranſ. vol. xlvi. art. 16.

Belloſte preſcribes the following, as the moſt efficacious remedy known for *gangrene*: viz. quickſilver, diſſolved in double the quantity of ſpirit of nitre, or aqua fortis, a linen cloth being dipped therein, and applied to the *gangrenous* part. This alone, he aſſures us, was ſufficient. If the *gangrene* be occaſioned by an intenſe froſt, ſnow-water, or a linen cloth dipped in cold water, and applied to the part affected, Boerhaave directs as the beſt cure.

If the *gangrene* proceed to an utter ſphacelation, and be ſeated in any of the limbs or extreme parts, recourſe muſt be had to the operation of amputation.

GANGRINOS, in the *Materia Medica* of the ancients, a word uſed for foſſile ſalt; Myrepſus plainly uſes it in this ſenſe, and Fuchſius explains it by foſſile ſalt, called by the barbarous authors ſal gemmæ.

GANGUE, *Germ.* denotes the MATRIX of ores.

GANGYA, in the *Materia Medica*, a name by which ſome authors call the ſeſamum, or oily purging grain.

GANIMEDES, in *Chemiſtry*, a name given by ſome to white ſulphurs, raiſed by frequent ſublimation; theſe affected writers gave it this name from its being elevated by fire in the proceſs, as Ganymede is ſaid by the poets among the ancients to have been taken up from the earth, and raiſed to heaven.

GANNAPAREIRE, in *Botany*, a name by which ſome authors have called the tree which produces the famous Jeſuits bark. See CORTEX *Peruvianus*.

GANNET, in *Ornithology*, the name uſed in Cornwall, and ſome other parts of England, for the *Pelecanus baſſanus* of Linnæus, or the *Anſer Baſſanus* of Gooſe. Mr. Ray ſuppoſed the Scottiſh *gannet* to be a ſpecies of large gull; and he was led into this miſtake by never having an opportunity of ſeeing the bird, except flying; and in the air it has the appearance of a gull. On this ſuppoſition he gave it the title of *naturalis*, a name borrowed from Ariſtotle, and which admirably expreſſes the rapid deſcent of this bird on its prey. Penn.

GANTLET, or GAUNTLET, a large, ſtrong glove, made to cover the arm, or hand, of a cavalier, armed at all points.

The word is derived of the French *gantelet*; and that from *gand* or *gant*, *glove*.

The *gauntlet* was of iron, and the fingers plated. The caſk and *gauntlets* were always borne in the ancient marches in ceremony. *Gauntlets* were not introduced till about the thirteenth century.

The *gauntlet* was frequently thrown, like the glove, by way of challenge.

GANTLET, in *Surgery*, is a kind of BANDAGE for the hand, being a ſwathe, four or five yards long, wherewith they wrap up the hand, and all the fingers, one after another.

GANTLOPE, a military puniſhment. See *Military* EXECUTION.

GANTLOPE, or GAUNTLOPE, vulgarly pronounced *gunlo*, is a puniſhment for felony, or ſome other heinous offence, in a ſhip of war. For this purpoſe, the whole ſhip's crew is diſpoſed in two *rows*, ſtanding face to face on both ſides of the deck, ſo as to form a lane, whereby to go forward on one ſide, and return aft on the other; each perſon being furniſhed with a ſmall twiſted cord, called

called a knittle, having two or three knots upon it. The delinquent is then stripped naked above the waist, and ordered to pass forward between the two rows of men, and aft on the other side a certain number of times, rarely exceeding three; during which every person gives him a stripe as he runs along. This punishment, which is called *running the gauntlet*, is seldom inflicted except for such crimes as will naturally excite a general antipathy among the seamen.

GANYMEDE, *Ganymedes*, a term lately come in use to express a catamite, or bardache. See SODOMY.

The expression takes its rise from a young beautiful Trojan shepherd, thus called, whom Jupiter ravished, or carried off, by his eagle, or rather by himself, under the figure of an eagle, as he was hunting upon mount Ida; and made him his cup-bearer, in the place of Hebe; who, having made a false step, and spilt her liquor, was turned out of that office.

Some say, that the Jupiter who ravished *Ganymede* was Tantalus, king of Phrygia; the eagle expressed the swiftness wherewith he was carried off.

The statue of *Ganymede* was transported from Greece to Rome, and set up in the temple of Peace; and to this Juvenal refers, when he says,

Nupter erim cupies formam Jovis, et Ganymedem hic fossis.

GAOL, a prison, or place of legal confinement.

The word is formed of the French *geole*; and that of the barbarous Latin *gaola*, *gaiola*, *gayola*, or *cage*; whence the Picards still call a bird-cage *gayole*. The gaoler, geolier, was called *gaiolarius*, and *custodiarius*. Scaliger derives the word *geoler* from *janitorius*. And some Latin authors call him *commentariensis*, because he keeps a register, or bill, of all those under his custody.

Every county hath two *gaols*; one for debtors, which may be any house where the sheriff pleases; the other for the peace and matters of the crown, which is the county *gaol*.

If a *gaol* be out of repair, insufficient, &c. the justices of the peace in the quarter sessions may agree with workmen for rebuilding, or repairing it; and by warrant under their hands and seals, order the sums agreed upon to be levied upon the several hundreds and divisions in the county, by a proportionate rate. 10 & 11 W. III. cap. 29. See PRISON-*breaking*.

GAOL *delivery*. See JUSTICE.

GAOLER, is the master of a prison; one that hath the custody of the place where prisoners are kept. Sheriffs must make such *gaolers* for whom they will answer: but if there is a default in the *gaoler*, action lies against him for an escape, &c. 2 Inst. 592. In common cases the sheriff or *gaoler* are chargeable at the discretion of the party; though the sheriff is most usually charged. Wood's Inst. 76.

By 8 and 9 W. III. cap. 27. marshal and warden taking any reward to connive at prisoners escape, forfeits 500*l.* and his said office, and is for ever after incapable of holding such office. The office of marshal of the king's bench, and warden of the Fleet shall be executed by those who have the inheritance of the said prisons, or their deputies, &c. By 3 Geo. I. cap. 15. no one shall purchase the office of *gaoler*, or any other office pertaining to the high sheriff, under pain of 500*l.*

Where a *gaol* is broken by thieves, the *gaoler* is answerable not; if it be broken by enemies. 3 Inst. 52. It is enacted by 22 & 23 Car. II. cap. 20. that the rates of fees and government of prisons be signed by the lord chief justices, &c. and hung up in every *gaol*, fairly written; and also, that felons and prisoners for debt shall not be lodged together. No fees shall be taken by *gaolers* of prisoners, but such as are allowed by law; and the judges, &c. are to settle the same; also the judges may determine petitions against the extortions of *gaolers*, bailiffs, &c. 2 Geo. II. cap. 22. 18 Geo. II. cap. 13.

The abuses of *gaolers* and sheriff's officers towards the unfortunate persons in their custody, are well restrained and guarded against by statute 32 Geo. II. cap. 28.

Gaolers are not justified by law in fettering a prisoner, unless he is unruly, or has attempted an escape. 2 Inst. 381. 3 Inst. 34. The humane language of our ancient lawgivers is, *Custodes carceris sibi commissorum non augeant, nec vos torqueant; sed unum vinculum remota, potiatur quod exhibito, judicio debeat exequuntur.* Flet. lib. 1. cap. 26.

GAOL *fever*. See HOSPITAL *fever*.

GAONS, a certain order of Jewish doctors, who appeared in the East, after the closing of the Talmud. The word *gaons* signifies *excellent*, *sublime*; as in the divinity schools we formerly had irrefragable, sublime, resolute, angelic, and subtile doctors. The Gaons succeeded the Sebusæans, or Opiners, about the beginning of the 6th century. Chanan Messchia was the head, and first of the excellents: he restored the academy of Pandebita, which had been shut up for the space of thirty years.

GARAB, and ALGARAB, names given by Avicenna to the *ægilops*, or wild oat.

GARAGAY, in *Ornithology*, the name of a mysterious bird of Mexico, of the size of our kite; its head and the tips of its wings are white; it makes but short flights; it is very fond of the eggs of tortoises and crocodiles, and hunts the places where they have buried them in the sands.

GARATRONIUM, in *Natural History*, the name of a fossile body, commonly supposed the same with the botonites but very improperly; the only just account of it is that of Ferrante Imperato, who tells us, that it is a purple stone with variegations of a gold yellow, disposed in the manner of the veins of many sorts of marble; and that the Persians, and many of the eastern people, cut it into the handles of their sabres. It appears by this description to be a kind of jasper; and it is very improperly confounded with the botonites, a small stone fit only to be worn in rings.

GARB, a name given by the Moors to an African species of willow.

GARBE, in *Heraldry*, a representation of a sheaf of corn, or other grain; sometimes borne in coat-armour, in fessy summer, or the month of August; as the bunch of grapes denotes autumn.

GARBLER *of spices*, an officer of great antiquity in the city of London, who is empowered to enter any shop, warehouse, &c. to view and search drugs, &c. and to *garble* and cleanse them.

GARBLES, the dust, foil, or filth, severed from good spice, drugs, &c.

GARBLING of spices, drugs, &c. is the cleansing it from the dross and dust, mixed therewith, and severing the good from the bad.

The word comes from the Italian, *garbellare*, *to sift*.

GARBLING *of hemp and flax*, is the sorting or culling out the good from the bad.

GARBOARD-*strake*, in a *Ship*, is the first seam next to the keel.

GARBOARD-*plank*, in a *Ship*, the first plank fastened on the keel.

GARCINIA, in *Botany*. See MANGOUSTAN.

GARCON, or GARSOON, a French term, literally signifying a boy, or male child, any time before his marriage.

It is also applied to divers inferior officers, among us called *grooms*, *garçoniers*. Thus all the servants in the French king's chambers, wardrobe, &c. who do the lesser offices thereof under the proper officers, are called *garçons de la chambre*, *de la garderobbe*, &c.

GARD. See GUARD.

GARD, *ratisfement de*. See RATISEMENT.

GARD, *sauve de*. See SAUVE.

GARDANT, in *Heraldry*. See GUARDANT.

GARDECAUT, or GARD DU COEUR, is a watch, that which stops the fusee, when wound up, and for that end is driven up by the spring. Some call it *guard-coeur*; others, *guard du cœur*.

GARDEN, an inclosure or plot of ground, curiously cultivated, and furnished with variety of plants, flowers, fruits, &c.

Gardens are distinguished into *flower-gardens*, *fruit-gardens*, and *kitchen-gardens*: the first are for pleasure, and ornament, and, therefore, are placed in the most conspicuous parts; the two latter are for service, and, therefore, made in more obscure and retired places. These were formerly distinct, but they are now generally united; because they both require a good soil and exposure, and are equally placed out of the view of the house.

The principal things to be considered with respect to a *pleasure garden*, are the situation and exposure, the soil, water, prospect, and the method of designing or laying it out.

As to situation, it should be neither too high nor too low; for the winds in one of these extremes, and the damps and vermin in the other, are equally to be avoided. The sides of a hill are always the most eligible; and if the declivity be easy, and there are springs of water for supplying fountains, canals, and cascades, and for furnishing the adjacent valleys, the situation is peculiarly excellent. *Gardens* on level ground have their advantages, and are less expensive; but they want prospect, and several other agreeable circumstances that attend those on the sides of hills, not too steep. See EXPOSURE.

The second article, or the soil, is greatly to be regarded, as it is not possible to make a good *garden* when this is bad. Great expences may be incurred in meliorating the ground; and when this is done, the advantages of it will be lost in a little time; nay, where three feet of good earth have been laid on the surface of a whole *garden*, when the trees have been rooted enough to strike into the natural bottom, the whole plantation has been known to dwindle away. Places naturally producing heath and thistles are to be rejected; and where the trees are seen

to be flubbed, and flunted, it is an ill omen. When the grass grows well, and there is not less than three feet earth, *gardens* are sure to succeed. The ground must not be too stony, nor of all things a hard tough clay, which is most to be avoided of all soils for gardening. A deep, rich, black mould, is best for plants; sandy land is warm and forward, and good for flowers; cloddy land is cold and backward; but both may be corrected and improved by composts of different kinds, suited to their respective qualities. A third requisite is water, without which a *garden* must suffer extremely in droughts; besides the usefulness of it in forming ornamental canals, cascades, &c. To these may be added a very advantageous and pleasing, though not absolutely necessary thing, the prospect of a pleasant country. A *garden* planted in a low place, without any kind of prospect, will not only be disagreeable, but unwholesome. With regard to the method of designing and laying out a pleasure *garden*, it may be observed, that the area of a handsome *garden* may take up thirty or forty acres, not more, and the following rules should be observed in the disposition of it. There should always be a descent from the house to the *garden* of not fewer than three steps; this will render the house more dry and wholesome, and the prospect on entering the *garden* more extensive.

The first thing presenting itself to view in a pleasure *garden* should be an open lawn of grass, whose extent should be proportioned to that of the *garden*; in a large *garden* it should not be less than six or eight acres; but in smaller *gardens* the width of it should be considerably more than the front of the house, and its depth about one half more than the width. The figure of this lawn need not be regular; and if on the sides there are trees planted irregularly by way of open grove, some of which may be planted forwarder upon the lawn than others, whereby the regularity of the lawn will be broken, the *garden* will more resemble nature; for it should be always considered, that a *garden* is only a natural spot of ground dreſſed and ornamented.

The great art in laying out *gardens* is to adapt the several parts to the natural position of the ground, so as to have as little earth to remove as poſſible. Inſtead of levelling hills in order to form large terraces, ſtiff ſlopes and even parterres, or ſinking of hollows, and raiſing of hills, it is much better only to ſmooth and well turf the ſurface of the ground, which would have a more pleaſing effect, and be attended with a leſs expence of time and money. The *garden* ſhould be encompaſſed with a dry gravel walk, for the convenience of walking in dump weather. This walk may lead through the different plantations, winding about gently in an eaſy natural way, which is much preferable to long ſtrait walks. However, the turns ſhould be few and concealed, and ſo contrived as to lead into ſhade as ſoon as poſſible, and into ſome plantations of ſhrubs for ſhelter; for without ſhade and ſhelter no *garden* can be pleaſing. When the boundaries of the *garden* are fenced with walls or pales, they ſhould be hid by plantations of flowering ſhrubs, intermixed with laurels, and other evergreens. In ſituations where there is a good ſupply of water, it may be conducted through the garden in ſtreams or rivulets, and theſe, if they are formed with judgment, will have a better effect, and be much more ſalubrious and refreſhing than large ponds or canals of ſtagnant water, which render the air damp and unhealthy. If wilderneſſes are deſigned, they ſhould not be cut into ſtars, and other ridiculous figures, not formed into mazes or labyrinths, but the walks ſhould be noble and ſhaded by tall trees; and the ſpaces of the quarters planted with flowering ſhrubs and evergreens; and on the ſides of the walks may be ſcattered hardy ſorts of flowers, which will thrive with little care. Theſe wilderneſſes ſhould not be ſituated too near the houſe; but a communication and undereſtable may be made between them and the houſe by open groves. Buildings properly and ſparingly introduced, ſtatues and vaſes not placed too near each other, fountains and caſcades, &c. where a conſtant ſupply of water can be obtained, will greatly contribute to the ornament of a pleaſure *garden*. When the ground is naturally uneven, with gentle aſcents and declivities, theſe may be ſo managed as to be rendered great beauties; for this purpoſe the irregularities of the ground ſhould not be cut into regular ſtiff ſlopes and amphitheatres, but be properly planted with clumps of trees or ſhrubs, and the ſloping ſides ſmoothed and left in their natural poſition.

In forming a new *garden*, or altering the diſpoſition of an old one, great care ſhould be taken to preſerve all the good trees, wherever they can be rendered either uſeful or ornamental: the trees and ſhrubs that are introduced ſhould alſo be adapted to the ſituation and ſoil of the *garden*, and be allowed ſufficient room. Before a *garden* is planned out, it ſhould be conſidered what it will be in twenty or thirty years time, when the trees and ſhrubs are grown up and ſpread; and the general diſtribution of the parts of a *garden* ſhould be regulated by this proſpect, as well as by the ſituation of the ground. The great art of deſigning is to adapt the plan to the ſituation, to make the moſt of the inequalities of the ground, to proportion the number and ſorts of trees and ſhrubs to each part of the *garden*, and to ſhut out, from the view of it, no objects that either are or may be made ornamental. Miller.

The chief furniture of pleaſure *gardens* are, parterres, viſtas, glades, groves, compartiments, quincunxes, verdant halls, arbour-work, mazes, labyrinths, fountains, cabinets, caſcades, canals, terraces, &c. See each under its proper article.

GARNEN, *kitchen*. There are certain general rules always to be obſerved in making a *kitchen-garden*, which will render it much cheaper and more convenient than it uſually is at a venture, without the conſideration of them. It ſhould always be placed behind a houſe, that it may be both ſheltered and kept out of ſight, and always ſhould be as near as may be to the ſtables, that the dung may be ready, and coſt no great labour nor expence in carriage. A ſquare or oblong is the beſt figure for the ground; but this is not neceſſary, ſince all irregularities may be hid by the quarters. The ſoil muſt neither be very wet, nor very dry, nor too ſtiff; and if there are any ſtrings to any part of the ground, they are by no means to be levelled, as they will be of great uſe for different crops of ſeveral ſhapes. This *garden* muſt be fully expoſed to the ſun, and by no means overſhadowed by trees. See EXPOSURE. The quantity of ground is to be proportioned to the ſize of the family which it is to ſupply; for a ſmall one, an acre of ground will be enough, and there ſeldom requires more than three or four acres. It ſhould be walled all round with walls twelve feet high for the reception of fruit-trees, and the ground, when the ſoil is ſtrong and ſtiff, ſhould be ploughed or dug up three or four times before any thing is planted in it; and if it be thrown up in ridges to receive the froſt in winter, this will be of great ſervice to meliorate and looſen its parts.

In this caſe if the walls be manured with ſea-coal aſhes, the cleanings of the ſtreets of large towns, or ſea ſand, as alſo with rotten wood, and decayed and putrefied vegetables. On the contrary, if it be light and warm, it muſt be manured with rotten neat's dung; and if horſe-DUNG be uſed, it muſt be always very well rotted firſt.

The ſoil muſt be at leaſt two feet deep, and there muſt be a ſupply of water, which, if it can be contrived in baſons, or reſervoirs, will be very convenient and advantageous.

In the planting a fruit or *kitchen-garden*, if the ſoil be a hungry gravel, or ſand, Mr. Switzer directs the holes where the trees are to be planted, to be dug two feet deep, and three or four over, and filled with rotten horſe-dung mixed with rich mould.

As ſoon as the walls are built, the firſt thing to be done is the laying out of the borders under them, which ſhould be at leaſt eight or ten feet broad; and on thoſe which are expoſed to the ſouth, the early crops are to be planted, and the latter on thoſe to the north.

The trees being taken out of the nurſery, the biggeſt roots are to be ſhortened to about ſix inches; all the ſmall fibres to be taken off, and the head to be pruned, ſo as not to leave above four branches; and thoſe not above ſix inches long.

The wall trees are to be placed as far from the wall as may be, that there may be the more room for the roots to ſpread; then, filling up the whole with mould, there remains nothing but to ſecure the roots from the winter's froſt, by covering the ſpot with ſtraw, fern, dung, &c. and in ſummer from the ſun by ſand and pebble ſtones.

For trees planted in borders the common practice is to make a trench by the wall-ſide, two feet broad, and as many deep; this trench they fill with old dung, mixed with earth, lightly laid, near as high as the borders are intended to be, and then trodden down to half the height. In the places where the trees are intended to be, it is prudent to plant the trees ſhallow, and to raiſe the earth about them; eſpecially in a wet, clayey ſoil. See FRUIT-*trees* and PLANT-ING.

It is an obſervation of ſome importance, that wall trees and fruits thrive beſt when the walks that run parallel to them are gravel; more of the rays of the ſun being thereby reflected to them, than if they were graſs. Adde, that no ſort of tall trees are to be ſuffered to grow in any of the oppoſite borders, or intermediate ſpaces, ſo that their ſhade might reach to the ſouth-eaſt, or ſouth-weſt walls. The places near the walls are moſt advantageouſly filled with DWARF-*trees*.

No large or deep-rooting plants ſhould ever be ſet near

the roots of the wall-fruit trees, but the beans and peas, required to be early, ſhould be planted in the other parts of the *garden*, and ſheltered by moveable reed hedges, which will ſcreen and forward them as well as the walls. The next thing to be done, is the laying out the ground into quarters. Theſe ſhould never be too ſmall, but in a little *garden*, it is better to have only a few of them. They muſt be ſurrounded with ESPALIERS of fruit-trees, and have walks tufted between them, which, in a ſmall *garden*, ought to be ſix feet wide; in a large one, ten; and on each ſide the walk, there ſhould be allowed a border of three or four feet broad, between its edge and the eſpaliers. On theſe borders, ſmall fallading, or any thing that does not remain long, nor roor deep, is proper to be ſown. If the walks are covered with lime-rubbiſh or ſand, inſtead of being turfed, it will be an advantage to the fruit in the eſpaliers, though it takes off from the beauty of the *garden*. The beſt figure for the quarters is either a ſquare, or an oblong; but when the nature of the ground does not admit this, they may be triangular, or of any other form. The ground in theſe quarters ſhould never be ſown, or occupied by the ſame crop, for two years together; and when any part of the ground is not uſed, it ſhould be treached up in ridges, to receive the better the benefit of the dews and froſt.

In one of the quarters, which is neareſt the ſtables, and is moſt defended from bad weather, ſhould be the beds for cucumbers, melons, and other productions of the hot-bed; and it is a very good method to ſurround that part with a reed hedge, which both ſhelters and hides the beds from ſight. The ſquare ſhould always be large enough for the beds of two years.

The moſt important points of culture and management are the well digging and manuring the ſoil, and the giving a proper diſtance to each plant. The quarters and dunghills are both alſo to be kept clear of weeds; for if they are ſuffered to ſcatter their ſeeds on the dunghills, it is vain to root them out of the *garden*, as they will be continually renewed from thence. Miller's Gardeners Dict.

Robbing *gardens* and orchards of fruit growing in them, ſtealing underwoods and hedges, and ſtealing or deſtroying any turnips, or the roots of madder, when growing, are puniſhable criminally, by whipping, ſmall fines, impriſonment, and ſatisfaction to the party wronged, according to the nature of the offence, by the ſtatutes 43 Eliz. cap. 7. 15 Car. II. cap. 2. 23 Geo. II. cap. 26. and 31 Geo. II. cap. 35. And by ſtat. 6 Geo. III. cap. 36. and cap. 48. the ſtealing by night of any trees, or of any roots, ſhrubs, or plants to the value of 5l. is made felony in the principal aiders and abbettors, and in the purchaſers, knowing the ſame to be ſtolen; and the ſtealing of any timber trees, as oak, beech, chefnut, walnut, aſh, elm, cedar, fir, aſp, lime, ſycamore, and birch, and of any root, ſhrub, or plant, by day or night, is liable to pecuniary penalties for the two firſt offences, and for the third is a felony, liable to tranſportation for ſeven years.

GARDENS, *pendant*, or *hanging*. See PENSILES *horti*.

GARDENIA, *Cape jaſmine*, in *Botany*, a genus of the *pentandria monogynia* claſs: the ſtyle is elevated, and compoſed of two lobes; the calyx is divided into vertical ſegments, and the fruit is a polyſpermous berry. There is only one ſpecies.

GARDENING, *Horticulture*, the art of cultivating a *garden*.

Gardening has, in all ages, been eſteemed an employment worthy the greateſt heroes and philoſophers: the emperor Dioclefian, at Salona; and Epicurus and Metrodorus, at Athens, have ennobled the art beyond all encomium.

Goetzius, ſuperintendant of Lubeck, printed a diſſertation in 1706, intitled ΚΗΠΟΤΑΦΙΟΓΡΑΦΙΑ, ſeu de Eruditis Hortorum cultoribus, of the learned men who have loved and cultivated gardens: among which number he ranks Adam Gregory, Nazianzen, St. Auguſtine, Pliny, and Cicero; nor ſhould he have forgot the elder Cato, Democritus, Plato, and his academy.

The ſieur le Noſtre firſt carried *gardening* to any thing of perfection; M. la Quintinie has gone yet farther; nor have our own countrymen been wanting to its improvement; as London, Wiſe, Bradley, Laurence, Fairchild, Miller, Brown, &c.

M. Fatio has lately applied mathematical reaſoning to *gardening*; and ſhewn how to make the beſt uſe of the ſun's rays in gardens.

The principal operations in *gardening* are planting, tranſplanting, engrafting, inoculating, pruning, ſowing, &c. all which ſee under their proper articles.

Other particulars relating to the art of *gardening*, ſee under PINCHING, VARIEGATION, NURSERY, SEED, GREEN-HOUSE, HOT-BED, FRUIT-TREE, DWARF, SALLET, &c.

GARDENING, in *Falconry*. To *garden a hawk*, is to put her on a turf of graſs, to cheat her.

Some alſo uſe the ſame phraſe for the giving her an airing, or letting her fly at large.

GARDROBE. See WARD-ROBE.

GARDEYN. See GUARDIAN.

GARDIAN. See GUARDIAN.

GARDON, in *Ichthyology*, the name of a fiſh of the roach kind, ſuppoſed by many not to differ in any thing eſſential from the common roach of the Engliſh rivers; ſome authors call it the *gardon* SARGUS, and cephalus; others LEUCISCUS.

GARDUS, in *Ichthyology*, a name given by ſome writers on fiſhes to that kind of cyprinus, called by Geſner and others the fargus. See GARDON and CYPRINUS.

GARE, in our *Old Writers*, a coarſe wool, full of ſtaring hairs, ſuch as grow about the ſhanks of ſheep. 31 Edw. III. cap. 8.

GAR-FISH. See ESOX and ACUS.

GARGANEY, in *Ornithology*, *anas querquedula* of Linnæus, the name of a freſh-water fowl of the duck kind; it is ſmaller than the teal, but very like it in ſhape. Its beak, legs, and feet, are of a deep lead colour; the upper part of the head is duſky, but it has on each ſide a white ſtreak drawn from the eyes to the back part of the head; the throat and lower part of the neck are variegated with a white and reddiſh brown; juſt under the beak it has a black ſpot; the breaſt is beautifully variegated with tranſverſe undulated lines of black, and a duſky brown; the belly is white or yellowiſh. The female is ſmaller than the male, and has not the bright colours about the head, which are ſo beautiful in that. It has an obſcure white mark over the eye, and the reſt of the plumage is of a brownith aſh colour. Theſe birds are in many places called the ſummer teal.

GARGARISM, GARGLE, in *Medicine*, a liquid form of remedy, for diſorders in the mouth, gums, throat, &c.

The word is Greek, γαργαρισμα, formed of γαργαριζειν, *colluere*, to waſh, or the Hebrew *gargara*, the throat. *Gargariſms* are compoſed of honey, ſalt, ſyrups, ſpirits, vinegar, waters, and decoctions; and produce their effects, by cleanſing, lubricating, &c. the parts.

Gargles are peculiarly uſeful in fevers and ſore throats; and they have this advantage above many other medicines, that they are eaſily procured and prepared: an uſeful *gargle* for ſoftening and cleaning the mouth may be made with a little barley water and honey, acidulated with vinegar. *Gargles* bear different appellations according to the uſes to which they are applied. An *attenuating gargle*, made by mixing ſix ounces of water, with one ounce of honey and a dram and a half of nitre, or by adding an ounce of honey and half an ounce of ſpirit of ſal ammoniac to the emollient *gargle*, may be uſed in the inflammatory quinſey or in fevers, for cleaning the tongue and fauces. A good *gargle* for this purpoſe may be made with ſtrong ſage tea, ſweetened with honey and ſharpened with vinegar. The *common gargle*, made by mixing ſix ounces of roſe-water with half an ounce of ſyrup of clove July-flowers acidulated with ſpirit of vitriol, cleanſes the tongue and fauces, and ſerves alſo for a gentle repellent. The *detergent gargle*, prepared by mixing a plat of the emollient *gargle* with an ounce of tincture of myrrh and two ounces of honey, ſerves to cleanſe exulcerations and to promote the excretion of tough viſcid ſaliva. The *emollient gargle*, made by boiling an ounce of marſhmallow roots, and two or three figs in a quart of water till near one half of it be conſumed, and ſtraining out the liquor, is beneficial in fevers, when the tongue and fauces are rough and parched, to ſoften theſe parts and promote the diſcharge of the ſaliva. Sir John Pringle recommends a decoction of figs in milk and water, with the addition of ſal ammoniac, as an uſeful *gargle* in the inflammatory quinſey, or ſtrangulation of the fauces.

GARGET, a diſeaſe of cattle, conſiſting in a ſwelling of the throat, and the neighbouring parts; to prevent which, bleeding in the ſpring is recommended.

GARGIL, a diſtemper in geeſe, which by ſtopping the head frequently proves mortal. Three or four cloves of garlic, beaten in a mortar, with ſweet butter, and made into little balls, and given the creature faſting, are the ordinary cure.

GARHANA, in *Ichthyology*, a name by which ſome have called a large Braſilian fiſh, of the ſhape of our carp, more uſually known among authors, by its Braſilian name ACARAAYA.

GARICON, in the *Materia Medica*, a name given by the Arabian writers to the drug called agaric by the ancients.

The Arabians have ſaid nothing of this drug, but what they have tranſcribed from the Greek of Diſcorides and others; it is certain, however, from the concurrent teſti-

mony of all the ancients, as to the form, nature, and virtues of AGARIC, that theirs was not the same substance which we call by this name.

The ancients knew two kinds of what they called agaric; they distinguished these by the common terms of male and female; the male was a root resembling the silphium of a cubit long, and of an inch or two in diameter; the female was the corrupted wood of certain trees, particularly of the *cedar*, and other odoriferous woods.

Pliny makes it indeed the decayed wood of the oak, which shines like fire in the dark, and calls it the fungus, but this was not the agaric of the Greeks.

The female agaric, or the decayed wood of the cedar, was what they gave as an antidote and cordial; the male, or as others called it, the black agaric, was poisonous. Dioscorides places it among the poisonous roots, and Aricenna condemns it, as hard and unfit for internal use; the other, or female agaric, being soft, friable, and tender. When it was thus in a great degree, however, it was condemned by the more accurate writers; and Dioscorides, in particular, condemns the agarics of Cilicia and Galatia as too friable, and of no value: so that they seemed to fix upon a proper stage in the decay, as the necessary qualification of good agaric.

GARIDELLA, so named by Tournefort in honour of Dr. Garidel, professor of physic at Aix in Provence, in *Botany*, a genus of the *decandria trigynia* class. Its characters are these: the flower hath no petals, but five oblong equal nectariums occupy their place, which are bilabiate. It hath eight or ten awl-shaped stamina, which are shorter than the empalement. In the centre are situated three compressed germina, which become three oblong compressed capsules with two valves including several small seeds. We know but one *species* of this *genus*.

GARLAND, an ornament for the head, made in manner of a crown or chaplet.

The word is formed of the French *guirlande*, and that of the barbarous Latin *garlanda*, or Italian *ghirlanda*. Menage traces its origin from *gyrus*, through *gyrulus*, to *gyrulare*, *gyrlandum*, *ghirlandum*; and at length *ghirlanda*, and *guirlande*: so that *guirlande*, and *garland*, are descended, in the sixth or seventh degree, from *gyrus*. Hicks rejects this derivation, and brings the word from *gardel banda*; which, in the northern languages, signify, *a noseguy artfully wrought with the hand*.

Garlands are a sort of chaplets, made of flowers, feathers, or even of precious stones, but especially of flowers; to which the word, in our language, is more immediately appropriated. Janus passes in antiquity for the inventor of *garlands*. Athen. Dipnof. lib. xv.

GARLANDS also denote ornaments of flowers, fruits and leaves intermixed; anciently much used at the gates of temples, where feasts, or solemn rejoicings, were held; or at any other places where marks of public joy and gaiety were desired; as at triumphal arches, tournaments, &c. *Garlands*, or festoons, were also put on the heads of victims, in the ancient heathen sacrifices. St. Paulinus, in his poem on St. Felix, does not forget the *garlands*, and crowns of flowers placed at the door of the church, and on the tomb of that saint.

The Italians have a sort of artificers called *festaroli*, whose office is, to make *garlands*, or festoons, and other decorations for feasts.

GARLAND, in a *Ship*, denotes a collar of ropes, wound about the head of the main-mast, to keep the shrouds from galling.

GARLAND is also a sort of net, whose opening is extended by a wooden hoop of sufficient size to admit a bowl or platter within it. It is used by the sailors as a locker or cupboard to contain their provisions, being hung up to the deck, within the birth, where they commonly mess between decks.

GARLAND, *Shot*, in a piece of timber nailed horizontally along the ship's side from one gun-port to another, and used to contain the round shot ready for charging the great guns in battle. For this purpose it is furnished with several semi-globular cavities, corresponding to the size of the cannon balls contained in it.

GARLICK, *Allium*, in *Botany*, a genus of the *hexandria monogynia* class. Its characters are these: the flowers are included in one common spatha, and are composed of six oblong erect petals, and six awl-shaped stamina, of the length of the petals, and crowned with oblong summits; the germen, which supports a single style, crowned by an acute stigma, becomes a three-cornered capsule, opening into three parts, having three cells, filled with roundish seeds. Miller enumerates nineteen and Linnæus thirty-eight species.

The common *garlick* and rocambole are easily propagated by planting the cloves, or small bulbs, in the spring, in beds, about four or five inches distant from each other, keeping them clear from weeds. About the beginning of June, the leaves of the first sort should be tied in knots to prevent their spindling, or running to seed which will greatly enlarge the bulb. In the middle of July, the leaves will begin to wither and decay, at which time they should be taken out of the ground, and hung up in a dry room, to prevent their rotting, and may be thus preserved for winter use. The roots of the second sort may be left in the ground till the leaves are decayed, and their bulbs may then be taken up and dried.

Garlick is an extremely active and penetrating medicine. It is of the number of those roots which ought always to be used fresh and full of juice, not dried; some esteem it the greatest of all alexipharmics. To warm and stimulate the solids, attenuate thick humours, and resist putrefaction are its primary virtues: on this account it is improper in hot bilious constitutions; but in cold, sluggish, phlegmatic habits, it proves a salutary and powerful corroborant, expectorant, diuretic, and sudorific. The German physicians frequently eat a clove of *garlic* in their mouths, when they visit patients in malignant fevers: with us it is more in use among country people, than in the shops. They give a decoction of *garlick* in milk, as a remedy for worms, and also in the colic, and in suppressions of urine. Its most constant use, however, is in asthmas, and catarrhous disorders of the breast, in which it promotes expectoration. It has likewise been found serviceable in the beginning of dropsies, and for preventing a new accumulation of water, after evacuation. Sydenham relates, that he has known the dropsy cured by the use of *garlick* alone.

Whatever may be the virtues of *garlick* it ought to be used in small doses, and that not too frequently, because, if long continued, it is apt to heat and inflame the viscera.

Garlick is sometimes employed externally, in unguents and lotions, as an antiseptic and discutient; and is frequently an ingredient in the stimulating epithems, applied to the soles of the feet, in the low stage of acute distempers, for raising the pulse, and relieving the head; and it is much commended by Sydenham for this purpose. The roots lose considerably of their weight by drying; so that six grains dry may be looked upon as equivalent to fifteen grains of the fresh root. The fresh root yields, on expression, about a fourth of its quantity of a very viscid glutinous juice; and both the fresh and dry root communicate their virtue to water by warm infusion. A quart of water poured boiling hot on a pound of the fresh root sliced, with a proper quantity of sugar, makes the syrup of *garlick* of the shops. The oxymel of *garlick* is prepared by infusing an ounce and a half of the fresh root in half a pint of vinegar, and dissolving in the strained liquor, by the heat of a water-bath, ten ounces of clarified honey. The ill smell of the *garlick* may be in some degree prevented by boiling two drams of caraway, and the same quantity of sweet fennel seeds bruised in the vinegar, before the *garlick* is put in. The *garlick* should never be boiled, either with vinegar or watery liquors, because the virtues of this root, residing in an essential oil, are exhaled with the steam. Rectified spirit of wine, digested on dry *garlic* root, extracts its virtues more readily and perfectly than either water or vinegar. Lewis's Mat. Med.

GARLIC, *wild*, a name given to a species of ONION.

GARLICK, *great*. See CRATEVA.

GARNET, in *Natural History*. See GRANATE.

GARNET, in a *Ship*, is a tackle having a pendant coming from the head of the main-mast, with a block throughly seized to the main-stay, just over the hatch-way; in which block is reeved the runner, which hath a hook at one end, in which are hitched the slings; and at the other end is a double block, in which the fall of the runner is reeved; so that by its means any goods, or casks, that are not over heavy, may be haled and hoised into, or out of the ship: when this *garnet* is not used, it is fastened along by the stay at the bottom of it.

GARNET, *clew*. See CLEW-*garnet*.

GARNISH, in some ancient writings and statutes. To *garnish* the heir, signifies to warn the heir. 27 Eliz. cap. 3.

GARNISHEE, in *Law*, the party in whose hands money is attached within the liberties of the cities of *London*; so called in the sheriff's court, because he has had *garnishment*, or warning, not to pay the money, but to appear and answer to the plaintiff-creditor's suit.

GARNISHING is popularly used for the furniture, adornage, or ornament, necessary for the using or adorning any thing.

The word is French, formed of the verb *garnir*, to furnish, or fit out.

The *garnishing* of a dish consists of certain things which accompany it, either as a part and ingredient thereof; in which sense pickles, mushrooms, oysters, &c. are *garnish-*

garnishing: or as a circumſtance, or ornament; as when leaves, flowers, roots, &c. are laid about a ſervice to amuſe the eye.

The ſame word is uſed for the finer herbs, fruits, &c. laid about a ſallet: *garniſhings* are of lemon, piſtachos, pomegranate, yolks of hard eggs, artichoke-bottoms, capers, truffles, ſweetbread, &c.

GARNISHMENT, in *Law*, denotes a warning given any one to appear, for the better furniſhing of the cauſe, and court. Thus, if one be ſued for the detinue of certain charters; and ſays, they were delivered to him, not only by the plaintiff, but by J. S. alſo; and therefore prays, that J. S. may be warned to plead with the plaintiff, whether the conditions are performed, or no. In this petition he is ſaid to pray *garniſhment*; which may be interpreted, a warning to J. S. to provide himſelf for a defence; or elſe a furniſhing the court with all parties to the action, whereby it may thoroughly determine the cauſe.

GAROSMUS, in *Botany*, a name uſed by ſome authors for the atriplex olida, or ſtinking orach, a very ſtinking low plant common on dunghills.

GARRISON, in the *Art of War*, a body of forces diſpoſed in a fortreſs, to defend it againſt the enemy, or to keep the inhabitants in ſubjection, or even to be ſubſiſted during the winter ſeaſon.

Du-Cange derives the word from the corrupt Latin *garniſa*: which the latter writers uſed to ſignify all manner of munition, arms, victuals, &c. neceſſary for the defence of a place, and the ſuſtaining of a ſiege.

Garriſon, and *winter quarters*, are ſometimes uſed indifferently for the ſame thing; and ſometimes they denote different things.

In the latter caſe, a *garriſon* is a place wherein forces are maintained to receive it, and where they keep regular guards; as, a frontier town, a citadel, caſtle, tower, &c. The *garriſon* ſhould always be ſtronger than the townſmen.

Winter quarters ſignify a place where a number of forces are laid up in the winter ſeaſon, without keeping the regular guard. The ſoldiers, therefore, like better to be in winter quarters than in *garriſon*.

GARRISON *carriages* are thoſe on which all ſorts of *garriſon* pieces are mounted. See CARRIAGE.

GARRISON *guns* conſiſt of 42, 32, 24, 18, 12, 9, and 6 pounders; and they are made either of braſs or iron. The following table exhibits their dimenſions.

Braſs *Garriſon* Pieces.				Iron *Garriſon* Pieces.			
Caliber	Length	Weight		Caliber	Length	Weight	
	f. i.	c. qr. lb.			f. i.	c. qr. lb.	
42	10 0	64 0 0		32	9 8	56 0 0	
32	9 2	49 2 18		24	9 8	48 0 0	
24	8 4	37 0 0		18	9 0	36 0 0	
18	7 6	27 3 0		12	7 8	24 0 0	
12	6 7	18 2 0		9	7 0	18 0 0

See GUN.

GARRULUS *Bohemicus*, the *Bohemian magpye*, a name given by ſome to the bird more uſually called AMPELIS, from its love of grapes.

GARRULUS *Argentoratenſis*, in *Ornithology*, the name given by authors to the ſpecies of magpie commonly called the ROLLER, a very beautiful variegated bird, brought to market in Italy, and ſome other places.

GARTER, *vaginula*, a ligature to keep up the ſtockings: it is alſo particularly uſed for the badge or cognizance of a noble order of knights, hence denominated the *Order of the* GARTER, a military order, next in dignity after the nobility, inſtituted by king Edward III. in 1344, under the title of the *ſovereign* and *knights-companions of the moſt noble order of the* Garter.

This order conſiſts of twenty-ſix knights, or companions, generally peers or princes; whereof the king of England is the ſovereign, or chief.

They wear a *garter*, ſet with pearls and precious ſtones on the left leg, between the knee and calf, with this motto; *honi ſoit qui mal y penſe*, q. d. *ſhame to him that thinks evil hereof*: and they bear this motto ſurrounding their arms. The meaning of which motto is ſaid to be, that king Edward having laid claim to the kingdom of France, retorted ſhame and defiance upon him that ſhould dare to think amiſs of the juſt enterprize he had undertaken for recovering his lawful right to that crown; and that the bravery of thoſe knights whom he had elected into this order was ſuch as would enable him to maintain the quarrel againſt thoſe who thought ill of it.

They are a college or corporation, having a great and little ſeal; their officers are a prelate, chancellor, regiſter, king at arms, and uſher.

Beſides which, they have a dean and twelve canons, with petty canons, vergers, and twenty-ſix penſioners, or poor knights.

The prelate is the head; and the office is veſted in the biſhop of Winchester: next to him is the chancellor, which office is veſted in the biſhop of Saliſbury, who keeps the ſeals. All theſe officers, except the prelate, have fees and penſions.

The order is under the patronage and protection of St. George of Cappadocia, the tutelar St. of this kingdom. Their college is held at the caſtle of Windſor, within the chapel of St. George, and the chapter-houſe, erected by the founder for that purpoſe. Their robes, &c. are the *garter*, decked with gold and gems, and a buckle of gold, to be worn daily; and at feaſts and ſolemnities, a fur-coat, mantle, high velvet cap, collar of SS's, compoſed of roſes enamelled, &c.

The mantle is the chief of thoſe veſtments made uſe of on ſolemn occaſions. Its colour is by the ſtatutes appointed to be blue. The length of the train of the mantle only diſtinguiſhes the ſovereign from the knights-companions; to the collar of the mantle is fixed a pair of long ſtrings, anciently wove with blue ſilk only, but now twiſted round, and made of Venice gold and ſilk, of the colour of the robe, with knobs or buttons, and taſſels at the end. The left ſhoulder of the mantle has from the inſtitution been adorned with a large *garter*, with the device HONI SOIT, &c. within this is the croſs of the order, which was ordained to be worn at all times by king Charles I. At length the ſtar was introduced, which is a fort of croſs, irradiated with beams of ſilver. The collar is appointed to be compoſed of pieces of gold in faſhion of *garters*, with the ground enamelled blue, and the motto gold.

When they wear not their robes, they are to have a ſilver ſtar on the left ſide; and they commonly bear the picture of St. George, enamelled on gold, and beſet with diamonds at the end of a blue ribbon, croſſing the body from the left ſhoulder. They are not to appear abroad without the *garter*, on penalty of 6*l.* 8*d.* paid to the regiſter.

The manner of electing a knight-companion into this moſt noble order, and the ceremonies of inveſtiture, are as follow. When the ſovereign deſigns to elect a companion of the *garter*, the chancellor of the order draws up the letters, which, paſſing both under the ſovereign's ſign manual, and ſignet of the order, are ſent to the perſon by *Garter* principal king at arms; and are to this effect: "We, with the companions of our moſt noble order of "the *garter*, aſſembled in chapter, holden this preſent "day at our caſtle at Windſor, conſidering the virtuous "fidelity you have ſhewn, and the honourable exploits "you have done in our ſervice, by vindicating and maintaining our rights, &c. have elected and choſen you "one of the companions of our order. Therefore, we "require you to make your ſpeedy repair unto us, to "receive the enſigns thereof, and be ready for your inſtallation upon the day of this preſent month," &c. The *garter*, which is of blue velvet, bordered with fine gold wire, having commonly the letters of the motto of the ſame, is, at the time of election, buckled on the left leg by two of the ſenior companions, who receive it from the ſovereign, to whom it was preſented on a velvet cuſhion by *Garter* king at arms, with the uſual reverence, whilſt the chancellor reads the following admoniſhion enjoined by the ſtatutes: "To the honour of God omni-"potent, and in memorial of the bleſſed martyr St. "George, tie about thy leg, for thy renown, this noble "*garter*; wear it as the ſymbol of the moſt illuſtrious "order, never to be forgotten or laid aſide; that thereby "thou mayeſt be admoniſhed to be courageous, and "having undertaken a juſt war in which thou ſhalt be "engaged, thou mayeſt ſtand firm, valiantly fight, and "ſucceſſively conquer." The princely *garter* being thus buckled on, and the words of its ſignification pronounced, the knight elect is brought before the ſovereign, who puts about his neck, kneeling, a ſky-coloured ribband, to which is appendant, wrought in gold within the *garter*, the image of St. George on horſeback, with his ſword drawn, encountering with the dragon. In the mean time the chancellor reads the following admoniſtion: "Wear this ribband about thy neck, adorned with "the image of the bleſſed martyr and ſoldier of Chriſt "St. George, by whoſe inviſtation provoked, thou mayeſt "ſo overpaſs both proſperous and adverſe adventures, "that having ſtoutly vanquiſhed thine enemies both of "body and ſoul, thou mayeſt not only receive the praiſe "of this tranſient combat, but be crowned with the "palm of eternal glory." Then the knight elected kiſſes his ſovereign's hand, thanks his majeſty for the

great

great honour done him, rises up and salutes all the companions severally, who return their congratulations.

The order of the *Garter* appears the most ancient and noble lay-order in the world. It is prior to the French order of St. Michael, by 50 years; to that of the golden Fleece, by 80 years; to that of St. Andrew, by 190 years; and to that of the Elephant, by 209 years.

Since its institution, there have been eight emperors and twenty-seven or twenty-eight foreign kings, beside numerous sovereign princes, enrolled as companions thereof.

Its origin is somewhat differently related: the common account is, that it was erected in honour of a *garter* of the countess of Salisbury, which she dropped in dancing and which king Edward picked up; but our best antiquaries set this aside as fabulous.

Camden, Fern, &c. take it to have been instituted on occasion of the victory obtained over the French at the battle of Cressy; that prince, say some historians, ordered his *garter* to be displayed, as a signal of battle; in commemoration whereof, he made a *garter* the principal ornament of the order erected in memory of this signal victory, and a symbol of the indissoluble union of the knights.

Fa. Papebroche, in his analecta on St. George, in the third tome of the Acta Sanctorum, published by the Bollandists, has a dissertation on the *Order of the Garter*. This order, he observes, is no less known under the name of St. George than under that of *garter*, and that, tho' it was only instituted by king Edward III. yet it had been projected before him by king Richard I. in his expedition to the Holy-Land, if we may credit an author who wrote under Henry VIII. Papebroche adds, however, that he does not see what that author grounds his opinion on; and that, though the generality of writers fix the epocha of this institution to the year 1350, he rather chuses, with Froissard, to refer it to the year 1344, which agrees better with the history of that prince, where we read, that he called an extraordinary assembly of knights that year.

It appears from Rastel's Chronicle, lib. vi. quoted by Granger in the Supplement to his Biographical History, that this order was devised by Richard I. at the siege of the city of Acres, when he caused twenty-six knights, who firmly stood by him, to wear thongs of blue leather about their legs, and that it was perfected in the nineteenth year of Edward III.

In 1551, Edward VI. made some alterations in the ritual of this order: that prince composed it in Latin, the original whereof is still extant in his own hand-writing. He there ordained, that the order should no longer be called the order of St. George, but that of the *Garter*; and, instead of the George, hung at the collar, he substituted a cavalier, bearing a book on the point of his sword, with the word *probatio* graven on the sword, and *verbum Dei* on the book; with a buckle in the left-hand and the word *fides* thereon. Larrey.

For a farther account of the order of the *Garter*, see Camden, Athmole, Dawson, Leland, Polydore Virgil, Heylin, Legar, Glover, and Fauyn.

Erhard, Cellius, and the prince of Orange, adds Papebroche, have given descriptions of the ceremonies used at the installment of knights. A Cistercian monk, named Mendocius Belvaletus, has a treatise, intituled La Carretiere, or Speculum Anglicanum, since printed under the title of the Catechism of the Order of the *Garter*; wherein he explains all the allegories, real or pretended, of those ceremonies, with the moral significations thereof.

GARTER *principal king at arms*. This office was instituted by Henry V.

Garter, and *principal king at arms*, are two distinct offices united in one person: *Garter*'s employment is to attend the service of the order of the *garter*; for which he is allowed a mantle and badge, a house in Windsor-castle, and pensions both from the sovereign and knights, and, lastly, fees. He also carries the rod and sceptre at every feast of St. George, when the sovereign is present, and notifies the election of such as are new chosen; attends the solemnity of their installations, and takes care of placing their arms over their seats; and carries the *garter* to foreign kings and princes, for which service it has been usual to join him in commission with some peer, or other person of distinction.

Garter's oath relates only to services being performed within the order, and is taken in chapter before the sovereign and knights. His oath, as king at arms, is taken before the earl marshal.

GARTER is also a term in heraldry, signifying the moiety, or half of a bend.

GARTH. See FISHGARTH.

GARTH is used in some parts of England for a little backside or close. It is an ancient British word. *Gardd*, in that language, signifies *garden*, and is pronounced and written *garth*.

The word is also used for a dam or wear, &c.

GARTH-*men* is used in our statutes for those who catch fish by means of fish-*garths* or wears.

By statute it is ordained, that no fisher, nor garth-man, shall use any nets or engines to destroy the fry of fish, &c. 17 Ric. II. cap. 9. The word is supposed by some to be derived from the Scotch word *gart*, which signifies *forced*, or *compelled*; because fish are forced by the wear to pass in a loop, where they are taken.

GARUM, a word in very common use among the old writers on medicine, who expressed by it a pickle, in which fish had been preserved. The principal kind of fish they preserved in this manner was the mackarel.

The *garum* principally consisted of the juices of the fish and salt; but we find the old writers speaking of several kinds of it: one they called Spanish *garum*, from the place whence they had it; another kind from its colour was termed the black *garum*: this last kind seems to have been that called *faecidum* by the Latin poets, as if the faeces and remains of the fish were left among it, and by others *garum sanguineum*, from its being sometimes tinged with their blood to a reddish colour. The Romans sometimes called the Spanish kind, which was esteemed the best, *garum sociorum*; and Galen says, that the black *garum* was called *oxygarum*, but he only means by this, that it was used in the preparations called oxygara. It served to dilute them, and thence took the name of them to itself, by way of distinction from the Spanish, and other kinds, not used to this purpose. Pliny tells us, that *garum* was composed of all the offals of fish, of every kind, macerated in salt; it had its name, he says, from its being originally made of a fish, called by the Greeks *garos*, but in his time the best seems to have been made with the mackarel; but that there were several other kinds used both in food and medicine, some of which must have been made from scarce fish, for they were of great price. They were used in glysters, and externally applied in several kinds of cutaneous eruptions: the ancients had a great opinion of them in glysters, for removing the pain in the sciatica, and other like cases; and the coarser sorts were their common medicine for curing cattle of the scab, by making incisions in the skin, and laying over the part cloths wetted with it. See Strabo, lib. iii. 109. Plin. lib. xxxi. cap. 8.

The true way in which the ancients prepared their *garum*, which they so much valued as a delicacy at their tables, is unknown to us; but it appears that some kinds of *garum* had no fishy matter in them, from Aetius, who gives the following prescription of a liquor, which he calls by this name: take of common water thirty-one pints, of sea salt two pints, and of dried figs fifty; let these all macerate together, and afterwards be strained clear for use. All the *garums* were esteemed hot and drying by the ancients, and were sometimes given as laxatives before food. The modern writers understand the word *garum* in a much more limited sense, meaning no more by it than the brine or pickle in which herrings or anchovies are preserved.

GARYOPHYLLUS. See CLOVE-*tree*.

GAS, in *Chemistry*, derived, according to Junker, from the German *gaschen*, *a frothy ebullition*, and by Lavoisier, from the Dutch *ploegh*, or German *geist*, *spirit*, is a name given to the volatile invisible parts which escape from certain bodies, and which cannot be retained and collected, at least without great difficulty and mixture of other substances. The word is applied by Van Helmont to signify those elastic fluids which are invisible, and not condensable by cold; several of which he has described; such are the *gas ventosum*, or atmospherical air; *gas sylvestre*, or the fluid expelled during fermentations and effervescences, called by later authors, fixed, factitious, and fixable air; *gas pingue*, or the fluid extricated from inflammable substances during their analysis by heat; *gas flammeum*, or the fluid produced in the deflagration of nitre. He considers also, as so many kinds of *gas*, the noxious fluids which hover over the Grotto delle Cani in the kingdom of Naples, and at the bottom of mines and cellars, and that which arises in the burning of charcoal; the gas produced by the putrefaction of animal bodies; the matter which produces the plague; the *gas nitri*, or arterial spirit of life; and his celebrated ARCHEUS. See AIR, *fixable*, &c. and DAMP. See an excellent treatise on the various kinds of *gas*, by the translator of Macquer's Dict. of Chemistry, published as an appendix to the last edition of that valuable work, 1777: in which treatise the ingenious author maintains, that most of the known *gases* consist principally of acid and phlogiston.

GASCOIGN, or GASKOING, the hinder thigh of a horse, commencing from the flank, and reaching to the ply, or bending of the ham.

GASCOIGN, or *Lemeric's powder*, in *Medicine*, is formed of the compound powder of crab's claws one pound, of oriental bezoar prepared one ounce: this powder is made up into balls, called Gascoign balls, from the name of their inventor.

GASCONADE, a boast or vaunt of something very improbable.

The term has its rise from the Gascoons, or people of Gascony, in France, who, it seems, have been distinguished for bragging and rhodomontado.

GASKETS, on *ship-board*, the small cord used to fasten the sails to the yards when furled up.

GAST *board*. See GAZE HOUND.

GASTALDUS, or CASTALDUS, an officer anciently entertained in the courts of divers princes.

The word is also written *gastaldeus*, *gastaldio*, *gastaldatus*, *gwastaldus*, &c. Mezeri derives it from the Arabic *chastandar*, *purveyor of a house*; others from the German *gast*, and *halten*, *to retain travellers*.

The *gastaldus* was what in Italy and Spain is now called *major domo*, viz. the master and steward of a household.

The *gastaldius* was a comes, or count; which shews his office to have been very considerable.

In the laws of Italy, we sometimes also meet with *gastaldius* in the sense of a countier, and sometimes as an ecclesiastical officer; so that it is somewhere expressed to be simony to buy the function of *gastaldio*.

GASTEROSTEUS, in *Ichthyology*, the name of a genus of the acanthopterygious fishes, the characters of which according to Artedi, are these: the branchiostege membrane on each side contains three small and slender bones; the belly is almost all over covered with bony scales; the belly-fins have only two rays, the one of which is much larger than the other, and is prickly. The species of this fish are three. This is a genus of the *thoracici* of Linnæus, who enumerates eleven species, distinguished by the number of back-fins.

The name is of Greek origin, and is derived from the words γαστηρ, *the belly*, and οστεον, *a bone*; the greater part of the belly of this fish being fortified by bony plates. See STICKLE-*back*.

GASTREPIPLOICA, in *Anatomy*, a vein which opens into the trunk of the vena porta, formed of several branches, derived from the stomach and epiploon. Whence its name, from γαστηρ, *stomach*, and πτυαξ, *epiploon*.

GASTRIC, GASTRICUS, in *Anatomy*, is applied to divers veins, on account of their proceeding from the stomach or ventricle, which the Greeks call γαστηρ.

The *gastricus major*, or greater *gastric* vein, is inserted into the splenic vein; and the *minor*, or lesser *gastric*, into the trunk of the vena porta.

GASTRIC is also applied to two arteries; one of which, called the *gastrica dextra*, or *major*, proceeds from the hepatic artery, and passing behind the pylorus, runs along the right side of the great curvature of the stomach, at last ends in the *gastrica sinistra*, or *minor*, which is a branch of the *splenica*, and runs from the left to the right, along the left portion of the great curvature of the stomach.

GASTRIC *juice*, a name given by some authors to the proper juice of the stomach. This is a thin, pellucid, spumous, and saltish liquor, which continually distils from the glandulous kernels of the stomach, for the dissolution, mixture, and dilution of our food, and is of great service in digestion.

GASTRILOQUIUS, or GASTRILOQUUS, a person who speaks inwardly, or within his stomach, and whose voice seems to come from afar off; more usually called VENTRILOQUUS.

The term is formed of the Greek, γαστηρ, *belly*, *stomach*, and the Latin, *loqui*, *to speak*.

GASTROCNEMIUS, from γαστηρ, and κνημη, *the leg*, in *Anatomy*, a name common to two muscles, constituting the sura, or calf of the leg: the one called *externus*, and the other *internus*. See *Tab. Anat. (Myol.) fig.* 6, 11, 41.

GASTROCNEMIUS *externus*, called also *suralis externus*, and *gemellus*, has two distinct fleshy originations from the superior and hindermost part of each tubercle of the lower appendage of the thigh-bone, which in their descent, are each dilated into two small fleshy bellies, the innermost of which is thickest and largest, having each a different series of fleshy fibres, which at length uniting, make a broad, strong tendon; which, narrowing itself, joins the great tendon of the soleus, four fingers breadth above its insertion into the os calcis. See *Tab. Anat. (Myol.) fig.* 1. *n.* 66. *fig.* 2. *n.* 48.

When this muscle acts, the foot is said to be extended, or pulled backwards; which motion is very necessary in walking, running, leaping, or standing on tip-toe, &c. Whence it is, that those who walk much, or carry heavy burdens, and who wear low-heeled shoes, have their muscles larger than others.

GASTROCNEMIUS *internus*, or *soralis internus*, called also *soleus*, from its figure resembling a sole-fish, is placed under the external. Its outer fleshy part is covered with a transparent tendinous expansion, which makes it appear of a livid colour. See *Tab. Anat. (Myol.) fig.* 1. *n.* 63. *fig.* 2. *n.* 47.

It begins partly tendinous, chiefly from the hindermost part of the upper appendix of the fibula, and back part of the tibia, that is, below the insertion of the *subpoplitæus*: and increases to a large fleshy belly, composed of various orders of fleshy fibres, some of them underneath aptly expelling the figure of the top of a feather, whose stamina, being base tendinous, join with the great tendon, which is about a finger's breadth long, and inserted into the superior and hindermost part of the os calcis.

The foot, together with the toes, being, as it were, a lever to the whole body, ought therefore to be attended with muscles of great strength to extend it; which is the reason that these muscles so much exceed their antagonists.

GASTROLATER, of γαστηρ, and λατρευω, *a glutton*, or *belly-god*; *cujus deus venter est*.

GASTROMANCY, or GASTROMANTIA, a kind of divination, practised among the ancients, by means of words coming, or seeming to come, out of the belly.

The word is Greek γαστρομαντεια, compoled of γαστηρ, *belly*, and μαντεια, *divination*.

There is another kind of divination, called by the same name *gasteromancy*, which is performed by means of glasses, or other round, transparent vessels, within which certain figures appear by magic art. It is thus called, because the figures appear as in the belly of the vessels.

GASTROPHY, in *Surgery*, expresses the operation of the future, or sewing up wounds in the abdomen.

The word is derived from γαστηρ, *the belly*, or *abdomen*, and ραπη, *a future*.

This operation is generally much dreaded by the patient, and is unnecessary in several cases: 1. where the wound is only in the muscular part; and 2. where it is not very large, especially if it be made lengthways: for if the wound should penetrate into the cavity of the abdomen, and even let out a part of the omentum, or intestines; yet in cases where it is very small, as wounds generally are, which are made by puncture, or have happened lengthways; in these cases, upon returning the parts which are pushed out, stopping the wound with a soft tent, and securing all with a proper bandage, it may be healed without the help of the needle. Besides, in fat persons, this operation is very difficult; and it would be an act of great cruelty in a surgeon, to perform this operation upon a man, when he might be cured after an easier method.

But there are two cases in which this operation is absolutely necessary: the first is, where the wound is so large, that there is no possibility of retaining the intestines by any other method; for as the intestines are continually pushed forward in the act of inspiration, by the action of the diaphragm and the abdomen, the falling down of the intestines, in this case, is unavoidable; and therefore the operation is necessary; the other is in large transverse wounds of the abdomen, where the muscles are divided, but the peritoneum is not concerned.

In wounds of the ABDOMEN, the chief enquiry is, whether the omentum or intestines are let out: if none of these have burst through the wound, the lips of the wound must be kept as close together as possible with the hands, and the patient kept with his head lying downwards, till the wound is sufficiently secured from letting out the contents of the abdomen: but when the intestines are already fallen out, they must be returned with the greatest expedition, left they should receive any injuries from the external air. It is first to be examined, however, whether they have received any wound or not, and whether they preserve their natural warmth and colour; for where they are cold, livid, or dry, or wounded, they are not to be returned suddenly, but fomented with warm milk and water, or wrapped up for some time in the cawl of some animal newly killed, till they have in some degree recovered their native warmth and condition.

You will easily perceive, that there is some hurt in the intestines, though the wound does not immediately appear, if there is more than ordinary flaccidity in them; and when this is the case, the rest of the intestines must be pulled gently forward till you find the wound. If nothing of this sort is the case, but the intestines are in their natural state and condition, they must be returned in the following manner: the patient must be placed in a supine posture, and laid on that side that is opposite to the wound, and the intestine must be returned by the aperture of the wound with the two fore-fingers, taking

care never to take off one finger till the other is on the gut; the patient is to be advised all the while to hold his breath, and the lips of the wound must be then brought together.

If the intestines have been forced through a small wound, and are afterwards so distended with wind, that they cannot eafily be returned, it is neceſſary to pull the intestine gently forward, that more of it may come out, and the wind take up by that means leſs room in any one part; an aſſiſtant muſt then gently dilate the wound as far as may be, either with his hand, or with two hooks fixed in the internal membrane; while the ſurgeon returns the inteſtines; when this is done, the wound muſt be ſtroked firſt with the hand, and then with the proper dreſſings; and in this caſe the ſurgeon may avoid the uſe of this painful operation.

When it is found neceſſary to perform this operation, it muſt be done in the following manner: firſt pass a ſtrong double or quadruple thread, well waxed, through two crooked needles, and with theſe ſtitch up both ends of the wound, beginning at one end with the upper lip of the wound, paſſing the needle through the peritoneum, muſcles of the abdomen, and the common integuments, from within outwards, leaving only the breadth of a thumb between the ſtitches and the mouth of the wound, obſerving the ſame method in paſſing the other needle through the lower lip: while you are paſſing the needle with one hand, it will be proper to ſupport the lips of the wound with the other, to prevent the inteſtines from being wounded. In a wound of two fingers breadth, one ſtitch in the middle will be ſufficient; but in larger wounds, the ſtitches muſt be repeated in proportion to their ſize, leaving a thumb's breadth between each of the ſutures; the extremities of the thread are to be left hanging down on each ſide; and when the ſuture is finiſhed, while an aſſiſtant holds the lips of the wound together, theſe ends are to be tied in knots in the following manner: both ends of the threads are to be taken up, and to be tied firſt in a ſingle, then in a flip knot, paſſing a ſmall boiler between the two knots, to prevent the ſkin from being hurt. When there are more ſutures than one, you muſt begin at the upper part of the wound, tying them down in order, that before the laſt is tied, a ſoft tent, of the ſize of a finger, with a thread faſtened to the end of it may be introduced into the lower part of the wound. This tent will keep a paſſage open for the evacuation of grumous blood, or matter, which may be collected in the cavity of the abdomen. The wound, when all this is done, muſt be anointed with ſome vulnerary balſam, and covered with pledgets of lint, a ſticking plaiſter, and boliſter, ſecuring all with the ſcapulary bandage. Large wounds alſo extending to the peritoneum, but not penetrating it, require this operation to prevent bad ſymptoms, and dangerous hernie from a diſtenſion of the membrane; but in this caſe the needle muſt paſs only through the muſcles and common integuments. Heiſter's Surgery, book i. chap. 5.

GASTROTOMY, of γαστηρ, and τεμνω, *I cut*, the operation of cutting open the belly; otherwiſe called the Cæſarian *ſection*. See alſo LITHOTOMY.

GASULON, in the *Materia Medica*, a word uſed by Avicenna and Serapion, to expreſs ſometimes the plant *henbane*, and ſometimes *nitre*. Theſe are two very different things to be known under the ſame name; but the proper interpretation of the word being the *cleaning of cloaths*, it was uſed probably at ſome time to ſignify every thing of an abſterſive quality; but among the many things of this kind once called by it, the two above mentioned are all that we had recoided, which may be eaſily diſtinguiſhed by the context.

GATE, in *Architecture*, a large door, leading or giving entrance into a city, town, caſtle, palace, or other conſiderable building.

Thebes, in Egypt, was anciently known by the appellation, *with a hundred gates*. Fez, in Africa, has thirty-one *gates*. In ancient Rome there was a triumphal *gate*, *porta triumphalis*; in modern Rome theſe is the *Jubilee gate*, which is only opened in the year of a grand JUBILEE.

The *gates* of London were many of them converted into goals or priſons, as *Ludgate*, *Newgate*, &c. but they are now removed. The leſſer, or *by-gates*, are called *poterns*. Gates through which coaches, &c. are to paſs, ſhould not be leſs than ſeven feet broad, nor more than twelve; the height to be 1½ the breadth.

GATE, or GATT, in the *Manege*, called in French *traite*, is uſed for the going or pace of a horſe.

GATE, in a *military ſenſe*, is made of ſtrong planks, with iron bars, to oppoſe an enemy. They are generally made in the middle of the curtin, from whence they are ſeen, and defended by the two flanks of the baſtion. They ſhould be covered with a good ravelin, that they may not be ſeen or enfiladed by the enemy. Theſe gates belonging to a fortified place, are paſſages through the rampart, which may be ſhut or opened by means of doors and a PORTCULLIS. They are either private or public.

Private *gates* are thoſe paſſages by which the troops can go out of the town unſeen by the enemy, when they paſs to and from the relief of the duty in the works, or on any other occaſion which is to be concealed from the beſiegers.

Public *gates* are theſe paſſages through the middle of ſuch curtins, to which the great roads or public ways lead. The dimenſions of theſe are uſually about thirteen or fourteen feet high, and nine or ten feet wide, continued through the rampart, with proper receſſes for foot paſſengers to ſtand in out of the way of wheel-carriages. The front of the *gate*-way on the outſide is commonly ornamented with architecture either of the Tuſcan or Doric order; and over the vault, which covers the paſſage, cloſe to the town wall, is erected a building of about eighteen or twenty feet ſquare, in which the portcullis is ſuſpended; and on the inſide of the rampart there is generally another building, of about a hundred feet in front, and thirty deep, and high enough to contain one or two floors of rooms for one of the town officers; the ground floor ſerving for guard-rooms for the troops on duty at the *gate*. See HARROW, HERSE, ORGAN, and PORTCULLIS.

GATE, *poſtern*. See SALLY-*port*.

GATE *of the ſea*, or a *ſea-gate*, is uſed when two ſhips lie aboard one another in a wave or billow, and by that means ſometimes become *ſide-locks*.

GATES, *opening of*, in *Aſtrology*. See OPENING.

GATHER, in the *Sea-language*. A ſhip is ſaid to *gather* on another, when ſhe gets the wind of her.

GATTUGO, in *Ichthyology*, a name given by ſome to an American fiſh, a ſpecies of the tortus or wraſſe, of a yellow colour, and beautifully variegated with red, called by moſt authors by its Braſilian name, THE A *piranga*.

GAVAL, in the *Materia Medica*, a name given by ſome of the old writers to ASBESTUS, particularly to the Arabian kind, which was the pureſt, and was uſually in form of ſmall fears, and of a pale yellowiſh colour.

GAVEL, or GABEL, in *Law*, ſignifies tribute, toll, cuſtom, yearly rent, payment, or revenue, of which there were anciently ſeveral kinds: *gavel-corn*, *gavel-malt*, *gavel-ſeed*, *gavel-ſheaf*, &c.

GAVEL is ſometimes alſo uſed for what we more uſually call the GABLE.

GAVELET, GAVELETUM, in *Law*, a ſpecial and ancient kind of ceſſavit uſed in Kent, where the cuſtom of gavel-kind continues; whereby the tenant muſt forfeit his lands and tenements to the lord, if he withdraw from him his due rents and ſervices.

The proceſs of the *gavelet* is thus: the lord is firſt to ſeek by the ſteward of his court, from three weeks to three weeks, to find ſome diſtreſs upon the tenant, till the fourth court; and if, at that time, he find none, at this fourth court it is awarded, that he take the tenement in his hand, in name of a diſtreſs, and keep it a year and a day without manuring; within which time, if the tenant pays his arrears, and make reaſonable amends for the waſte-building, he ſhall have and enjoy his tenement as before: if he come not before the year and day be paſt, the lord is to go to the next county court, with witneſſes of what had paſſed at his own court, and pronounce there his proceſs to have farther witneſſes; and then, by the award of his own court, he ſhall enter and manure the tenement as his own; ſo that, if the tenant ſeiſre afterwards to have and hold it as before, he muſt agree with the lord, according to this old ſaying: "has "he not once any thing given, or any thing paid, then "let him pay five pound for his were, ere he become "bouſder again." Other copies have the latter part with ſome variations; "let him nine times pay, and nine "times repay."

GAVELET, in London, a writ uſed in the buſineſs of London, *breve de gavelecto in London. pro reditu inde quia tenementa fuerunt indistringibilia*. And the ſtatute of *gavelet*, 20 Edw. II. gives this writ to lords of land in the city of London, as well as in Kent. Here the parties, tenant and demandant, appear by *ſuit*, and to ſhew cauſe why the one ſhould not have his tenement again, on payment of his rent, or the other recover the lands, on default thereof.

GAVELKIND, a tenure or cuſtom, whereby the lands of the father are equally divided, at his death, among all his ſons; or the land of the brother among all the brethren, if he have no iſſue of his own.

Lambard compounds this term of the three Saxon words *tyſe*, *eal*, *tyn*, *omnibus cognitum proximum dato*. Verſtegan calls it *gavelkind*, quaſi *give all kind*, i. e. to each child

child his part; and Taylor, in his History of *Gavelkind*, derives it from the British *gavel*, i. e. a hold or tenure, and *cenedl*, or *cenedl*, *generatio*, or *familia*, and thus *gavel cenedl* might signify *tenura generationis*.

Testimonio perhibet patrocinii fecundia agrestis
Mistaria sterps omnis, ne fiert ullo patens.

This custom, which anciently obtained throughout England, is still in force to a great part of Kent, Ufferchefield in Herefordshire, and elsewhere, though with some distinctions: but, by the stat. 34 and 35 Hen. VIII. c. 26. all *gavelkind* lands in Wales are made descendible to the heir, according to the course of common law; whereby it appears, that this tenure was also in that principality; and was probably of British original.

In an ancient book of records in Christ-church, Canterbury, of the time of Henry VIII. our Saxon ancestors are said to have held all their lands either by writing, or without: the first were called *bocland*, whose owners were men, whom we now call *freeholders*: the second were called *folkland*, the owners whereof were of servile condition, and possessed *ad voluntatem domini*. Now the inheritance, or freehold, did run, in those days, descend to the eldest son, but to all alike; which, in Saxon, was called *bandesfyssum*, and, in Kent, to *first land*; whence came the custom *gavelkind*. And the reason why it was retained in Kent more than other places, was that the people of Kent, upon the Norman invasion, could not be reduced to surrender to the Conqueror, but on these conditions, that they should retain their ancient county-customs without any infringement or diminution; and especially that called *gavelkind*.

In the reign of Hen. VI. there were not above thirty or forty persons in the whole county in Kent, who held by any other tenure than this of *gavelkind*; which was afterwards altered upon the petition of several Kentish gentlemen, with regard to great part of the land of that county, to be descendible to the eldest son according to the course of common law: by 31 Hen. VIII. c. 3. Though the custom to devise *gavelkind* land still remains; and all lands in Kent shall be taken to be *gavelkind*, except those which are *disgavelled* by particular statutes. The distinguishing properties of this tenure are various; some of the principal are these: the lands, held under this denomination of *gavelkind*, which is an ancient socage tenure, descend equally, and are divided, share and share alike, among all the male children; and, in default of these, among the females. They are of age, or qualified to take the lands upon them, at fifteen; and may then give, vend, or alienate the same to any person, without the consent of any lord: and children here inherit their father's land, though convicted of felony, murder, &c. according to the maxim, "The father to the bough, the son to the plough." The tenants in *gavelkind* are to do fealty, and to be in the tuition of the next akin, who is not next heir after them, till fifteen years of age; to pay acknowledgement to the lord for the lands, &c.

GAVELMAN, a tenant who is liable to tribute.

Villani de Torring, qui vocantur gavelmanni. Somner, *Gavelkind*.

GAVELMED, the duty or work of mowing grass, or cutting of meadow land, required by the lord from his customary tenants. *Confectudo falcandi quæ vocatur* gavelmed. Somner.

GAVELRIP, bedrep, or duty of reaping, at the command of the lord—*de consuetudine metendi 40 acras & dimid. & gavelrip in autumno 40 sol. & sex denar.*

GAVELSESTER, *festucarius vectigalis*, a certain measure of rent ale. Among the articles to be charged on the stewards and bailiffs of the manors belonging to the church of Canterbury in Kent, according to which they were to be accountable, this of old was one: *de gavelsestar cujuslibet braciatoris braciatis infra libertatem maneriorum, &c. Unam lagenam & dimidiam circiter.* This duty elsewhere occurs under the name of *tassester*, in lieu whereof, the abbot of Abingdon was wont of custom to receive the penny mentioned by Selden, in his dissertation annexed to Fleta, c. 8. Nor does it differ from what is called *cadgeral* in the glossary at the end of the laws of Henry I.

GAVELWERK, was either *manu-opera*, by the hands and persons of the tenant, or *carr-opera*, by his carts or carriages.

GAUGE-*boat*, a line on the common gauging rod, whole description and use see under the article GAUGING.

GAUGE-*point* of a solid measure, is the diameter of a circle, whose area is equal to the solid content of the same measure.

Thus, the solidity of a wine gallon being 231 cubic inches; if you conceive a circle to contain so many inches, the diameter of it will be 17.15; and that will be the *gauge-point* of wine-measure.

And an ale gallon containing 282 cubic inches; by the same rule, the *gauge-point* for ale-measure will be found to be 19.151; and after the same manner may the *gauge-point* of any other measure be determined.

Hence we deduce, that when the diameter of a cylinder in inches is equal to the *gauge-point* in any measure given likewise in inches; every inch in length the said will contain an integer of the same measure. As a cylinder, whose diameter is 17.15 inches, every inch in height contains one cylic gallon in wine-measure; and in another, whose diameter is 19.15, every inch in length contains one ale gallon.

GAUGER, an officer appointed by the king to gauge, i. e. to examine or measure all casks, tuns, pipes, barrels, hogsheads of beer, wine, oil, &c. and to give them a mark of allowance (which is a circle burnt with an iron) before they be sold in any place within the extent of this office.

Of this officer, and his office, we have many statutes; thus, by 27 Edw. III. c. 8. all wines, &c. imported, are to be gauged by the king's *gaugers* or their deputies; by 31 Edw. III. c. 5. selling wine before gauged, incurs forfeiture, or the value: and by 23 H. VI. c. 16 the gauge-penny is to be paid *gaugers* on gauging wines. The 31 Eliz. ordains that beer, &c. imported shall be gauged by the master and wardens of the cooper's company: see 12 Car. II. c. 4. See EXCISE.

GAUGING, the art or act of measuring the capacities or contents of all kinds of vessels, and determining the quantity of fluids, or other matters, contained therein.

Gauging is the art of reducing the unknown capacity of vessels of divers forms, cubical, parallelepipedal, cylindrical, spheroidal, conical, &c. to some known cubic measure; and of computing, for instance, how many gallons, quarts, pints, or the like, of any liquor, e. g. ale, beer, wine, brandy, &c. are contained therein.

Gauging is a branch of *stereometry*.

The principal vessels that come under its operation are pipes, barrels, runlets, and other casks; also backs, coolers, vats, &c.

The solid content of cubical, parallelepipedal, and prismatical vessels, is eafily found in cubic inches, or the like, by multiplying the area of the base by the perpendicular altitude.

And for cylindrical vessels, the same is found by multiplying the area of the circular base by the perpendicular altitude, as before.

Casks of the usual form of hogsheads, kilderkins, &c. may be considered as segments of a spheroid cut off by two planes perpendicular to the axis; which brings them to Oughtred's theorem for measuring ale and wine casks; which is thus: add twice the area of the circle at the bung to the area of the circle of the head; multiply the sum by one-third of the length of the cask, the product is the content of the vessel in cubic inches. But, for accuracy, Dr. Wallis, Mr. Caswell, &c. think, that most of our casks had better be considered as frustums of parabolic spindles, which are less than the frustums of spheroids of the same base and height, and give the capacity of vessels nearer the truth than either Oughtred's method, which supposes them spheroids; or than that of multiplying the circles of the bung and head into half the length of the cask, which supposes them parabolic conoids; or than that of Clavius, &c. who takes them for two truncated cones; which is farthest off of all.

The common rule for all wine or ale casks is to take the diameters at the bung, and at the head, by which you may find the area of the circle there; then taking two thirds of the area of the circle at the bung, and one-third of the area of the circle at the head, and adding them together into one sum, this sum, multiplied by the internal length of the cask, gives the content in solid inches; which are converted into gallons, by dividing by 282 for ale, and by 231 for wine gallons.

The readiest method for common use is to reduce the cask to a cylinder of equal contents; and this is done by considering what is called the variety of the cask. Suppose a cylinder inscribed in a cask, and another circumscribed about it, there will be a cylindrical space included between the superficies of the two cylinders, whose diameter or thickness is equal to the difference between the bung and head diameters of the cask; the curvature of the staves of the cask takes in a certain proportion of the cylindrical space, which is greater or less, as the curvatures bend, or bulging of the staves is greater or less; and this determines what is called the variety; and it will be the first variety, if the cask bulges very much, second variety, if less, and so on; it is, therefore, evident, that the diameter of the inscribed circle may be increased so as to take in a portion of the intervenient cylindrical space equal to that taken in by the curvature of the staves of the cask; and then the cask and

increased

increased cylinder will be equal in content. The diameter of the inscribed cylinder is the head diameter of the cask; the thickness of the cylindrical space is equal to the difference between the bung and head diameters. The only difficulty, therefore, lies in determining what portion of this difference must be added to the head diameter of the cask, in order to obtain the diameter of the mean cylinder, or the cylinder of equal content. Now experience shews, that if $\frac{2}{3}$ of the difference between the head and bung diameters of any cask be added to the head diameter, the cylinder whose diameter is equal to this sum, and whole length is equal to that of the cask, will contain as much or more than that cask, though the staves have the greatest degree of curvature that is ever given to them. And as the difference between the bung and head diameters of casks is seldom very great, the contents of a cask whose staves are quite strait from bung to head, or of a cask made up of two equal frustums of two equal cones, will generally be nearly equal to the contents of a cylinder, whose diameter is equal to the sum of the head diameter of the cask, and a little more than half the difference between the bung and head diameters, and whose length is equal to the length of the cask. Therefore, all the varieties of which casks are capable lie between $\frac{1}{2}$ and $\frac{2}{3}$ of the difference between the bung and head diameters; and the gauger has only to take such a part of this difference (always between $\frac{1}{2}$ and $\frac{2}{3}$) as his judgment and experience inform him to be most suitable to the curvature of the cask; and this, added to the head diameter, gives the diameter of the mean cylinder.

It may not be amiss to note here, that the difference between the bung and head diameters may be very great, and yet the cask have no bulging at all, for the bulging is the head, or curvature of the shaft staves, between the bung and the head.

Mathematicians give us sublime theorems, for computing the contents of casks, upon the supposed resemblance between the curvature of the cask and that of an ellipsis, parabola, or hyperbola; but they may be as much mistaken in judging of the curvature, as an experienced gauger between $\frac{1}{2}$ and $\frac{2}{3}$: for after all, the contents of casks cannot be determined to a mathematical exactness; because the forms of casks do not exactly answer any mathematical figures. The business of gauging is at best but guess work; but it is such a way of guessing, as comes near enough the truth for the common purposes of life.

Here we may add such decimal multipliers, for the difference between bung and head diameters as have been found by experience to be the truest, and best suited to the several varieties or curvatures of casks.

First variety, or staves very much bulging,	,7 or ,695
Second variety, or staves not so much curved,	,665 or ,63
Third variety, or staves full less curved,	,6 or ,580
Fourth variety, or staves almost strait,	,555 or ,53

The following rule will serve for gauging casks by the pen: take the difference of the bung and head diameters of any cask, and multiply that difference by the number which stands against the name of the cask given in the table; add the product to the head diameter; and the sum will be the diameter of a cylinder, which, being of the same length with the given cask, will contain as much; square the diameter thus found, and multiply that square by the length, and divide the product by 359 for beer gallons, and 294 for wine.

The multipliers for a cask, which is taken for varieties.

The middle frustum	of a spheroid	,5	greatest bulge.
	of a parab. spindle	,4285	next less.
	two conoids	,356	next less to that.
	two cones	,254	next less to that.

Example. Let a cask be taken as the middle frustum of a spheroid, the bung diameter of which is 32 inches, the head 26, and length 50 inches; what is the content in beer and wine gallons? $32-26\times,5=4.2$. To which add 26, and we shall have 30.2 for the mean diameter; and $30.2^2=912,04$ which multiplied by the length 50 will give $45602,5$ and $\frac{45602}{359}=127$ beer gallons; and $\frac{45602}{294}=155,1$ wine gallons. The contents of other casks may be found in the same manner by using the proper multipliers. Post. Dict. Com. See Everard's Sliding Rule.

For the ready computation of the contents of vessels or of any solids in the measures in use in Great Britain, we shall here insert the following rules taken from a Treatise of Practical Geometry, published at Edinburgh in 1745. 8°. Vide pag. 137. seq.

1°. To find the content of a cylindric vessel in English wine gallons, the diameter of the base and length of the vessel being given in inches and decimals of inches: square the number of inches in the diameter of the vessel; multiply this square by the number of inches in the height, then multiply this product by the decimal fraction 0,0034, and you will have the contents of the vessel in gallons, and decimals of a gallon. For example, let the diameter be $=D=31,2$ inches, the height $=H=65,3$ inches, then will the content be $D\,D\,H\times,0034=31,2\times31,2\times65,3\times,0034=555,27342$ wine gallons.

2°. Supposing the English ale gallon to contain 282 cubical inches, the content of a cylindric vessel is computed in inch gallons, by multiplying the square of the diameter of the vessel by its height as before, and their product by the decimal fraction 0,003651, that is, the solid content in the gallons will be $D\,D\,H\times0,003651$.

3°. If the Scotch pint contains 103,4 cubical inches, the content of such a vessel in Scotch pints, will be $D\,D\,H\times0,0096$.

4°. Supposing the Winchester bushel to contain 2178 cubic inches, the contents of a cylindric vessel is computed in those bushels, by squaring the diameter of the vessel as before, and the product by the decimal fraction 0,000367. But the legal Winchester bushel containing only 2150,42 cubical inches, the content of a cylindric vessel is computed in such bushels, by multiplying the square of the diameter by the height, and their product by the decimal 0,000362. Or the content will be $D\,D\,H\times0,000362$. See Bushel.

5°. Supposing the Scotch wheat firlot to contain 21½ Scotch pints, or about 2193 cubical inches, the contents of a cylindric vessel in such dimensions will be $D\,D\,H\times0,00238$. And if the barr firlot contain 31 Scotch pints, the contents of such a vessel in barr firlots will be $D\,D\,H\times0,003245$. See Firlot.

6°. It is to be observed, that when the section of the vessel is not a circle, but an ellipsis, the product of the greatest diameter by the least is to be substituted in these rules, for the square of the diameter.

7°. To compute the contents of a vessel, which may be considered as the frustum of a cone in any of those measures. Let A represent the number of inches in the diameter of the greater base, B the number of inches in the diameter of the lesser base. Compute the square of A, the product of A by B, and the square of B. Take the third part of the sum of all these, and substitute it in the preceding rules for the square of the diameter, and proceed in all respects as before. Thus for example, the content in wine gallons will be $A\,A+A\,B+B\,B\times,0034$. Or thus: to the square of half the sum of A and B add one third of the square of half their difference; and substitute this sum in the preceding rules for the square of the diameter of the base of the vessel. For the square of $\frac{1}{2}A+\frac{1}{2}B$ added to $\frac{1}{3}$ of the square of $\frac{1}{2}A-\frac{1}{2}B$ gives $\frac{1}{4}AA+\frac{1}{2}AB+\frac{1}{4}BB+\frac{1}{12}AA-\frac{1}{12}AB+\frac{1}{12}BB=\frac{1}{3}AA+\frac{1}{3}AB+\frac{1}{3}BB$.

8°. When the vessel is a frustum of a parabolic conoid, measure the diameter of the section at the middle of the height of the frustum; and the content will be the same as of a cylinder of this diameter, of the same height with the vessel.

9°. When a vessel is a frustum of a sphere, if you measure the diameter of the section at the middle of the height of the frustum, that compute the content of a cylinder of this diameter, and of the same height with the vessel, and from this subtract $\frac{1}{3}$ of the content of a cylinder of the same height, on a base, the diameter of which is equal to that height; the remainder will give the content of the vessel. That is, if D represent the diameter of the middle section, and H the height of the frustum, you are to substitute $DD-\frac{1}{3}HH$ for the square of the diameter of the cylindric vessel in the first six rules.

10°. When the vessel is a frustum of a spheroid, if the bases are equal, the content is readily found by the rules given from Cuphitred. In other cases, let the axis of the solid be to the conjugate axis, as 1 to 1; let D be the diameter of the middle section of the frustum, H the height or length of the frustum, and substitute in the first six rules $DD-\frac{HH}{3^{aa}}$ for the square of the diameter of the vessel.

11°. When the vessel is a hyperbolic conoid, if the axis of the solid be to the conjugate axis as a to 1, if the diameter of the section at the middle of the frustum be D, the height or length, compute $DD+\frac{HH}{3^{aa}}$ and substitute this sum for the square of the diameter of the cylindric vessel in the first six rules.

12°. In general, it is useful to measure any round vessel distinguishing it into several frustums, and taking the diameter

diameter of the section at the middle of each frustum; thence to compute the content of each, as if it was a cylinder of the mean diameter; and to give their sum as the content of the vessel. From the total content computed in this manner they subtract successively the numbers which express the circular areas that correspond to those mean diameters, each as often as there are inches in the altitude of the frustum to which it belongs, beginning with the uppermost; and in this manner calculate a table for the vessel, by which it readily appears how much liquor is at any time contained in it, by taking either the dry, or the wet inches; having regard to the inclination, or drip of the vessel, if it has any.

This method of computing the content of a frustum from the diameter of the section at the middle of its height, is exact in that case only when it is a portion of a parabolic conoid; but in such vessels as are in common use the error is not considerable. When the vessel is a portion of a cone or hyperbolic conoid, the content by this method is found less than the truth; but when it is a portion of a sphere or spheroid, the content computed in this manner exceeds the truth. The difference or error is always the same in the different parts of the same, or of similar vessels, when the altitude of the frustum is given. And when the altitudes are different, the error is in the triplicate ratio of the altitude. If exactness be required, the error in measuring the frustum of a conical vessel, in this manner, is $\frac{1}{3}$ of the content of a cone, similar to the vessel, of an altitude equal to the height of the frustum. In a sphere it is $\frac{1}{5}$ of a cylinder, of a diameter and height equal to the frustum. In the spheroid and hyperbolic conoid, it is the same as in a cone, generated by the right-angled triangle contained by the two semiaxes of the figure revolving about that side which is the semiaxis of the frustum. These are demonstrated in a treatise of fluxions by Mr. Mac Laurin, where those theorems are extended to frustums that are bounded by planes oblique to the axis in all the solids, that are generated by any conic section revolving about either axis. Vide p. 23. and 715.

In the usual method of computing a table for a vessel, by subducting from the whole content the number that expresses the uppermost area, as often as there are inches in the uppermost frustum, and afterwards the numbers for the other areas successively, it is obvious that the contents assigned by the table, when a few of the uppermost inches are dry, are stated a little too high, if the vessel stands on its lesser base, but too low when it stands on its greater base; because, when one inch is dry, for example, it is not the area at the middle of the uppermost frustum, but rather the area at the middle of the uppermost inch, that ought to be subducted from the total content, in order to find the content in this case.

But *gauging*, as now practised, is chiefly done by means of instruments called *gauging-rods*, or *rules*, which do the business at once, and answer the question without so much calculation; which is no inconsiderable addition, both to the ease and dispatch of the work. This instrumental way of *gauging*, therefore, we shall here chiefly insist upon.

Construction of a GAUGING-*rod, whereby the content of any cylindrical, or common vessel, is easily had.* Take the diameter AB of a cylindrical vessel, ABDE, *Tab. Surveying fig.* 11. that holds one of the measures wherein the fluid is estimated, e. gr. gallons, and join it at right angles to the indefinite line A 7. From A to 1, set off a right line equal to AB; then will B 1 be the diameter of a vessel, that holds two measures, or gallons, of the same height as the former.

Again, let A 2=B 1; then will B 2 be the diameter of a vessel that holds three measures, but of the same height as that which only holds one. And, after the same manner, find the diameter of other large vessels, B 3, B 4, B 5, B 6, B 7, &c.

Lastly, let off the several divisions thus found, A 1, A 2, A 3, &c. upon the side of a rod or rule: and, on the other, the height or depth of a cylinder, that holds one measure or gallon, repeated as oft as it will go. Thus is the *gauging-rod* complete.

For cylinders, that have the same altitude, are to each other as the squares of their diameters; consequently the square of the diameter of the vessel that holds 2, 3, or 4 gallons, must be double, triple, or quadruple of that, which only holds one. And since in the first, AB=A 1, the square of B 1 is double, that of B 2 triple, that of B 3 is quadruple, &c. it is evident, that the right lines A 2, A 3, A 4, &c. are the diameters of the vessels required.

These divisions, therefore, being applied to the side of a cylindrical vessel, it will immediately appear how many measures, e. gr. gallons, a cylindrical vessel of that base, and of the height of that which holds one gallon, will contain.

Wherefore, finding by the divisions on the other side of the rod, how often the height of one gallon is contained in the height of the given vessel; and multiplying the diameter before found by this number, the product will be the number of gallons the vessel contains.

Thus, e. gr. if the diameter of the cylindrical vessel be 8, and its height 12, its contents will be 96 gallons.

Note, 1°. The less you take the height of the cylinder containing one gallon, the greater will the diameter of the base be: whence both that, and the diameters of the cylinders containing several gallons, will be the more easily divisible into lesser parts. Bayer directs such height to be only one digit, or tenth of an inch.

2°. The diameters of vessels holding one or more decimal parts of a gallon will be had, by dividing one or more decimal parts of the vessel holding a whole gallon, by its height; which gives us the area of the circular base; from whence the diameter is easily found by the rules delivered under DIAMETER, CIRCLE, &c. And after the same manner, the diameters are found for the divisions of vessels, that hold two or more gallons.

GAUGING-*rod, use of the.* To find the content of a cask; that is, to determine the number of measures, e. gr. gallons, it will hold: apply the *gauging-rod* to the vessel, as directed in the preceding article, and find both the length of the cask, AC, *fig.* 12. and both diameters, GH, and AB. Now, as we find, by experiment, how far soever it may be from geometrical exactness, that a common cask of this form may safely enough be reputed as a cylinder, whose base is a medium between the head and the belly; find such medium, which call the *equated diameter*.

Then multiplying the number thus found by the length of the cask AC, the product will be the number of measures the vessel contains.

Suppose, e. g. AB=8. and GH=12, and AC=15, the equated diameter will be 10, which multiplied by 15, gives the capacity of a cask, 150 measures.

If it happen, that the diameters of the two ends be not equal, measure them both, and take half their sum for the diameter to work by.

There is another method whereby the content of a vessel is had, without any calculation at all, which obtains in divers parts of Germany and the Low-Countries: but as this supposes all vessels to be similar to each other, and their length double of the equated diameter, that is, of half the sum of the diameters AB, and GH, it is not safe to use it in all places. Keplery, however, prefers it to much before all others, as including all the precautions possible, that he recommends it to the public, to enact it by law, that all casks be made in this proportion.

The methods of *gauging*, which chiefly obtain among us, are, by the four-foot *gauging-rod*, and Everard's *sliding-rule*.

GAUGING-*rod, description and use of the four-foot.* The four-foot *gauging-rod*, represented in *Tab. II. Surveying, fig.* 20. is usually made of box, and consists of four rules each a foot long, and about three-eighths of an inch square, joined together by three brass joints; by which means the rod is rendered four feet long, when the four rules are quite opened, and but one foot when they are all folded together.

On the first face of this rod, marked 4, are placed two diagonal lines; one for beer, and the other for wine: by means of which the content of any common vessel in beer or wine gallons may be readily found, by putting the rod in at the bung-hole of the vessel, till it meets the intersection of the head of the vessel with the staves opposite to the bung-hole. For distinction of this line, there is written thereon, *beer* and *wine gallons*.

On the second face, 5, are a line of inches, and the gauge-line; which is a line expressing the areas of circles, whose diameters are the correspondent inches in ale gallons. At the beginning is written, *ale area*.

On the third face, 6, are three scales of lines; the first, at the end of which is written *hogshead*, is for finding how many gallons there are in a hogshead, when it is not full, lying with its axis parallel to the horizon. The second line, at the end of which is written *B. L.* signifying a *butt lying*, is for the same use as that for the hogshead. The third line is to find how much liquor is wanting to fill up a butt when it is standing: at the end of it is written *B. S.* signifying a *butt standing*. In the half of the fourth face of the *gauging-rod*, 7, there are three scales of lines, to find the wants in a firkin, kilderkin, and barrel, lying with their areas parallel to the horizon. They are distinguished by letters *F. S. B.* signifying a *firkin*, *kilderkin*, and *barrel*.

GAUGING-*rod, use of the diagonal lines on the.* To find the content of a vessel in beer or wine gallons, put the brazed end of the *gauging-rod* into the bung-hole of the cask, with the diagonal lines upwards, and thrust this brazed

end to the meeting of the head and staves; then with chalk, make a mark at the middle of the bung-hole of the vessel, and also on the diagonal lines of the rod, right against, over one another, when the braked end is thrust home to the head and staves: then turn the *gauging-rod* to the other end of the vessel, and thrust the braked end home to the end, as before.

Lastly, see if the mark made on the *gauging-rod* come even with the mark made on the bung-hole, when the rod was thrust to the other end; which if it be, the mark made on the diagonal lines, will, on the same lines, shew the whole content of the cask in beer or wine gallons.

If the mark made on the bung-hole be not right against that made on the rod, when you put it the other way, then, right against the mark made on the bung-hole, make another on the diagonal lines; and the division on the diagonal line, between the two chalks, will shew the vessel's whole content in beer or wine gallons.

Thus, e. gr. if the diagonal line of a vessel be 28 inches four tenths, its content in beer gallons will be near 51, and in wine gallons 62.

If a vessel be open, as a half-barrel, tun, or copper, and the measure from the middle on one side, to the head and staves be 38 inches, the diagonal line gives 122 beer gallons; half of which, viz. 61, is the content of the open half tub.

If you have a large vessel, as a tun or copper, and the diagonal line, taken by a long rule, proves 70 inches; the content of that vessel may be found thus:

Every inch, at the beginning-end of the diagonal-line, will ten inches. Thus ten inches becomes 100 inches: and every tenth of a gallon will 200 gallons; and every whole gallon will 1000 gallons.

Exam. at 44,8 inches, on the diagonal beer-line, is 200 gallons; so that 4 inches 48 parts, now called 44 inches 8 tenths, is just two-tenths of a gallon, now called 200 gallons: so also, if the diagonal line be 70 inches and 7 tenths, a close cask, of such diagonal, will hold a 1000 beer gallons; but an open cask but half so much, viz. 500 beer gallons.

GAUGE-*rule, use of the.* To find the content of any cylindrical vessel in ale gallons; seek the diameter of the vessel in inches, and, just against it, on the *gauge-line*, is the quantity of ale gallons contained in one inch deep: this, multiplied by the length of the cylinder, will give its content in ale gallons.

For example, suppose the length of the vessel 32,06, and the diameter of its base 25 inches; to find what is the content in ale gallons?

Right against 25 inches, on the *gauge-line*, is one gallon, and 745 of a gallon; which multiplied by 32,06, the length, gives 35,9447 gallons for the content of the vessel.

The lung diameter of a hogshead being 25 inches, the head diameter 22 inches, and the length 32,06 inches; to find the quantity of ale gallons contained in it?

Seek 25, the bung diameter, on the line of inches; and right against it, on the *gauge-line*, you will find 1,745: take one third of it, which is ,580, and set it down twice: seek 22 inches in the head diameter, and against it you will find, on the *gauge-line*, 1,336; one-third of which added to twice ,580, gives 1,0096: which multiplied by the length 32,06, the product will be 51,803776, the content in ale gallons.

Note, this operation supposes, that the aforesaid hogshead is in the figure of the middle frustum of a spheroid.

The use of the lines on the two other faces of the rod, is very easy; you need only put it downright into the bung-hole (if the vessel you desire to know the quantity of ale gallons contained therein be lying) to the opposite staves; and then where the surface of the liquor cuts any one of the lines appropriated to that vessel, will be the number of gallons contained in that vessel.

The description and use of Everard's sliding-rule for *gauging*, see under STRINGER.

GAVIAON, in *Ornithology*, the name by which the Portuguese called the CARACARA, a species of Brasilian hawk, of the bignets of our kite.

GAVILAN, in *Natural History*, a name given by the Spaniards to a species of hawk, common in the Philippine Islands; it is somewhat larger than our sparrow-hawk, and is of a yellowish colour on the back and wings, and whitish under the belly; it is the most common of all the birds of prey in that part of the world, and is very voracious, and mischievous.

GAVIOTA, in *Ornithology*, the name given by the Portuguese to a water-fowl of the gull kind, common in Brasil, and called by the natives *guara guara*. It is of the size of a common hen; its beak is long, strait, and yellow; its head is black on the top, as is also the further half of the wings and tail: the throat, breast, and belly are white: it lays in the sand, and its eggs are of the size of those of the hen, and are accounted very good, but the flesh is not valued.

GAULISH *language*. See ROMAN, and FRENCH.

GAULONITÆ, among the *Jews*, the name of a faction rather than a religious sect, the same with the GALILEANS.

GAULTHERIA, in *Botany*, a genus of the *decandria monogynia* class: the exterior calyx is double-leaved, the interior is divided into five segments; the corolla is ovated; the nectarium has ten sharp points; and the fruit is a five-celled capsule. There is one species.

GAULUS, in *Antiquity*, a ship of a roundish form, mostly used by the people of Phœnicia.

GAULUS also signified a kind of cup.

GAUNT, an old word for lean, or lank. Thus, we say, a *gaunt* bellied, or light-bellied horse, when his belly shrinks up towards his flanks.

GAUNTLET. See GANTLET.

GAVOTTA, or GAVOTTE, derived from the *Gavots*, a people inhabiting a mountainous district in France, called Gap, in *Italian Alpi*, is a kind of dance, the air whereof has two strains, brisk and lively, and in common time; each of its strains are played twice over, the first has usually four or eight bars, and the second contains eight, twelve, or more. The time begins with a minim, or two crotchets, or notes of equal value, and the hand rising; and ends with the fall of the hand upon the dominant, or mediant of the mode, never upon the final, unless it be a rondeau. And the last begins with the rise of the hand, and ends with the fall upon the final of the mode.

The *Gavots* of Corelli, Albinani, Vivaldi and others of the Italians, correspond with these rules as far as they relate to the measure, the number of bars in each strain, and the cadences; but in respect to the initial notes of the air they deviate from it; for they sometimes begin with a whole bar, and sometimes with an odd quaver.

GAVOTTA, *tempo di*, in the *Italian Musick*, is when only the time or movement of a *gavotte* is imitated, without any regard had to the measure or number of bars, or strains. We often find parts of lessons, which have this phrase to regulate their motions.

GAURA, in *Botany*, a genus of the *octandria monogynia* class: the calyx is tubulous and divided into four segments; the corolla consists of four petals; and the fruit is a quadrangular nut, containing a single seed. There is one species.

GAURES, or rather GAUBES, or GABRES. See GABRES.

GAWSE, or GAWZE, in *Commerce*, a very thin, slight, transparent kind of stuff, woven sometimes of silk, and sometimes only of thread.

To warp the silk for making of *gawze*, they use a peculiar kind of mill, upon which the silk is wound: this mill is a wooden machine, about six feet high, having an axis perpendicularly placed in the middle thereof, with six large wings, on which the silk is wound from off the bobbins, by the axis turning round.

When all the silk is on the mill, they use another instrument to wind it off again on two beams: this done, the silk is passed through as many little beads as there are threads of silk; and thus rolled on another beam, to supply the loom.

The *gawze*-loom is much like that of the common weavers, though it has several appendages peculiar thereto. See LOOM.

There are figured *gawzes*, some with flowers of gold and silver, on a silk ground: these last are chiefly brought from China.

GAYAC. See GUAIACUM.

GAYTIPUA, in *Zoology*, the name of an American species of serpent, found as it is said only in the kingdom of Rezini. It grows to a vast size, and thinks so intolerably, that no creature can bear to be near it.

GAZA *gigantea*, in *Ornithology*, the name of a small species of *heron*, of a fine white colour, called by other authors *ardea alba minor*, or the *small white heron*. It is so small as not to weigh a pound. Its whole body is of a pure and perfect snow-white, and it has a short creft on the hinder part of its head, and a naked space without it, of a greenish about it's eyes. Its feet also are green, but sometimes covered with blackish scales. The feathers of the creft are very soft and white, and are much valued. It is eaten in Venice and Italy, and is sometimes cheap enough in the markets there. The creft feathers however are usually pulled off before it is offered to sale. Johnston.

GAZE-*hound*. See HOUND.

GAZELLA, GAZELLE, or ANTELOPE, is a species of the *capra*, or GOAT, in the Linnæan system; others have made it a distinct genus, with annulated, or twilled horns, eight broad cutting teeth in the lower jaw, and body

body and limbs of a light and elegant form. Thus, they make it an intermediate genus between the GOAT and DEER, agreeing with the first in the texture of their horns, which have a core in them, and they never cast them, and with the last in the elegance of their form and great swiftness. The agility and speed of this animal are surprising, so that the cheetah is a favourite diversion in the eastern nations. Some species of the antelope form herds of two or three thousand, while others keep in small troops of five or six. There are several species and varieties of this animal, which, excepting two or three, inhabit the hottest part of the globe. Their proper climates seem to be those of Asia and Africa, where they are very numerous. See ANTELOPE, and *Tab.* II. *Quadrupeds*, N° 14. which represents the white-footed *gazella*, or antelope of India, with short horns bending a little forward; large ears, marked with two black stripes; a small black mane on the neck and half-way down the back; a tuft of long black hairs on the fore-part of the neck; above that a large spot of white; another between the fore-legs on the chest; one white spot on each fore-foot; two on each hind foot; long tail tufted with black hairs; the height, to the top of the shoulders, about four feet, and the colour a dark grey. The female is of a pale brown colour, without horns, and having on each foot three transverse bands of black, and two of white. Pennant's Syn. of Quadr. p. 29.

GAZETTE, a news-paper, or printed account of the transactions of divers countries, in a loose sheet or half-sheet.

The word is formed from *gazetta*, a kind of coin, formerly current at Venice, which was the ordinary price of the first news-paper printed there: though others derive it, by corruption, from the Hebrew *izgad*, which signifies, *nuntius*, a messenger; but this etymology is too much forced.

Gazettes, which most people look on as trifles, are by some held the most difficult kind of compositions that have appeared. They require a very extensive acquaintance with the languages, and all the terms thereof, and a great facility and command of writing, and of relating with perspicuity, and in few words.

To write a *gazette*, a man should be able to speak of war both by land and sea; be thoroughly acquainted with every thing relating to geography, the history of the time, and that of the noble families; with the several interests of princes, the secrets of courts, and the manners and customs of all nations.

Vignuel de Marville recommends a set of *gazettes*, well written, as the truest books for the instruction of young persons coming into the world.

The first *gazette* published in these parts, is said to have been that of Paris, begun in the year 1631, by Theophrastus Renaudot, a physician of Montpelier, in his office of intelligencer.

GAZETTE, *extraordinary*. See EXTRAORDINARY.

GAZONS, in *Fortification*, turfs, or pieces of fresh earth covered with grass, cut in form of a wedge, about a foot long, and half a foot thick, to line or face the outsides of works made of earth, in order to keep up the fame, and prevent their mouldering.

GAZOPHYLACIUM, in the *Jewish Antiquities*, according to the Greek etymology of γαζα. *treasure*, and φυλασσω, *I keep*, fignifies the treasury-chamber. There were several places in the temple of Jerusalem, where the rich presents consecrated to God by kings, princes, or private persons were kept. But the fignification of this word *gazophylacium*, has been farther enlarged, so as to comprehend the rooms where the provisions of the temple were laid up, both for sacrifices, and for the support and sustenance of the priests, and in general this word is used for all the apartments of the temple. In the *Gospel*, by *gazophylacium* is meant the chest into which people cast their offerings at the entrance of the temple. It has been also used by naturalists for a collection of figures of curious subjects. Mark xii. 41, 43 Luke xxi. 1. Calm. Dict. Bibl.

GAZOPHYLAX, Γαζοφυλαξ, in *Antiquity*, an officer who had the care and management of the treasure belonging to the kings of Persia.

GAZZA, in *Ornithology*, the name of a species of *heron* common in Italy, and called by many authors *ardea alba minor*, the *greater white heron*. Its whole body is of a fnow white, its beak yellow, and the membranes about its eyes green; though called large in comparison of the leſſer white one, it is fmaller than the common grey heron. Its tail alſo is much longer, and it has no creſt. It is ſometimes ſeen in England, and has been miſtaken for a common heron become accidently white, as ſparrows and other birds ſometimes are.

GAZZETTA, in *Ornithology*, a name given by Gesner and others to a ſpecies of ſmall white heron, ſold in the markets of Italy, and ſeeming to be the *ardea alba minor* of authors, or GARZETTA of the Venetians.

GAZETTO, in *Ichthyology*, the name of a fiſh of the TURDUS, or wraſſe kind, caught in the Mediterranean, and ſold in the markets of Italy. It is of a fine green colour, and is conſiderably thick, though broad; its fins are ſpotted, and it has a large purple tubercle near the anus. It has only one back fin which has twenty-four ribs or nerves, the firſt fifteen of which are rigid and prickly, the laſt ſoft and ſtriate.

GEANNIDES, in *Natural Hiſtory*, a name given by ſome authors to the ſtone called by others encymonites. It ſeems to have been the ſame with our ſparry incruſtations on the tops of caverns, &c. but the word has been generally underſtood to mean the eagle ſtone. It was ſuppoſed to poſſeſs great virtues in helping delivery, and was given to women in their labours.

GEAR, or *about your* GEAR, at *ſea*, a command to work on all hands.

GEASTER, of γη, *earth*, and αστηρ, *ſtar*, in *Botany*, the name of a genus of fungites: or according to Linnæus, of ſome ſpecies of the genus of the LYCOPERDON. Theſe fungites have a radiated bottom like a ſtar, and in the centre of this there grows a round ball which opens at the top when ripe, and is found to be full of impalpable ſeeds in form of powder. See a deſcription and drawing of this plant by Dr. Watſon, in Phil. Tranſ. vol. xlviii. p. 334.

GECCO, in *Natural Hiſtory*, a name given by the Indians to their terrible poiſon, which kills in ever ſo ſmall a quantity when mixed with the blood. They ſay that this *gecco*, is a venomous ſtuff or humour, vomited out of the mouths of their moſt poiſonous ſerpents, which they procure in this fatal ſtrength, by hunting up the creatures by the tails, and whipping them to enrage them: they collect this in proper veſſels as it falls, and when they would uſe it, they either poiſon a weapon with it, or wounding any part of the fleſh, introduce the ſmalleſt quantity imaginable of it, and this is ſaid to be immediate death.

GECHYTON, of γη, *earth*, and χυω, *I pour*, a name given by ſome authors to the external covering of the earth, commonly called garden mould, which is ſoft and not ſtony.

GECOLITHUS, a corrupt way of ſpelling the word *lapis lithus*, the name of the lapis Judaicus among the Romans. The writers of the middle ages often write it *gecolithus*.

GED, in *Ornithology*, an Engliſh name for the ſmall ſpecies of ſnipe, uſually called the JUNDOCK, and by authors GALLINAGO *minima*.

GEERS, a general term for trappings, harneſs, and all other things, that belong to draught-horſes or oxen.

GEESE, in a *Ship*. See GOOSE.

GEGENES, Γεγενες, in *Antiquity*. The ancients generally called themſelves Γεγενες, *ſons of the earth*, as Heſychius informs us. Alluding to the ſame original, the Athenians ſometimes ſtyled themſelves Τεττιγες, *graſshoppers*; and ſome of them wore graſshoppers of gold, faſtened to their hair as badges of honour, to diſtinguiſh them from others of leſs antiquity, and leſs noble extraction, becauſe thoſe inſects were believed to be generated out of the ground. Poſt. Archæol. Græc. lib. i. cap. 6.

GEHENNA, Γεεννα, a ſcripture term, which has given ſome pain to the critics. It occurs in St. Matthew v. 22. 29. 30. x. 28. xviii. 9. xxiii. 15. 33. Mark ix. 43. 45. 47. Luke xii. 5. James iii. 6.

The authors of the Louvain and Geneva verſions retain the word *gehenne*, as it ſtands in the Greek; the like does M. Simon: the Engliſh tranſlators render it *by hell* and *hell-fire*; and the like do the tranſlators of Mons, and ſather Behours.

The word is formed from the Hebrew *gehinnom*, i. e. valley of Hinnom. In that valley, which was near Jeruſalem, there was a place named *Tophet*, where ſome Jews ſacrificed their children to Moloch, by making them paſs through the fire. King Joſias, to render this place for ever abominable, made a cloaca or common-ſewer there, where all the filth and carcaſes in the city were caſt.

The Jews obſerve farther, that there was a continual fire kept up there, to burn and conſume thoſe carcaſes; for which reaſon, as they had no proper term in their language to ſignify *hell*, they made uſe of that of *gehenna*, or *gehinnom*, to denote a fire unextinguiſhable.

GEHON. See GIHON.

GELÆOPACHIA, in *Natural Hiſtory*, the name of a claſs of mineral fluids, which are inflammable, and of ſomewhat thick texture, and opake. The word is derived from the Greek γη, the *earth*, and παχυς, *thick*. The bodies of this claſs are the Barbadoes tar, oil of earth, and the

the common pillaſphaltum of the ſhops, which ſee under their ſeveral heads.

GEL'EOPSILA, in *Natural Hiſtory*, the name of a claſs of foſſils. The word is derived from the Greek γη, *earth*, εσαμος, *ſoft*, and οψις, *thin*, and expreſſes a thin oily ſubſtance naturally found in the earth. Theſe are thin and pellucid inflammable liquid ſubſtances, commonly known by the name of liquid bitumens, but by that denomination confounded with the thicker and coarſer kinds. The only bodies of this claſs are thoſe commonly diſtinguiſhed by the names of NAPHTHA, and PETROLEUM.

GELALEAN *calendar*. See CALENDAR.

GELASANI *dentes*, a term uſed by ſome authors to expreſs the four middle fore teeth, both of the upper and under jaw. They have their name from the Greek, γελαω, *laughter*, becauſe they are ſhewn when people laugh.

GELATINA. See JELLY.

GELATINOUS, among the *Phyſicians*, is applied to any thing approaching the glutinous conſiſtence of a JELLY.

GELATO, properly ſignifies freezing, but is alſo uſed for that rigidity of the body and limbs, which comes on in the catalepſis, and other diſorders of that kind.

GELDUM, a name given by the Hungarian miners to a ſort of marcaſite or mundic, which contains a conſiderable quantity of ſilver.

GELD, or GILD, in our *Ancient Cuſtoms*, a mulct, or compenſation for a crime or delinquency. See GILD.

Hence *wergild* was anciently uſed for the value or price of a man ſlain; and *orfegild*, of a beaſt, &c.

Sit hoc ſcitte de Gelde, & Danegelde, Horngelde, & Fortgelde, & de Blodwita, & Fiumita, & Leirwita, & Hengwita, & Freemenſcelde, & Wardpeni, & Averpeni, & Hundredpeni, & Tollingpeni. Charta Ric. II. Priorat. de Hatland, in Devon.

GELD *feet*, GELD *horn*, and GELD *wood*, ſee the ſubſtantives.

GELDABLE. See GILDABLE.

GELDER-*roſe*, in *Botany*. For the characters, ſee WAYFARING-*tree*.

The common marſh elder, which grows naturally in marſhy grounds, and on the ſides of rivers in many parts of England, is not often kept in gardens: it is called by ſome the *gelder-roſe*, with flat flowers, to diſtinguiſh it from the other, whoſe flowers are globular. The marſh elder is the original ſpecies, and the *gelder-roſe* is a variety which accidentally ariſe from it. The former has a border of male flowers, which are large, and the middle of the umbel is compoſed of hermaphrodite flowers, which are ſucceeded by oval, red berries: the latter has all male flowers, of the ſame ſize and ſhape with thoſe of the border of the firſt, ſo that they ſwell out into a round figure, which has occaſioned ſome country people giving it the name of ſnow-ball tree. This ſort is cultivated in gardens for the beauty of the flowers, which make a fine appearance during their continuance.

It will riſe to the height of eighteen or twenty feet, if permitted to ſtand. The ſtem becomes large, woody, and hard; the branches come out oppoſite, and are apt to grow irregular; they have a grey bark. The leaves are placed oppoſite; they are divided into three or four lobes, ſomewhat like thoſe of the maple; the flowers come out at the ends of the branches; thoſe of the firſt in large umbels, and thoſe of the ſecond in a corymbus; they are very white, and appear the beginning of June. Thoſe of the firſt have ovel berries ſucceeding the hermaphrodite flowers, which turn of a ſcarlet colour when ripe, but the other having only male flowers are barren.

The common *gelder-roſe* ſends out plenty of ſuckers from the roots, by which it is frequently propagated; but as the plants ſo raiſed are very apt to put out ſuckers, they are not ſo good as thoſe which come from layers or cuttings; both ſorts love a moiſt ſoil. They are very hardy, and will thrive in the coldeſt ſituations, but not within the ſpray of the ſea. The common *gelder-roſe* is ſeldom ſuffered to ſtand very long in gardens; but one has been ſeen whoſe ſtem was more than two feet and a half round.

GELDING, the operation of caſtrating, and particularly horſes.

To *geld* a horſe, regard is to be had to their age, the ſeaſon of the year, and, as the farriers ſay, to the ſtate of the moon. For the firſt, if it be a colt, the operation may be formed at nine, or at fifteen days old, if the teſticles be come down; becauſe the ſooner he is *geld*, the better it will be for his growth, ſhape, and courage; though a horſe may be *gelded* at any age, if care be taken in the cure. As for the ſecond, the beſt time is about April or May, or elſe about the latter end of September; and for the third, the wane of the moon is preferred as the fitteſt time.

The manner of *gelding* is thus: the beaſt being caſt on ſome ſoft place, the operator takes the teſticles into his fore and great finger; ſlits the cod, and preſſes out the ſtones; then taking a pair of nippers made very ſmooth, either of ſteel, box, or brazil, he claſps the ſtrings of the ſtones between them, very near to where the ſtones are ſet on, and preſſes them ſo hard, that there may be no flux of the blood, and then ſears away the ſtone with a thin cauterizing iron, made red-hot

This done, he takes a hard plaiſter, made of wax, roſin, and waſhed turpentine, melted together, and melts it on the head of the ſtrings with the hot iron, and afterwards ſears the ſtrings, and melts more of the ſalve, till there is a good thickneſs of the ſalve laid on the ſtrings.

This being done to the ſtone, the nippers are looſened, and the like is done to the other; and the two ſtones of the cod are then filled with white ſalt, and the outſide of the cod anointed with hog's greaſe; and thus they let him lie, and keep him in a warm ſtable, without tying him up.

If he ſwells much in his cod or ſheath, they chafe him up and down, and make him trot an hour in a day, and he ſoon recovers. See CASTRATION and EUNUCH.

GELDING, in the *Manege*, is alſo uſed for a horſe, whoſe teſticles are cut out.

GELDUM, a name given by ſome to the philoſopher's ſtone.

GELFUM, or GELBUM, an Hungarian name for a kind of mundic, which contains ſilver.

GELLOSIA, in *Natural Hiſtory*, a name by which ſome of the writers of the middle ages call the CHALAZIAE.

GELOSCOPY, GELOSCOPIA, of γελως, *laughter*, and σκοπεω, *I conſider*, a kind of divination, drawn from laughter; or a knowledge of any perſon's character and qualities, acquired from the conſideration of his laughter.

GEM, or GEMM, GEMMA, a common name for all precious ſtones or jewels; conſiſting of the ſilicous, or what is improperly called vitrifiable earth, much valued for their luſtre, tranſparency, colour, hardneſs, weight, and rarity. Theſe are diamonds, rubies, ſapphires, topazes, emeralds, chryſolites, amethyſts, garnets, hyacinths or jacinths, beryls or aqua marinæ; the order in which they are enumerated ſhews their relative degree of hardneſs.

Dr. Hill diſtributes *gems* into two claſſes; viz. the pellucid *gems*, which are bright, elegant, and beautiful FOSSILS, always found in ſmall maſſes, extremely hard, of great luſtre, compoſed of a very fine and pure ſubſtance, giving fire with ſteel, not fermenting with acid menſtrua, and calcinable in the fire with great difficulty; of which there are two genera, the CHRYSTALLINA, and the ADAMANTACEA; and the ſemi-pellucid *gems*, which are defined to be ſtones, compoſed of a but ſlightly debaſed cryſtalline matter, of great beauty and brightneſs, of a moderate degree of tranſparence, and uſually found in ſmall maſſes. The bodies of this claſs are divided into two general orders, and under theſe into eight diſtinct genera. Of the firſt order are thoſe of but few variegations, and frequently of one plain ſimple colour, though ſometimes veined. Of the ſecond are thoſe remarkable for their veins, zones, and variegations. The genera of the firſt order, are the cornelians, chalcedonies, hydrophanæ, and prammion. Thoſe of the ſecond, are the agates, onyxes, ſardonyxes, and cameæ. See each of theſe under its proper head.

Others diſtinguiſh precious ſtones into three kinds:

1. Such as are entirely tranſparent; which again may be divided into ſuch as are either colourleſs, as the *diamond*; or coloured, as the *emerald*, *ruby*, &c. Which diviſion of coloured *gems* may be ſubdivided into thoſe of one colour, as the *ruby*; and thoſe with ſeveral, as the *opal*.

2. Brilliant, or ſhining, but leſs tranſparent, as the *Bohemian granate*.

3. Semi-tranſparent, as the *onyx*.

Biſhop Wilkins divides *precious* ſtones into *more* and *leſs tranſparent*.

The *leſs tranſparent* he diſtinguiſhes by their colours; into red, as the ſardian and cornelian; pale fleſhy colour, like that of a man's nail, as the onyx; bluiſh, as the turquois; and thoſe of various colours, as opal and cat's eye.

The *more tranſparent* he diſtinguiſhes into ſuch as are colourleſs, as the diamond and white ſapphire; and coloured, which are either red, as the ruby, carbuncle, and granate; yellow, as the chryſolite and topaz; green, as the emerald, ſmaragd, and beryl; bluiſh, as the ſapphire; and purple or violaceous, as the amethyſt.

Dr. Woodward divides precious ſtones ſomewhat more preciſely, into *opake*, *ſemi-opake*, and *tranſparent*.

The *opake* are either of one colour, as the turquois; or of various colours, as the lapis lazuli, and jaſper.

Semi-opake either have their colours *permanent*, as the agat, chalcedony,

chalcedony, onyx, sardonyx, cornelian, and beryl; or their colours vary according to the position of the light, as in the ocular cat, and opal.

Transparent flones are either *pale colours*; as the topaz and hyacinth, yellow; as partaking thereof; granate, ruby, and amethyst, red; sapphire, water sapphire, and aquamarine, blue; and emerald, or chrysolite, green, or partaking thereof; or *without colour*, as the chrystal, picodo-diamond, white sapphire, and diamond.

The natural history, characteristic properties, &c. of each ſtone, ſee under DIAMOND, CORNELIAN, RUBY, TURQUOIS, ONYX, EMERALD, CHRYSOLITE, &c. For the medicinal virtues of *precious ſtones*, or *gems*, in the general, ſee below. The origin and formation of *precious ſtones*, ſee STONE. For the art of engraving on *precious ſtones*, ſee ENGRAVING. The art of cutting them, ſee LAPIDARY. Modern work of *precious ſtones*, ſee MOSAIC.

Pearls are alſo ranked among *gems*, though not ſtones.

Gems are ſometimes found of regular ſhapes with a natural polith, after the beds of rivers, after great rains, and theſe are of the pebble kind; and ſometimes of irregular ſhapes, with a rough coat, in mines, and the clefts of rocks. Thoſe of the firſt ſort are the *gems*, on which the ancients engraved, and which are commonly called intaglios; theſe are uſually of a long oval figure inclining to a point at each end, convex as well upon the engraved ſurface as on the others, and having a ridge running from end to end on the under ſide, which is thereby as it were divided into two faces; both which are alſo, though not ſo ſtrikingly, parted from the upper face by another ridge running quite round the oval. The ſtone moſt frequently engraved on, is what the jewellers call the beryl, a ſtone very different from that called the beryl by the ancients, which was the *gem* we call the aquamarine.

This beryl of the jewellers is only a finer kind of cornelian, and is of three kinds; the red, the yellow, and the white. The firſt is much the moſt valuable of theſe, and is of the greateſt luſtre; that which is moſt frequent next this beryl, is the *praſius*, or, as ſome call it, the *plasma de ſmeraude*. This one jewellers call the prime or prime emerald. It is of a ſomewhat dusky green, and is ſometimes tolerably clear, but moſt uſually it is full of black and white ſpecks, and rather opake.

The moſt frequent next to this is the jacinth or hyacinth. This alſo is not the *gem* known by the ancients under this name, that having been a ſort of amethyſt; but the ſtone we now call the hyacinth, which is of a tawny red, or a ſort of fire-colour, and is very bright and tranſparent. The chryſolite is ſometimes, but rarely, found engraved on. It is of a greeniſh colour, and is tranſparent, but not lively. Sometimes we alſo meet with the oriental pebble cryſtal, which is much more tranſparent and lively than the common cryſtal, and indeed but little inferior in beauty to the white ſapphire; the garnet, which is of a deep red, and not ſo lively as the hyacinth; and, finally the amethyſt, which is of a deep purple, and is very lively and tranſparent. Theſe ſtones have been all the ſtones uſed in the earlier times of the Roman empire. There are, indeed, ſometimes found ſome other ſpecies; but theſe are rarely of any time but the later ages of the empire, when the art itſelf was greatly upon the decline. The before mentioned ſtones are ſaid to have been brought to Rome from the borders of the Nile, or of the Ganges. The onyx agate, ſardy-ſardonyx, and alabaſter of two colours, were alſo engraved on by the Romans in a different manner. Theſe, as alſo certain ſhells of different coats, were frequently engraved in relief, and theſe ſorts of engravings are commonly called cameos; they alſo ſometimes engraved a head, or ſome other figure, in relief of gold upon a blood-ſtone.

Beſide theſe there are alſo ſome antiques, moſtly cornelians, which are covered with a ſtratum of white. This ſtratum has by ſome been looked on as natural, but it was really only a ſort of coat or cruſt that was laid on: this was uſed only in the times of the lower empire. The ancients engraved many of their ſtones juſt as they were found with their native polith, and in their native ſhape; but the beauty of the ſeveral ſpecies of the onyx could only be ſhewn by a proper cutting. The antique *gems* of Greek work are of all others the moſt eſteemed, and next to them the Roman, in the time of the higher empire. Phil. Tranſ. N° 183. or vol. xiv. p. 502, &c. Several authors, both ancient and modern, relate wonders of the virtues and medicinal properties of *gems*; but their reputation, in this reſpect, is now a little fallen; and many even deny them any virtue at all: yet are the fragments of ſuch ſtones ſtill preſerved by ſome phyſicians in ſome of the moſt celebrated compoſitions; and there are ſeveral chemical preparations made of them.

In reality, as ſeveral perſons of the greateſt candour and experience have related ſome conſiderable effects of certain *gems*, on their own particular obſervations; and it is no way improbable, that ſome of the later ſtones may have conſiderable operations on the human body, it might be improper raſhly and haſtily to exclude from them any medicinal virtues at all.

When much the greateſt part of their traditionary qualities is yet found to be fabulous, there will ſtill remain ſtones, on as real and well-warranted a footing as many of our other medicines.

On ſuch conſiderations, Mr. Boyle was induced to give us a treatiſe of the Origin and Virtues of Gems; the purport whereof is to ſhew that ſuch ſtones were originally in a fluid ſtate, or made up of ſuch ſubſtances as were formerly fluid; and that many of their general virtues are probably derived from the mixture of metalline and other mineral ſubſtances uſually incorporated with them; while the great variety, and the particular efficacy of their virtues, ariſe from ſome happy concurrent circumſtances of that commixture; e. gr. the peculiar nature of the impregnating liquor, the proportion wherein it is mixed with the petrolcent juice, and the like.

To ſupport this hypotheſis of the ſtones of *gems*, he ſhews, that ſeveral of them are not ſimple concretions of any petrolcent liquors; but that they conſiſt alſo, of other mineral adventitious parts; which he argues, from the ſeparableneſs of ſuch ſubſtances in ſome ſtones, the ſpecific gravity in others, and the different waters, or tinctures to be met with in *gems* of the ſame ſpecies; as rubies, ſapphires, granates, and even diamonds; of which ſome are yellow, ſome of other colours, and ſome green, almoſt like emeralds.

There may, therefore, be in ſome *gems* numberleſs adventitious corpuſcles; but there is great reaſon to think that ſome of theſe corpuſcles may be imbued with ſeveral properties, and medicinal virtues. There is a great difference among thoſe impregnating particles; and, probably, a greater variety than known by us; and, laſtly, many *gems* are very richly impregnated with theſe particles; why, then, may not they exert ſome power? This is the ſubſtance of what is directly alledged in behalf of *gems*.

The ſtreſs of what is objected againſt them is, that the mineral ſubſtances they contain, are ſo cloſely locked up, that they can communicate nothing to the body, and ſo can have no medicinal operation, being unconquerable by ſo ſmall a heat as that of the ſtomach, and other parts of the body.

This objection might be plauſible enough to prevent one's aſcribing any medicinal virtues to thoſe *gems*; but can conclude nothing againſt what is warranted by ſo many facts and obſervations; eſpecially when there are ſeveral particulars that obviate this objection.

For a vigorous fermentation, though frequently baſtler than many *gems*, is known to emit copious effluvia; and there are many which have been found to have a manifeſt and conſiderable operation on the human body, by being worn in the pocket, or long held in the hand. Mr. Boyle has found divers tranſparent pebbles, which, when cut would reſemble diamonds, that might be immediately brought to emit copious and ſtrong ſcented ſteams; and if electrical attractions be owing to the effluvia of bodies excited by rubbing, very ſlight operations may ſuffice to procure exſpirations from tranſparent *gems*, many of which are electrical, and even the hardeſt of all, viz. diamonds; one of which Mr. Boyle kept by him, which, upon a little friction, would attract very vigorouſly.

To that part of the objection which pretends *gems* not to be diſſipable by the heat of the ſtomach, it may be replied that we do not know how far the digeſtion of things in the ſtomach is owing to heat; nor is it proved, that ſuch materials can have no operation on the body, without being digeſted, i. e. in paſſing through it, without undergoing any ſenſible change of bulk, figure, &c. as *gems*, when ſwallowed, are ſuppoſed to do.

For ſome chemiſts make a kind of bullets of regulus of antimony, which they call *pilulæ perpetuæ*; becauſe, when they have performed their operation in the body, and are caſt forth with the excrements, they may be uſed again and again, for the ſame purpoſe; nor do we know what analogy there may be between ſome juices in the body, and thoſe mineral parts which impregnate *gems*. For though the *ocellus mundi* be reckoned among the rare *gems*; yet, if one of the beſt ſort be, for a while, kept in common water, it will undergo an alteration obvious to the eye.

Add, that Mr. Boyle has, without heat, obtained a manifeſt tincture from ſeveral hard bodies, and even from a tranſparent ſort of *gem*, by means of a faint liquor diſtilled from a vegetable ſubſtance, as harmleſs, and as plentifully eaten, as bread; and whether ſome juices of the body, aſſiſted by the natural heat thereof, may not ſerve

for menſtruus to ſome *gems*, we will not ſay: but even the natural heat of a human ſtomach, and, perhaps, of the external parts of the body, may be ſuſficient, though not to diſſolve precious ſtones, yet to ſoften our ſome of their ſubſtances: for it is certain, it makes a ſenſible alteration in the hardeſt ſort of them. Witneſs a diamond of Mr. Boyle's, whoſe electrical faculty might be exerted, without rubbing, only by a laugnid degree of adventitious heat; and another, which, by means of water made a little more than lukewarm, might be brought to ſhine in the dark. See PHOSPHORUS. Boyle's Works abridged. vol. i. p. 62.

Laſtly, it is to be yet objected, that it is not likely *gems* ſhould part with any effluvia, or portions of themſelves, inaſmuch as they loſe none of their weight: it may be anſwered, that the antimonial glaſs and cup imbue wine, and other liquors, with a ſtrong emetic quality, without undergoing any ſenſible diminution of weight. Add, that though common water be not allowed a menſtruum fit to draw any thing from mercury; yet both Helmont, and others, inform us, that a large quantity of it, being kept a day, or two, upon a ſmall proportion of that drug, will acquire a virtue of killing worms, though the mercury retains its former weight.

GEMS, *imitation of antique*. There has been at different times a method practiſed by particular perſons of taking the impreſſions and figures of antique *gems*, with their engravings, in glaſs of the colour of the original *gem*. This has always been eſteemed a very valuable method, and greatly preferable to the more ordinary ones of doing it on ſealing-wax or brimſtone; but, to the misfortune of the world, this art being a ſecret only in the hands of ſome particular perſons, who got their bread by it, died with them, and every new artiſt was obliged to new invent the method, till at length Mr. Homberg, having found it in great perfection, gave the whole proceſs to the world to be no more forgotten or loſt, and ſince that time it has been very commonly practiſed in France, and ſometimes in other places.

Mr. Homberg was favoured in his attempts with all the engraved *gems* of the king's cabinet, and took ſuch elegant impreſſions, and made ſuch exact reſemblances of the originals, and that in glaſſes ſo artfully tinged to the colour of the *gems* themſelves, that the neceſt judges were deceived in them, and often took them for the true antique ſtones. Theſe counterfeit *gems* will ſerve as well as the original ones, to make more copies from afterwards; ſo that there is no end of the numbers that may be made from one; and there is this farther advantage, that the copy may be eaſily made perfect, though the original ſhould not be ſo, but ſhould have ſuſtained ſome damage from a blow or otherwiſe. Mem. Acad. Par. 1712.

The great care in the operation is to take the impreſſion of the *gem* in a very fine earth, and to preſs down upon this a piece of proper glaſs, ſoftened or half melted at the fire, ſo that the figures of the impreſſion made in the earth may be nicely and perfectly expreſſed upon the glaſs. In general, the whole proceſs much reſembles that of the common founders. But when it is brought to the trial, there is found a number of difficulties which were not to be foreſeen, and which would not at all affect the common works of the founder. For his purpoſe every earth will ſerve, that is fine enough to receive the impreſſion, and tough enough not to crack in the drying: theſe all ſerve for their uſe, becauſe their metals which they call ore of a nature incapable of mixing with earth, or receiving it into them, even if both are melted together, ſo that the metal always eaſily and perfectly ſeparates itſelf from the mould; but it is very difficult in theſe caſes of glaſs. They are compoſed of a matter which differs in nothing from that of the mould, but that it has been run into this form by the force of fire and the other has not yet been ſo run; but is on any occaſion ready to be ſo run, and will mix itſelf inſeparably with the glaſs in a large fire; and, conſequently, if there be not great care uſed, as well in the choice of the glaſs as in the manner of uſing it, when the whole is finiſhed, there will be found great difficulty in the ſeparating the glaſs from the mould, and often this cannot be done without wholly deſtroying the impreſſion.

All earths run more or leſs eaſily in the fire, as they are more or leſs mixed with ſaline particles in their natural formation. As all ſalts make earths run into glaſs, and as it is neceſſary to uſe an earth on this occaſion for the making a mould, it being alſo neceſſary to the perfection of the experiment, that this earth ſhould not melt or run, it is our buſineſs to ſearch out for this purpoſe ſome earth which naturally contains very little ſalt. Of all the ſpecies of earth which Mr. Homberg examined on this occaſion, none proved ſo much diveſted of ſalts, or ſo fit for the purpoſe, as the common tripela, or tripoli, uſed to poliſh glaſs and ſtones. Of this earth there are two common kinds, the one reddiſh, and compoſed of ſeveral flakes or ſtrata; the other yellowiſh, and of a ſimple ſtructure. Theſe are both to be had in the ſhops. The latter kind is from the Levant, and the former is found in England, France, and many other places. This tripela muſt be choſen loft and ſmooth to the touch, and not mixed with ſandy or other extraneous matter. The yellowiſh kind is the beſt of the two, and is commonly called Venetian tripoli. This receives the impreſſions very beautifully, and never mixes with the glaſs in the operation, which the red kind ſometimes does. Mr. Homberg uſually employed both kinds at once in the following manner; firſt, powder a quantity of the red tripela on an iron mortar, and ſifting it through a fine ſieve, let it by for uſe; then ſcrape with a knife a quantity of the yellow tripela into a pot of powder, and afterwards run it till very fine in a glaſs mortar with a glaſs peſtle. The finer this powder is, the finer will be the impreſſion, and the more accurately perfect the caſt. The artificer might naturally ſuppoſe, that the beſt method to obtain a perfect fine powder of this earth, would be by waſhing it in water; but he muſt be cautioned againſt this. There is naturally in this yellow tripoli a ſort of unctuoſity, which when it is formed into a mould keeps its granules together, and gives the whole an uniform glaſſy ſurface: now the waſhing the powder takes away this unctuoſity, and though it render it much finer, it makes it leave a granulated ſurface, not this ſmooth one in the mould, and this muſt render the ſurface of the caſt leſs ſmooth.

When the two tripelas are thus ſeparately powdered, the red kind muſt be mixed with ſo much water as will bring it to the conſiſtence of paſte, ſo that it may be moulded like a lump of dough between the fingers: this paſte muſt be put into a ſmall crucible of a flat ſhape, and about half an inch or a little more in depth, and of ſuch a breadth at the ſurface as is a little more than that of the ſtone whoſe impreſſion is to be taken. This crucible is to be nicely filled with this paſte, lightly preſſed down into it, and the ſurface of the paſte muſt be ſtrewed over with the fine powder of the yellow tripela not wetted. When this is done, the ſtone, whoſe impreſſion is to be taken, muſt be laid upon the ſurface, and preſſed evenly down into the paſte with a finger and thumb, ſo as to make it give a ſtrong and perfect impreſſion: the tripela is then to be preſſed nicely even to its ſides with the fingers, or with an ivory knife: the ſtone muſt be thus left a few moments, for the humidity of the paſte to imbibe the dry powder of the yellow tripela which is ſtrewed over it; then the ſtone is to be carefully raiſed by the point of a needle fixed in a handle of wood, and the crucible being then turned bottom upwards, it will fall out, and the impreſſion will remain very beautifully on the tripela.

If the ſides of the cavity have been injured in the falling out of the ſtone, they may be repaired, and the crucible muſt then be let, for the paſte to dry, in a place where it will not be incommoded by the duſt.

The red tripoli being the more common and the cheaper kind, is here made to fill the crucible only to ſave the other, which alone is the ſubſtance fit for taking the impreſſion. When the ſtone is taken out, it muſt be examined, to ſee whether any thing be lodged in any part of the engraving, becauſe if there be any of the tripela left there, then will certainly be to much wanting in the impreſſion. When the crucible and paſte are dry, a piece of glaſs muſt be choſen of a proper colour, and cut to a ſize proper for the figure; this muſt be laid over the mould, but in ſuch a manner that it does not touch the figures, otherwiſe it would ſpoil them. The crucible is then to be brought near the ſurface by degrees, and gradually heated till it cannot be touched without burning the fingers; then it is to be placed in the furnace under a muffle, ſurrounded with charcoal. Several of theſe ſmall crucibles may be placed under one muffle, and when they are properly diſpoſed, the aperture of the muffle ſhould have a large piece of burning charcoal put to it, and then the operator is to watch the proceſs, and ſee when the glaſs begins to look bright; this is the ſignal of its being fit to receive the impreſſion. The crucible is then to be taken out of the fire, and the hot glaſs muſt be preſſed down upon the mould with an iron inſtrument to make it receive the regular impreſſion: as ſoon as this is done, the crucible is to be ſet at the ſide of the furnace out of the way of the wind, that it may cool gradually without breaking. When it is cold, the glaſs is to be taken out, and its edges ſhould be grated round with pincers, which will prevent its flying afterwards, which is an accident that ſometimes happens when this caution has been omitted, eſpecially when the glaſs is naturally tender. The different coloured glaſſes are of different degrees

degrees of hardness, according to their compositions, but the hardest to melt are always the best for this purpose, and this is known by a few trials.

If it be desired to copy a stone in relief, which is naturally in creux; or to take one in creux, which is naturally in relief; there need no more than to take an impression first in wax or sulphur, and to mould that upon the paste of crystal instead of the stone itself: then proceeding in the manner before directed, the proofs will have the desired success. *Mem. Acad. Par.* 1713.

GEM, *Indian*, *India gemma*, a name given by Pliny, and some other of the ancients, to a pearl of a reddish colour, which, according to their accounts, afforded a purple fit to vie with rubbish: another kind of it is also mentioned, which was white and looked dully.

GEMARA, or GHEMASA, the second part of the TALMUD.

The word גמרא, *gemara*, is commonly supposed to denote a supplement; but it rather signifies complement, perfection; being formed of the Chaldee גמר, *gamar*, *to finish*, *perfect*, or *complete* any thing.

The rabbins call the Pentateuch, simply, the law. The first part of the Talmud, which is only an explication of that law, or an application thereof to particular cases, with the decisions of the ancient rabbins thereon, they call the MISCHNA, i. e. second law: and the second part, which is a more extensive and ample explication of the same law, and a collection of decisions of the rabbins posterior to the Mischna, they call *Gemara*, q. d. perfection, completion, finishing; because they esteem it the finishing of the law, or an explication, beyond which there is nothing further to be desired.

The *Gemara* is usually called, simply, Talmud, the common name of the whole work. In this sense we say, there are two Gemaras, or Talmuds; that of Jerusalem, and that of Babylon: though, in strictness, the *Gemara* is only an explication of the Mischna, given by the Jewish doctors in their schools; much as the commentaries of our school divines on St. Thomas, or the master of the sentences, are an explication of the writings of those authors.

A commentary, Monsr. Tillemont observes, was wrote on the Mischna, by one Jochanan, whom the Jews place about the end of the second century: but Fa. Morin proves, from the work itself, wherein mention is made of the Turks, that it was not wrote till the time of Heraclius, or about the year 620; and this is what is called the *Gemara*, or Talmud of Jerusalem, which the Jews do not use or esteem much, because of its obscurity.

They set a much greater value on the *Gemara*, or Talmud of Babylon, begun by one Asa, discontinued for seventy-three years, on occasion of the wars with the Saracens and Persians; and finished by one Jose, about the close of the seventh century. See TALMUD.

Though the name Talmud, in its latitude, includes both the Mischna, and the two *Gemaras*; yet it is properly that of Asa and Jose, alone, which is meant under that name.

The Jews prize above all these other writings, and even set it on a level with scripture itself, as edicts they conceive it as the word of God, dictated by tradition from Moses, and preserved, without interruption to their time. R. Jehudah, and afterwards R. Jochanan, R. Asi and R. Josa, fearing the traditions should be lost in the dispersion of the Jews, collected them into the Mischna and the *Gemara*. See CARAITES and RABBINISTS.

GEMATRIA, or GAMETRIA, the first kind of artificial CABBALA used by the Jews.

The words is formed from the rabbinical Hebrew גימטריא, formed by corruption of the Greek.

Gematria is a geometrical or arithmetical method of explaining words, wherein there are two kinds; the first bearing a more immediate relation to arithmetic, and the latter to geometry.

The first consists in taking the numerical value of each letter in a word or phrase, and giving it the sense of some other word, whose numerical letters, taken after the same manner, make the same sum. For it is to be observed, that neither the Hebrews, nor the Greeks, have any numerical figures besides the letters of the alphabet.

Thus, a cabbalist, taking the two first words in Genesis, בראשית ברא, and by addition getting the sum total of all the numbers, signified by those letters, finds that these two words signify the same as those other three השמה בראו ראש. For, as to the first, ב is 2, ר, 200; א, 1; ש, 300; י, 10; ת, 400; ב, 2; ר, 200; and א, 1; which, together, make 1116. And, as to the latter, ב figures 2; ר, 200; א, 1; ש, 300; ת, 400; ב, 2; ר, 200; and ש, 300; ה, 5; ש, 300; מ, 40; ה, 5; ב, 2; ר, 200; and א, 1: which, summed up, yield the same number 1116.

Whence the cabbalist concludes, בראשית ברא, *in the beginning he created*, signifies the same thing as השמה ובראו ראש, *it was created at the beginning of the year*; and, accordingly, the received opinion of the cabbalists is, that the world was created at the beginning of the month Tisri, which was anciently the first month in the year, and answers to our first month in autumn, viz. September.

So, again, in the prophecy of Jacob, Gen. xlix. 10. the words שילה כי יבא, are unpointed of the Messiah, because they make the same number with משיח, which signifies the Messiah. The second kind of *gematria* is much more obscure and difficult; and, accordingly, is less used. It is employed in seeking for shibrals and hidden interpretations in the dimensions and parts of the buildings mentioned in scripture, by dividing, multiplying, &c. those measures by each other. Of this we shall give an example from some Christian cabbalists.

The scripture says, that Noah's ark was 300 cubits long, 50 wide, and 30 high: now the cabbalist takes the length for the basis of his operations; 300, in the Hebrew, is expressed by the letter ש, which, length divided by the height 30, gives the quotient 10, the Hebrew character whereof is י; this is to be placed on the right side of ש: he then divides the same length by the width, 50, the quotient whereof, 6, is expressed by a ו, which, being placed on the left side of ש, makes, together with the other two letters, the name *Jesus*, ישו. Thus, by the rules of the cabbala, it appears, that there is no salvation but in Jesus Christ; or, at the deluge, no person was saved but those in the ark.

After the like manner is the same name ישו found in the dimensions of Solomon's temple. But it is rather an injury than an advantage to the Christian religion, to support it by such frivolous evidences.

GEMELLES, in *Heraldry*, a bearing of bars by pairs, or in couples, in a coat of arms. He beareth gules on a chevron argent, three BARS *gemelles* sable, by the name of Throgmorton.

GEMELLUS, in *Anatomy*, a muscle of the arm, called also BICEPS *externus*, as having two heads. See *Tab. Anat. Myol.* fig. 1. n. 26. fig. 6. n. 14. fig. 7. n. 13. 13. 13.

One of the heads of this muscle rises tendinous from the upper part of the inferior costa of the scapula; whence passing between the muscles to the back part of the humerus, it joins the other head, and both run together to their insertion at the ancon or tip of the elbow. The *gemelli* is the first extensor of the cubit, and is by many reckoned two distinct muscles; the first called *longus*, the latter *brevis*.

GEMINATED *column*. See COLUMN.

GEMINI, in *Astronomy*, the THIRD CONSTELLATION, or SIGN of the zodiac, the third in order, representing Castor and Pollux; and it is marked thus, ♊.

The stars in the sign *Gemini*, in Ptolemy's catalogue, are 25; in Tycho's, 25; in Hevelius's, 38; in the Britannic Catalogue, 85. The order, names, longitudes, latitudes, magnitudes, &c. whereof, are as follow:

Names and situation of the stars.		Longitud.			Latitude.			Magnitude

GEMINI, in *Anatomy*, two muscles of the thigh, which arise from the protuberance of the ischium, and are inserted with the psoas muscle into the dent at the root of the great trochanter.

These are called *gemelli* by Winslow. The superior or smaller *gemellus* is fixed to the lower part of the spine of the os ischium, to the superior part of the small ischiatic notch, and to a rough line which runs cross the outside of the ischium, beginning at the spine, and continues under the acetabulum, where it is bent downward.

The inferior and largest *gemellus* is fixed to the superior and back part of the tuberosity of the ischium, and to a rough impression, which runs cross the outside of the ischium, from the lower extremity of the ischiatic notch and it bends upward towards the other line, together with which it forms most of the greater semi-circle. Both these muscles have also a small insertion in the inside of the ischium, where being united together by a particular membrane, one of them joins the upper side, and the other the lower side of the *obturator internus*, a little after it has passed over the notch. They include it as in a bag, and continue to be fixed to it by fleshy fibres all the way to its extremity. The superior muscle terminates wholly with the tendon of the *obturator internus*; but the inferior, being broader, is inserted likewise by fleshy fibres in the orbicular ligament, and under the tendon of the same obturator. Winslow's Anat. p. 210.

GEMMA. See GEM.

GEMMA, *sal*, is peculiarly used for *rock* SALT, or salt dug out of mines.

The name *gemma* is applied to this on occasion of its hardness and brilliancy, which is not unlike that of chrystal. The principal mines of this salt are those of Wielica, in Poland; those of Epernis, in Upper Hungary; and those of Cardona, in Catalonia.

The chief use of this salt is for the powdering or pickling of meats, in places destitute of salt springs, &c.

GEMMA, or GEM, among old *Botanists*, the turgid bud of a vine, or other tree, when it is beginning to bear; called also *nodus*, *&c.*

Gemma est in qua virtus vitæ latendi. Cic. de Senectute, cap. 15.

GEMMA *Veneris*, in *Natural History*, a name given by some of the Latin poets, and other authors in that language, to a *gem*, which was much esteemed by the Romans, and fet in rings. It was called by the Greeks *Aphrodites*. Many have fuppofed that to be the opal: but it is certain from the older accounts, that the moft beautiful kind of the amethyft was the gem they called by this name. They diftinguifhed the amethyft, as all the other *gems*, into feveral kinds, according to the degrees of the colour; and to the moft eminent of thefe they gave peculiar names, as is evident in the feveral kinds of the emerald and beryl. The world amethyfts were thofe which had very little colour beyond that of cryftal, and the very beft were thofe which had the fine red of the carbuncle, mixed with the purple of the violet, and the whole fo pale, that a rofe-colour feemed blended with them, and predominating over the reft. Thefe, Pliny tells us, were called *pædarotes* and *anterotes*, and were the *gems* called, from their beauty, *Aphrodites lapis* and *gemma Veneris*; but all thefe names have been fince given by others to the opal.

GEMEUM, an epithet ufed by the Latins to expreſs fuch veſſels as were called *cratera* and *nicteris* by the Greeks. The more correct Roman authors, however, call this *gemmatum poculum*, and not *gemmeum*; the word *gemmeum* fignifying properly a vafe or cup, cut out of a ſingle ſtone, as an agate, or the like; but *gemmatum* expreſſing thofe fine vafes of gold, which were ornamented with emeralds and other precious ſtones.

GEMONIÆ *ſcalæ*, or *gradus* GEMONII, among the *Romans*, was much the ſame as a gallows, or gibbet, in England.

Some ſay, they were thus denominated from the perſon who raiſed them; others, from the firſt criminals that ſuffered on them; and others, from the verb *gemo*, *I ſigh or groan*.

The *gradus gemonii*, according to Publius Victor, or Sextus Ruſus, was a place raiſed on ſeveral ſteps, from whence they precipitated their criminals: others repreſent it as a place whereon offenders were executed, and afterwards expoſed to public view. The *gemoniæ ſcalæ* were in the tenth region of the city, near the temple of Juno. Camillus firſt appropriated the place to this uſe, in the year of Rome 358.

GEMONIDES, a name by which ſome of the ancients have called the præficæ; probably the ſame with our ſhalachtes, a ſtone famous with them for its ſuppoſed virtue in promoting delivery.

GEMOTE, or GEMOT, *convention*, a Saxon word, denoting a meeting or aſſembly.

Comitia tame parvum habent omnia ad gemotum & rythma ab gemoto, nifi gratiam ſur fuerit. LL. Ed. Conf. See WITTENA.

GEMURSA, a word uſed by the ancient writers on *Medicine*, for a diſtemper which was an exereſcence of fleſh between the toes, a diſeaſe not known with us.

GENA. See CHEEK.

GENÆ *quadratæ*. See QUADRATUS.

GENDARMES, or GENS D'ARMES, q. d. men of arms, a term uſed among the French for a ſelect body of horſeguards: becauſe they ſucceeded the ancient men of arms, who were armed at all points, and thence were called *gendarmes*.

At preſent, the troops of the king's guard de corps, the muſqueteers, and light-horſe, are reputed to belong to the gendarmerie.

The *grand-gendarmes*, ſometimes called ſimply the *gendarmes*, are a troop of gentlemen, to the number of about

about 200, and in time of war 240, who guard the king's person. The king himself is their captain, and one of the prime peers the captain-lieutenant, under whom are two sub-lieutenants, three cuffigns, and three guidons. When the king marches with all his houshold troops, the *gens d'armes* clole the march. They were eſtabliſhed about the year 1665.

Their device is a thunder-bolt falling from heaven, with the motto, *Non ſunt inane Jovis*. There are alſo, beſide theſe, *gens d'armes* of the queen, the dauphin, &c.

The *gendarmery*, at preſent, is a body of horſe, conſiſting of fifteen companies, forming eight ſquadrons, viz. the Scotch *gendarmes*, the Engliſh *gendarmes*, the Burgundy *gendarmes*, and the Femiſh *gendarmes*, which four companies compoſe the king's *gens d'armes*, or life-guard. The other companies take their names from the princes who command them as captains, viz. the queen's *gendarmes*, the queen's light horſe; the dauphin's *gendarmes*, the dauphin's light horſe; the duke of Burgundy's *gendarmes*, the duke of Burgundy's light-horſe; the duke of Orleans's *gendarmes*, &c. vacktrooms, at a medium, conſiſts of twenty-ſix *gendarmes*, or light horſe. Each company is divided into two brigades, one commanded by the captain-lieutenant, and the other by the ſub-lieutenant; and the ſubordinate officers are an enſign and guidon.

GENDER, GENUS, in *Mineralogy*. See GENUS.

GENDER, in *Grammar*, denotes a diviſion or diſtinction of nouns, or names, according to the different ſexes of the things they denote.

It has been thought proper, in order to render diſcourſe more expreſs and diſtinct, as alſo to embelliſh it by a variety of terminations, to conceive certain diverſities in adjectives, accommodated to the ſubſtantives they are applied to; whence, from a regard to that notable difference there is between the two ſexes, all nouns ſubſtantives have been diſtinguiſhed into maſculine and feminine; and the nouns adjectives alſo varied to correſpond therewith.

Mr. Harris obſerves, that in the diſtribution of *genders*, ſuch ſubſtantives might have been conſidered as maſculine, which were conſpicuous for the attributes of imparting and communicating; or which were, by nature, active, ſtrong, and efficacious, and that indiſcriminately whether to good or ill; or which had claim to eminence, either laudable or otherwiſe: the feminine, on the contrary, were ſuch as were conſpicuous for the attributes either of receiving, of containing, or of producing and bringing forth; or which had more of the paſſive in their nature than of the active; or which were peculiarly beautiful and amiable; or which had reſpect to ſuch exerciſes as were rather feminine than maſculine. Thus the ſun, the ſky, time, death, God, &c. are maſculine; but the moon, the earth, a ſhip, a city, country, virtue, fortune, &c. are feminine. Hermes, p. 44, &c.

But as there are an infinity of words, which had no proper relation, either to the one ſex, or the other, they had *genders* aſſigned them, rather out of caprice than reaſon; and hence it is that the *gender* of a noun is frequently dubious and fluctuating. Though, as there are ſubſtantives, that have evidently no ſex, the neuter *gender* expreſſing ſuch ſubſtances as are natural and rational a diſtinction as either of the others.

It ſhould here, however, be obſerved, that this inſtitution of *genders* was not made with deſign and deliberation by the maſters of language, but was introduced by cuſtom and uſage. At firſt, there was only a difference between the names of animals, when ſpoke of males and females; and, by degrees, the ſame regulation was extended to other things: the grammarians have only noted and allowed what uſage had eſtabliſhed. The oriental languages frequently neglect the uſe of *genders*; and the Perſian language has abſolutely none at all, which is no diſadvantage; the diſtinction of *genders* being in great meaſure uſeleſs.

The Latins, Greeks, &c. generally content themſelves to expreſs the different *genders* by different terminations, as *bonus equus*, a *good horſe*, *bona equa*, a *good mare*, &c. But in Engliſh we frequently go further, and expreſs the difference of ſex by different words; as *boar*, *ſow*; *boy*, *girl*; *buck*, *doe*; *bull*, *cow*; *cock*, *hen*; *dog*, *bitch*, &c.

We have only about twenty-four feminines, diſtinguiſhed from the males, by the variation of the termination of the male into *eſs*; of which number are *abbot*, *abbeſs*; *count*, *counteſs*; *actor*, *actreſs*; *heir*, *heireſs*; *prince*, *princeſs*, &c. which is all that our language knows of any thing like *genders*.

The eaſtern languages, as well as the vulgar languages of the Weſt, have three *genders*; the maſculine, feminine, and neuter. The Greek and Latin have likewiſe the neuter, common, and the doubtful *gender*; and beſides theſe, they have the epicene, or promiſcuous, which under one ſingle *gender*, and termination, includes both the kinds.

The Engliſh language, with ſingular propriety, following nature alone, applies the diſtinction of maſculine and feminine only to the names of animals; all the reſt are neuter; except when by a poetical or rhetorical figure, things inanimate and qualities are exhibited as perſons, and conſequently become either male or female. And this gives the Engliſh an advantage above moſt other languages in the poetical and rhetorical ſtyle; for when nouns naturally neuter are converted into maſculine or feminine, the perſonification is more diſtinctly and ſenſibly marked. Lowth's Grammar, p. 44. ed. 1772.

GENDER, in *Geometry*. GEOMETRICAL *lines* are diſtinguiſhed into *genders*, or *powers*, claſſes, or orders, according to the number of the dimenſions of the equation that expreſſes the relation between their ordinates, and the abſciſſes.

GENDER, in *Botany*. } See GENUS.

GENDER, in *Aſtroſc. &c.* }

GENEALOGICA *arbor*. See ARBOR.

GENEALOGY, a ſeries or ſucceſſion of anceſtors, or progenitors; or a ſummary account of the relations and kindred of a perſon, or family, both in the direct and collateral lines.

The word is Greek, *γενεαλογια*, which is formed of *γενεα*, *genus*, *proſapia*, *race* and *λογος*, *ſermo*, *diſcourſe*.

In ſome chapters, and military orders, it is required, that the candidates produce their *genealogy*, to ſhew that they are noble by ſo many deſcents.

Genealogical table, *genealogical tree*, *genealogical ſtock*, or *ſtem*, &c. ſee ARBOR.

The *genealogical* degrees are uſually repreſented in circles, ranged over, under, and aſide of each other. The ancients had the like; which they called *ſtemmata*, from a Greek word, ſignifying *crown*, *garland*, or the like.

GENECANTHE, in *Botany*, a name uſed by ſome authors for the black henyoy.

GENERAL, ſomething that comprehends all, or extends to a whole genus, or kind.

All the ſciences have ſome general principles, or AXIOMS. *A general court*; *general* councils are particularly called OECUMENICAL.

GENERAL *officer*, *government*, *council*, *diet*, *ſeraſkil*, *food*, *geography*, *gravity*, *office*, *nature*. See the ſeveral ſubſtantives.

GENERAL *officers*, in an *army*, are thoſe who do not only command over a ſingle company, or regiment, but whoſe office and authority extend over a body of ſeveral regiments of horſe and foot.

Such are LIEUTENANT-*general*, MAJOR-*general*, *generals* of the horſe, of the foot. See GENERAL, below. See alſo PAYMASTER-*general*, COMMISSARY-*general*, MUSTER-*maſter-general*, &c. and PAY.

We have alſo officers in law, in the revenues, &c. diſtinguiſhed by the appellation of *general*: as, ATTORNEY-*general*, SOLICITOR-*general*, &c. RECEIVER-*general*, COMPTROLLER-*general*, &c.

GENERAL *words*, *qualities*, &c. See the ſubſtantives.

GENERAL *terms*, or *words*, are ſuch as expreſs or denote *general* ideas.

Ideas become *general*, by ſeparating from them the circumſtances of time, place, or any other ideas that may determine them to this or that particular exiſtence.

By this way of abſtraction they become capable of repreſenting more individuals than one; each of which having a conformity to that abſtract idea, is of that ſort.

All things, Mr. Locke obſerves, that exiſt, being particulars, it might be expected that words ſhould be ſo too in their ſignification; but we find it quite contrary; for moſt of the words that make all languages, are *general* terms.

This is the effect of *reaſon* and neceſſity: for 1. It is impoſſible that every particular thing ſhould have a diſtinct peculiar name; becauſe it is impoſſible to have diſtinct ideas of every particular thing, to retain to name with its peculiar appropriation to that idea. 2. It would be uſeleſs, unleſs all could be ſuppoſed to have the ſame ideas in their minds: for names applied to particular things, wherein one alone has the idea in his mind, could not be ſignificant, or intelligible to another, who is not acquainted with all thoſe particular things which had fallen under his notice. 3. It would be of no great uſe for the improvement of knowledge; which, though founded in particular things, enlarges itſelf by *general* views, to which things reduced into ſorts under *general* names, are properly ſubſervient.

In things, where we have occaſion to conſider and diſcourſe of individuals and particulars, we uſe proper

names; as in perſons, countries, cities, rivers, mountains, &c.

The firſt ideas children get are only particular, as thoſe of the nurſe, or mother; and the names they give them are confined to theſe individuals: afterwards obſerving that there are a great many other things in the world that reſemble them in ſhape, and other qualities, they frame an idea, which they find made many particulars no partake in: ſo that they give, with others, the name, *man*, for example. In this they make nothing new, but only leave out of the complex idea they had of Peter, James, Mary, &c. that which is peculiar to each, and retain only what is common to all. And thus they come to have a *general* name, and a *general* idea.

By the ſame method they advance to more *general* names and notions; for, obſerving ſeveral things that differ from their idea of man, and which cannot, therefore, be comprehended under that name, to agree with man in ſome certain qualities; by retaining only thoſe qualities, and uniting them into one idea, they have another more *general* idea; to which, giving a name, they make a term of a more comprehenſive extenſion.

Thus, by leaving out the ſhape, and ſome other properties ſignified by the name, *man*; and retaining only body, with life, ſenſe, and ſpontaneous motion, we form the idea ſignified by the name *animal*. After the ſame manner, the mind proceeds to body, ſubſtance, and at laſt to being, thing, and ſuch univerſal terms, which ſtand for any ideas whatſoever.

Hence we ſee the whole myſtery of genus and ſpecies is nothing but abſtract ideas, more or leſs comprehenſive, with names annexed to them: this ſhews us the reaſon why, in defining words, we make uſe of the genus; namely, to ſave the labour of enumerating the ſeveral ſimple ideas, which the next general term ſtands for.

From what has been ſaid, it is plain, that *general* and univerſal belong not to the real exiſtence of things, but are the inventions of the underſtanding, made by it for its own uſe, and concern only ſigns, either words, or ideas. *General* words do not barely ſignify one particular thing; for then they would not be *general* terms, but proper names: neither do they ſignify a plurality; for then man and men would ſignify the ſame thing; but what they ſignify is a ſort of things: and this they do, by being made ſigns of abſtract ideas in the mind, to which ideas as things exiſting are found to agree, ſo they come to be ranked under that name, or to be of that ſort.

The eſſences then of the ſorts, or ſpecies of things, are nothing but theſe abſtract ideas.

It is not denied here, that nature makes things alike, and ſo lays the foundation of this ſorting and claſſing: but the ſorts or ſpecies themſelves are the work-manſhip of human underſtanding; ſo that every diſtinct abſtract idea is a diſtinct eſſence: and the names that ſtand for ſuch diſtinct ideas, are the names of things eſſentially different. Thus oval, circle, rain, and ſnow, are eſſentially different. See this farther illuſtrated under ABSTRACTION, ESSENCE, IDEA, and SUBSTANCE.

GENERAL *words*, *marrow*, *wood*. See the ſubſtantives.

GENERAL *of an army* is the chief commanding officer; whoſe buſineſs is to regulate the march and encampment of the army; to chooſe the moſt advantageous ground in the day of battle, to diſpoſe the army, to poſt the artillery, and to ſend his orders wherever there is occaſion, by his aid-de-camps. At a ſiege he is to cauſe the place to be inveſted, to regulate the approaches and attacks, to viſit the works, and to ſend out detachments for ſecuring the convoy and for foraging. See GENERALISSIMO.

The natural qualities of a *general* ſhould be a martial genius, a ſolid judgment, a healthy robuſt conſtitution, intrepidity and preſence of mind on critical occaſions, goodneſs of heart, liberality, and birth: he ſhould alſo be of a mean age, neither too young, becauſe he would want prudence and experience, nor too old, becauſe he would want vivacity and activity. He ſhould be ſteady and uniform in his conduct, affable in his diſpoſition, and yet inflexible in maintaining the diſcipline of his army. His acquired qualities ſhould be ſecrecy, juſtice, ſobriety, temperance, knowledge of the art of war both from theory and practice, the art of commanding and of ſpeaking with preciſion; great attention in preſerving the lives and ſupplying the wants of the ſoldiers, and a conſtant ſtudy of the characters of the officers of his army, ſo that he may be capable of employing them according to their reſpective talents. His conduct appears in eſtabliſhing his magazines in the moſt convenient places; in examining the country, that he may not engage his troops too far, while he is ignorant of the means of bringing them off; in procuring ſubſiſtence for them; and in ſelecting the moſt advantageous poſts for fighting, retreating, or ſhunning a battle. His experience inſpires his army with confidence; his quality, by creating reſpect, augments his authority; his liberality enables him to procure intelligence of the ſtrength and deſigns of the enemy, and thus to take the moſt ſucceſsful meaſures. In a word a *general* ought to be fond of glory, to have an averſion to flattery, to render himſelf beloved, and to keep a ſtrict diſcipline and ſubordination.

GENERAL *of the artillery*. See ORDNANCE.

GENERAL *of horſe* is an officer next under the chief *general*, who has an abſolute command of the horſe of an army, above the *lieutenant-general*.

GENERAL *of foot* is an officer under the chief *general*, who has an abſolute command of the foot of the army.

GENERAL, *adjutant*, is an officer who attends the *general*, aſſiſts in council, and carries the *general*'s orders to the army. He diſtributes the daily orders to the majors of brigade. He is likewiſe charged with the general detail of the duty of the army. The majors of brigade lend every morning to the adjutant-*general* an exact return, by battalion and company, of the men of their brigade. In a day of battle the adjutant-*general* ſees the infantry drawn up; after which he places himſelf by the *general*, to receive any orders which may regard the corps of which he has the detail. In a ſiege, he orders the number of workmen required, and ſigns the warrants for their payment. He receives the guards of the trenches at their rendezvous, and examines their condition; he gives and ſigns all orders for parties; he has an orderly ſerjeant from each brigade of infantry in the line, to carry ſuch orders as he may have occaſion to ſend from the *general*.

GENERAL is alſo uſed, in a monaſtic ſenſe, for the chief of an order; or of all the houſes or congregations eſtabliſhed under the ſame rule.

Thus we ſay, the *general* of the Ciſtercians, the Franciſcans, &c.

F. Thomaſſin derives the origin of *generals* of orders from the privileges granted by the ancient patriarchs to the monaſteries ſituate in their capital cities. By ſuch means they were exempted from the juriſdiction of the biſhop, and immediately ſubjected to that of the patriarch alone.

GENERAL *of the Jeſuits*. See JESUITS, and ADJUTANT.

GENERAL is alſo uſed, in the *Military Art*, for a particular march, or beat of DRUM; being the firſt which gives notice, commonly in the morning early, for the infantry to be in readineſs to march.

GENERALISSIMO, called alſo *Captain*-GENERAL, and ſimply GENERAL, is an officer, who commands all the military powers of a nation; who gives orders to all the other general officers; and receives no orders himſelf but from the king.

Mont. Bulzac obſerves, that the cardinal de Richelieu firſt coined this word, of his own abſolute authority, upon his going to command the French army in Italy.

GENERATED, or GENITED, is uſed, by ſome mathematical writers, for whatever is produced, either in arithmetic, by the multiplication, diviſion, or extraction of roots; or in geometry, by the invention of the contents, areas, and ſides; or of extreme and mean proportionals, without arithmetical addition and ſubtraction.

GENERATING *line*, or *figure*, in *Geometry*, is that which by its motion or revolution, produces any other figure, plane, or ſolid. See GENESIS.

GENERATION, in *Phyſics*, denotes the act of procreating, or producing a thing which before was not: or, the total change or converſion of a body into a new one, which retains no ſenſible part or mark, of its former ſtate.

Thus, fire is ſaid to be *generated*, when we perceive it to be where before was only wood, or other fuel; or when the wood is ſo changed, as to retain no ſenſible character of wood: thus, alſo, a chick is ſaid to be *generated*, when we perceive the chick, where before was only an egg; or when the egg is changed into the form of a chick.

In *generation*, there is not properly any production of new parts, but only a new modification or manner of exiſtence of the old ones; by this, *generation* is diſtinguiſhed from *creation*.

It is diſtinguiſhed from *alteration*, in that the ſubject, in this latter, remains apparently the ſame; and only the accidents, or affections, are changed: as when the ſame body is to day well, and to-morrow ſick; or that bread, which before was round, is now ſquare.

Laſtly, *generation* ſtands oppoſed to *corruption*, which is the utter extinction of a former thing: as, when that which before was wood, or an egg, is no longer the one or the other; whence it appears that the *generation* of one thing is the corruption of another.

The Peripatetics explain *generation* by a change or paſſage from a privation, or want of a ſubſtantial form, to the having of ſuch a form. The moderns allow of no other change in *generation*, than what is local: according to them, it is only a tranſpoſition, or new arrangement of parts;

parts; and thus the same matter shall successively undergo an infinity of *generations*.

A grain of wheat, e. gr. is committed to the ground: this, imbibing the humidity of the soil, becomes turgid, and dilates to such a degree, that it becomes a plant; and, by a continual accession of matter, ripens by degrees into an ear, and at length into new seed. This seed ground in the mill, appears in form of flour; which mixed up with water, makes a paste, whereof, with the admixture of yeast, fire, &c. bread is *generated*; and this bread, broken with the teeth, digested in the stomach, and conveyed through the canals of the body, becomes flesh.

Now, to all this series of *generation*, the only thing effected is a local motion of the parts of the matter, and their setting again in a different order; so that, in reality, wherever there is a new arrangement or composition of elements, there is a new *generation*; and therefore *generation* is finely reducible to motion.

GENERATION is more immediately understood of the production of animal and vegetable bodies from seed, or the coition of others of different sexes, but of the same genus, or kind.

Some modern naturalists maintain, after Mons. Perrault, that there is not properly any new *generation*; that God created all things at first; and that what we call *generation*, are only augmentations and expansions of the minute parts of the bodies of seeds; so that the whole species, to be afterwards produced, were really all formed in the first and included therein; to be brought forth and disclosed to view in a certain time, and according to a certain order and oeconomy.

The manner wherein the seed of the male animal acts on that of the female, in order to impregnate, and render it prolific, has long been enquired after, and remains still a mystery.

The ancients distinguished two kinds of *generation*, *virginale*, called *metaxu*; and *animale*, called also *equivocal*, or *spontaneous*.

The first is that effected by parent animals of the same kind; as that of men, birds, beasts, &c. The second was supposed to be effected by corruption, the sun, &c. as that of insects, frogs, &c. But this latter kind is now generally and deservedly exploded. See EQUIVOCAL.

There are two principal theories, or methods of accounting for the *generation* of animals: the one supposes the embryo, or foetus, to be originally in the seed of the male; the other, in the ovum, or egg of the female.

The *first* supposes the animalcules found in the male seed, to be the first rudiments of the foetus; and that the female only furnishes a proper nidus, and nutriment, to bring them forwards.

The *second* supposes the first rudiments of the animal to be in the ova; and that the male seed only serves to warm, cherish, and ripen the ova, till they fall off out of the ovary into the womb.

Dr. Harvey was of opinion, that all females are furnished with eggs; and that *generation* is effected wholly by means of the male's impregnating the foetus by a kind of contagion communicated to it by the seminal fluid of the male, much in the same manner as the load-stone communicates magnetism to iron. This contagium, he supposes, acts not only on the uterus, but is communicated to the whole body of the female, which is altogether prolific; though the uterus, he acknowledges, is the only part that is capable of conceiving the foetus, just as the brain is alone capable of forming ideas and notions. This ingenious physician and naturalist maintains, that the prolific fluid of the male neither does nor can enter into the womb of the female: but Verheyen has since actually found a great quantity of the male seed in the matrix of a cow, dissected fifteen hours after copulation: and the celebrated Ruysch, having dissected a woman who was surprised in adultery and assassinated on the spot, found a great quantity of the seminal liquor of the male, not only in the cavity of the womb, but also in the *tuba uterina*. Other mistakes into which Dr. Harvey has fallen through the imperfection of the microscope in his time, notwithstanding his accuracy and diligence in observing, have been since detected by Malpighi, Leewenhoeck, and others. The *first* system is well illustrated by Dr. Geo. Garden. That author, upon comparing the observations and discoveries of Harvey, Malpighi, De Graaf, and Leewenhoeck, together, concludes it most probable, "That "all animals are ex animalculo: that these animalcules "are originally in semine masculi, and not in that of the "female: but that they can never come forward, nor "be formed into animals, without the ova in the fe- "male."

The 1st of these points he argues from the three following observations.

1. That something has often been observed by Malpighi, in the cicatricula of an egg before the incubation, like the rudiments of an animal, in form of a tadpole.

2. From the sudden appearance and displaying of all the parts, after incubation, it seems probable, that they are not then actually formed out of a fluid; but that the rudiments of them have been formerly there existent, and are now expanded. The first part of the chick, which is discovered with the naked eye, is the punctum saliens, and that not till three days and nights of incubation are past; on the fifth day the rudiments of the head and body appear. This made Dr. Harvey conclude, that the blood had a being before any other part of the body, and that from it all the organs of the foetus were both formed and nourished; but by Malpighi's observations it appears, that the parts are then only so far extended, as to be made visible to the naked eye; and that they were actually existent before, and discernible by glasses. After a farther incubation of thirty hours, we see the head, the eyes, and the carina, with the vertebræ, distinct, and also the heart. After forty hours, its pulse is visible, and all the other parts more distinct, which cannot be discerned by the naked eye before the beginning of the fifth day: from whence it seems very probable, that even the so early discovery of those parts of the foetus by the microscope, is not the discerning of parts newly formed, but only parts more dilated and extended by receiving of nutriment from the colliquamentum: so that they seem all to have been actually existent before the incubation of the hen. And what Swammerdam has discovered in the transmutation of insects, gives no small light to this; since he makes it appear, that in those large eruca which feed upon cabbage, if they be taken about the time they retire to be transformed into aurelias, and plunged often in warm water, to make a rupture of the outer skin; you will discern, through the transparency of their second membrane, all the parts of the butterfly, the trunk, wings, feelers, &c. folded up: but that, after the eruca is changed into an aurelia, none of those parts can be discerned; but is much drenched with moisture, though they be there actually formed.

3. From the analogy between plants and animals. All vegetables, we see, do proceed ex plantula; the seeds of vegetables being no other but little plants of the same kind, folded up in coats and membranes: whence we may infer, that so curiously an organized creature as an animal, is not the sudden product of a fluid, or colliquamentum, but does much rather proceed from an animalcule of the same kind, and has all its little members folded up according to their several joints and plicatures, which are afterwards enlarged and distended, as we see in plants.

The second point, which our late discoveries have made probable, is, that these animalcules are originally in the seed of the male and not in the female. For,

1. There are observed innumerable animalcula in semine masculino, of all animals. Hartsoeker and Leewenhoek have made this so evident, that there seems little room to doubt of it. See ANIMALCULES.

2. We observe the rudiments of a foetus in eggs which have been fecundated by the male; though no such thing is visible in those not yet fecundated. Malpighi, in his observations, makes it very probable, that these rudiments proceed originally from the male, and not from the female.

3. The resemblance between the rudiments of the foetus in ova, both before and after incubation, with the animalcule, makes it very probable that they are one and the same. The same shape and figure, which Mr. Leewenhoeck gives us of the animalcule, Malpighi gives of the rudiments of the foetus, both before and after incubation; yea, and even the foetuses of viviparous animals appear so at first to the naked eye; whence Dr. Harvey acknowledges, that all animals, even the most perfect, are formed of a worm.

4. This gives a rational account of many foetuses at one birth; and how, at least, a whole cluster of eggs in a hen are fecundated by one coition of the male.

5. This gives a new light, as it were, to the first prophecy concerning the Messia, that, "the seed of the wo- "man shall bruise the head of the serpent," all the rest of mankind being thus most properly and truly the seed of the man.

6. The analogy already mentioned, which we may rationally suppose between the manner of the propagation of plants and animals, does likewise make this probable. Every herb and tree bears its seed after its proper kind; which seed is nothing else but a little plant of that kind; which being thrown into the earth, as into its uterus, spreads forth its roots, and receives thence its nourishment, but has its form within itself; and we may rationally conjecture some such analogy in the propagation of animals.

The

The third thing which our discoveries make probable is that animals cannot be formed of these animalcula without the ova in females, which are necessary for supplying them with proper nutriment; and this is evinced from the following considerations.

1. It appears that an animalcule cannot come forward, if it does not fall into a proper nidus: this we see in the cicatricula in eggs; and though a million of them should fall into one egg, none of them would come forward, but what were in the centre of the cicatricula; and perhaps the situs, necessary for their formation, is so proportioned to their bulk, that it can hardly contain more than one animalcule; which may be the reason why there are so few monsters. This, we see, is absolutely necessary in the oviparous kinds; and the only difference that lies between them and the viviparous, seems to be this, that in the latter the ova are properly nothing but the cicatricula, with its cotiledonum, as that we find in eggs, small specks first appear in the ovaria of viviparous animals may be properly termed an ovum, in relation to the foetus: as it contains not only the cicatricula, with its amnios and cotiledonum, which is the immediate nourishment of the foetus; but also the materials which are to be converted into that cotiledonum; so that the foetus spreads forth its arms no further than in the white and yolk of the egg, from whence it derives all its nourishment. Now, that an animalcule cannot come forward without some such proper nidus, will not be denied; for if there were nothing needful but their being thrown into the uterus, we do not see why many hundreds of them should not come forward at once, at least while fastened to so large a field.

2. That this cicatricula is not originally in utero, seems evident from the frequent conceptions which have been found extra uterum: such as the child which continued twenty-six years in the woman of Thoulouse's belly; and the little foetus found in the abdomen of Mad. de St. Bice, together with the reflexe sero and full of clotted blood; such also seems to be the foetus in the abdomen of the woman of Copenhagen, mentioned in the Nouvi. de la Rep. des Lett. for Sept. 1685; all the members of which were easily to be felt through the skin of the belly, and which she had carried in her belly for four years; the seven years gravidation related by Dr. Cole; and many other the like instances. Now, granting once the necessity of a proper nidus for the formation of an animalcule into an animal, these observations make it probable, that the testes are the ovaria appropriated for this use; for though the animalcules coming thither in such cases, may seem to be extraordinary, and that usually the impregnation is in utero; yet it may be collected from hence, that the cicatricula or ova to be impregnated are in the tubiferi feminei; for if they were not so, the accidental coming of animalcules thither could not make them come forward more than in any other part of the body; since they cannot be formed and nourished without a proper nidus.

3. It is acknowledged, that the foetus in utero, for some considerable time after conception, has no connection with the womb; that it sits wholly loose in it, and is no other than a little round egg, with the foetus in the midst; which sends forth its umbilical cestiles by degrees, and at last lays hold of the uterus. Now from hence it seems evident, that the cicatricula, which is the fountain of the animalcule's nourishment, does not sprout from the uterus, but has its origin elsewhere; and falls in thither as into a fit soil, from whence it may draw nutriment for the growth of the foetus: cele it cannot be easily imagined how it should not have an immediate connection with the uterus, from the time of conception.

It is indeed difficult to conceive, how these eggs should be impregnated per semen maris, both because there is no connexion between the Fallopian tubes, and the ovary for its transmission; and because Dr. Harvey could never discover any thing of it in utero: but as to the last, Mr. Leewenhoeck has cleared that difficulty by the discovery of innumerable animals in the tubes, or cornua uteri, and those living a considerable time after coition. And as to the former, we may rather suppose, that there is such an inflation of the tubes, at the time of coition, as makes them embrace the ovaries; and such an approach of the uterus and its tubes, as that worms easily penetrate the first into the ovary: for all that the ova are impregnated by the animalcules after they are forced into the uterus, and not in the ovary. The former seems probable for this reason, that at least a whole cluster of eggs in a hen will be fecundated by one cock of the flock; now this fecundation seems to be in the ovullary, and not in the uterus, as the eggs pass slowly found to lay: for it can hardly be supposed, that the animalcules should subsist so long, being fettered loose in the uterus, as to wait there for many days, for the fecundation of the eggs as they pass along. The latter conjecture has this to strengthen it; that the animalcula are found to live a considerable time in the uterus: and that, if they should impregnate the ova in the ovary itself, the foetus would circulate so full, that the ova could not pass through the tubes overt; but would either burst the ovary, or fall down into the abdomen, from the orifices of the tubæ: and from hence probably proceed those extraordinary conceptions in the abdomen, out of the uterus. That much is urged for the system of animalcules. See FOETUS.

The retainers to the system of generation of ova contend, that the rudiments of the foetus are laid in the ovary; and that the female furnishes the whole matter of the body; which they chiefly support from the cuticulation from its rubbing, sleep, cows, &c. where the vagina of the womb is so long, and tubulous, that it is scarce possible the male seed should ever arrive within the body of the uterus, especially in cows, whose vagina is filled with cellulæ, valvulæ sinuosæ, and the inner orifice of the uterus is exactly closed besides, that the thickness of the membranes of the ova should seem impenetrable to so crass a matter as the male seed. Add, that if animalcula be found in the male seeds which, however, will admit of some dispute (that imagine motion and agitation of the genital particles thereof, which gave rise to the opinion, being accountable for, from the common laws of warm fluids); yet are the same observed in vinegar, pepper-water, &c. Add, that it is highly improbable, that these animalcula should contain the rudiments of a future body; that their large numbers would produce too plentiful an offspring; inasmuch that it would be necessary for many parts of them to be in vain, and perish; which is contrary to the economy of nature in other things.

Analogy is likewise urged in favour of this system; that all plants are maintained to arise from eggs, seeds being no other than eggs under another denomination. All oviparous animals do unexceptionably arise from eggs; which the females cast forth; and it is highly probable, that the viviparous only differ from the oviparous, in that the females forward hatch their eggs within their selves. Against this hypothesis it is urged, that what are usually called ova, or eggs, in women, are no other than little cells, or bladders, full of a certain liquor; and how can a drop of liquor pass for an egg? Add, that these imaginary eggs have no proper membrane belonging to them, nor any covering but that of the cell; which seems so inseparable therefrom, that, when they are discharged, it is hard to conceive how they should take it with them. And besides, how should they make themselves a passage through the common membrane wherewith the ovary is invested, which is of so close a texture that it will scarce admit any separation by a needle; and if it left a considerable ova of their vesicles? Lastly, animals in all respects perfectly like ova, have been found in other parts of the body, where it is apparent they could not serve for any purposes of generation. Mem. de l'Acad. Royal. de Scien. an. 1708, 1709.

To this it is answered, that ova of vesicles have been actually found in difficilions, detached and separated from the ovary, and the ruptures in the membrane of the ovary, through which they had passed, remaining still visible. Mr. Littre even observed some of these separated ova spread with blood-vessels, like those in the yolks of birds eggs. Nay, more; the same author is positive, that he saw an embryo in one of the ova not yet separated; and could discern its head, mouth, nose, trunk, and funiculus umbilicalis, whereby it adhered to the membranes of the ovary. See GENERATION, § 2.

Sir John Flower starts a difficulty, which seems to prove equally against each system, taken singly: it is fetched from monsters. In a male for instance, which is the production of a venereal copula between an ass and a mare, the bulk of the body partakes of the form of the dam, and the feet, tail, and ears, of that of the sire. Hence it is argued, that the rudiments of the greater part of the foetus are laid in the ovum; and that the impregnation either conveys or changes the extremities. If the male supplied the animalcules, the foetus should always be of the same species as the male: if the female supply it, it should be of her kind; whereas monsters are of both.

These latter seldoms of generation, which indeed so much resemble one another, that they may be reduced to one, have been lately formed from the experiments and observations of Mons. de Buffon, Mons. de Maupertuis, and Mr. Needham.

Mons. de Buffon has endeavoured to prove that the ova in women and quadrupeds are chimeras, and that the

spermatic animalcule cannot be the FOETUS. He could never find any ova which had detached themselves from the ovary, and passed through the Fallopian tube into the matrix. But he discovered a glandular body on the female testicle, which anatomists had mistaken for one of those; which glandular body, at certain times, swelled, opened and discharged a liquor full of the same animalcules, which Leewenhoeck took for living creatures in the semen of males. And Monf. de Buffon adds, that he found bodies perfectly similar to these, not only in the semina of very different animals, but in the infusions of plants, of grains, and in the juices of fish-meats, dreffed and prepared by the fire fo as to leave no creature living in them. From whence this ingenious gentleman concludes, that these pretended animalcules are not future animals of the species of the father: he does not even allow them to be true animals, but fays they are fomething of an intermediate nature between brute matter and animals; parts organized and animated, the aflemblage of which forms the foetus. See Lettres de Monf. de Maupertuis, let. 17.

But the chief difficulty conflits in conceiving how the foetus is formed from these elements. Monf. de Buffon thinks that every part, both of animals and vegetables, contains an infinite number of organic molecules; but that they are much more numerous in the feminal liquors of both fexes, and in the feeds of plants, than in other parts. These organic parts ferve for the nutrition and growth of animals and plants; and the furplus of these parts, when the other purposes to which they are adapted are answered, being reunited in proper interior moulds, corresponding to the fize and fhape of the animal or vegetable to be produced, forms fuch animals or vegetables. And thus the unity and diverfity of the feveral fpecies are preferved and continued. When the quantity of this organic matter is fmall, as in man and moft large animals, *generation* only takes place at a certain age, of maturity, and even then the number of animals is but fmall. In other animals, as in fifhes and moft birds, abounding with thefe organic parts, the cafe is juft the reverfe. With regard to the *generation* of mankind, he fuppofes, that the fuperfluous organic parts are collected together into the feminal veffels of the male and the teflicles of the female, which are the refervoirs deftined to receive them; and in thefe refervoirs, they form a prolific liquor in each fex, which has been previoufly extracted from every part of the body. Thefe feminal liquors, compofed of parts alike active and perfectly analogous to one another, in form and motion, are mixed in the womb, and contribute, by uniting with each other, to the formation of the foetus, which is either male or female, as the feed of the man or woman abounds moft with organic molecules; and the infant refembles either the father or mother, according to the different combinations of thefe molecules. The organic parts of thefe liquors, being equally active, fix and counterbalance each other; fo that the molecules of each parent are determined to form fimilar parts to thofe of the individual that furnifhed them, as the head, arms, &c. The molecules proceeding from the genital parts fix themfelves firft; and the other molecules arrange themfelves fucceffively round thefe in the fame order which they before occupied in the parent. When a great quantity of the feminal liquors of both fexes is received into the womb, there are formed different fpheres of attraction, in different parts of thefe liquors; the confequence of which is that feveral foetufes are formed at the fame time. For a fuller account of Monf. de Buffon's fyftem, we muft refer to his Hiftoire Naturelle, printed at Paris, 1752, where the fubject of the *generation* of animals takes up the greateft part of the third volume.

Monf. de Maupertuis's fyftem, in his Venus Phyfique, has a near refemblance to that of Monf. de Buffon, and tends equally to overturn the fyftems of the ova, and of the fpermatic animalcules, which have prevailed among modern phyfiologifts. He afcribes the formation of the foetus to the mixture of the male and female feed, by means of the affinity and mutual attraction of the corresponding parts that compofe them. And to confirm his own and Monf. de Buffon's opinion, he adds an account of a fingigitary family, as he calls it, at Berlin, many of which had a fupernumerary finger or toe, and fometimes both. He fays that this fexigitism, or multiplicity of having fupernumerary fingers or toes, has been tranfmitted equally by the father and by the mother; that it was loft by alliances with thofe who had but the common number of fingers. He adds, that he does not believe that any one will afcribe the continuation of fexdigitism in a family, to chance; thefe fupernumerary parts might have been accidental varieties at firft, but if they be once eftablifhed by a fufficient number of *generations*, where both fexes have had them, they then become a foundation for a diftinct fpecies; and perhaps all the different fpecies, difcernible in animals of the fame kind, have been multiplied in this way. What we may obferve in other animals gives ground for thefe fufpicions. See the letter before cited.

Mr. Turberville Needham, in his Summary of Obfervations on the *Generation*, Compofition, and Decompofition of Animal and Vegetable Subftances, having offered feveral objections againft the fyftems of *generation* by eggs and by animalcules, recites a multitude of experiments, from which he concludes, that there are no pre-exiftent germs formed for the production of animals and vegetables; but that matter, in fome degree organized in its minute aflemblages, gives birth to them, and that the gradation between animal and vegetable life is much more familiar and eafy than it had before appeared to be. He fuppofes, in conformity to the doctrine of Monf. de Buffon, that there are in matter certain organical parts, difpofed for the formation of animal and vegetable fubftances: that thefe by coalition, conftitute the *prima flamina* of all animal and vegetable bodies, which are fimple, uniform, and common to all, and confequently to be found in a certain quantity in every portion of food, aliment, or nutritive juice; and from thence to be digefted, and when the fubject becomes adult, to be fecreted and ftrained, for the formation of the feed of every plant and animal; and in this fluid or fubftance to be afterwards found in great abundance. Their organic parts are declared to be moving when difengaged, living in appearance, and endued with certain organs, but extremely fimple in their compofition; being perhaps little more than elaftic fprings more or lefs compreffed, and more or lefs diverfified in the direction of their force. Into thefe organical principles Mr. Needham refolves that clafs of beings which has been denominated microfcopic animals. He tells us, that feeds macerated in water firft difunite into fmall particles, motionlefs and feemingly inert; but that thefe particles by degrees afterwards arrive at a power of motion, and feem alive, though in reality they are not fo. The author deduces the fame obfervations from experiments on the juices of animals, mutton gravy, and the like; and affirms, from the whole, that no axiom was ever more true than that of the ancients, *corruptio unius eft generatio alterius*, though they draw it from falfe principles, and fo eftablifhed it as to render *generation* equivocal. He then proceeds to the examination of the male femen of animals; and affirms, that thefe animalcules appearing like tadpoles, which others have obferved in this femen, are produced fubfequently to the evacuation of this fluid, and have their origin from principles contained in this matter, either by evolution of organical parts, as Buffon fuppofes, or, as Mr. Needham thinks, from a real vegetation, and a change from the vegetable to the animal life. He fays, that the femen, immediately evacuated, and viewed by the microfcope, appears an homogeneous fluid; that, after a few moments, it begins to liquefy; then to fhoot out into long filaments and ramifications on every fide; which afterwards open and divide into moving globules, trailing after them fomething like long tails; thefe tails are in reality no parts of the animals, but long ftrings or filaments of the vifcid feminal fubftance, which gradually become fhorter and fhorter, till at laft the globules get rid of them, and fwim equally in the fluid. This vegetative power, in parts of the femen, of fhooting into filaments, Mr. Needham found to refide in all fubftances animal and vegetable, and in every part of thofe fubftances, as far as the fmalleft microfcopical point; and to this he attributes all that is called animal life in the fluids, produced from vegetables, or the infufions of them: and from hence he concludes with M. Buffon, that there is a real productive force in nature. He adds, that there is a vegetative force in every microfcopical point of matter, and in every vifible filament of which the whole animal or vegetable texture conflits; and he alfo conjectures, that this force extends much farther; becaufe in all his obfervations, the whole fubftance, after a certain feparation of falts and volatile parts, divided into filaments and vegetated into numberlefs zoophytes, which yielded all the feveral fpecies of common microfcopic animals; and thefe animals alfo, after a certain time, fubfided to the bottom, became motionlefs, refolved again into a gelatinous filamentous fubftance, and gave zoophytes and animals of a leffer fpecies. The cafe is the fame, he fays, with regard to the fpermatic animalcules as well as the others, and, therefore, he reduces them all to the fame clafs of beings. From thefe facts he infers, that every animal or vegetable fubftance advances as faft as it can in its refolution to return to one common principle, the fource of all, or a kind of univerfal femen, from which its atoms may return again and afcend to a new life. He obferves farther, that the

several species are kept distinct, because the specific seed of one animal must undergo many changes, and acquire singular properties peculiar to itself, since it proceeded from the homogeneous element, in which all kinds coincide. The active vegetating force that resides in it must be precise; its quantity must be exactly proportioned to the nature, solidity, tenacity, quantity, and resistance of the ductile matter through which it passes; and these combinations are very different in different subjects: besides, times and circumstances produce a change in it, which is a source of variety, even during the time of gestation. Thus, the specific semen of one animal can never be moulded into another, and seeds may differ specifically from one another by many invisible principles totally unknown to us, and unattainable by experiments; so that these is no danger of falling into equivocal *generation*: however, these principles, though capable of diffusing combinations, admit only of a limited variation, and never deviate farther than is consistent with univocal *generation*. Mr. Needham also observes, that the animalcules in the semen of animals, and in the infusions and juices of animal and vegetable substances, are not of the nature of any other beings, or to be ranked with them; that they constitute a class apart from all others, the characteristic of which is, that they are neither generated nor subsist by nutriment, as other plants and animals do, nor generate in the ordinary way. Of this class, he apprehends, is that species of polype, called the bell animal; owing its formation to the decomposition of some water plant, but approaching towards the nature of other animals, as, when once generated, it eats, and even generates as other animals do. He closes his system with observing, that the lower this new class of beings is pitched, the less was its vegetating force impeded by resisting matter; that the degree of exaltation in the matter from which they were formed was always the higher, and their motion the swifter; and he hence conjectures, that an animal substance may be exalted this way into a poison, or a contagious vapour; and that in this way stagnating waters become poisonous, and that even the poison of the viper, and other such animals may be owing to the same principles: nay, that this vegetable active force, when confined, may be the spring of all the mechanical forces of the body, and of the impressions which affect the soul.

Mr. Needham's system may be summed up in a few words: he supposes all semen of any kind to be an exalted portion of animal or vegetable matter, secreted from the aliment of every generating subject, when it is adult, and no farther demand is made for its increase or growth; this is endued with a proportionable vegetating force; and it varies in various circumstances, and heterogeneous in different subjects, but uniform in its productions, when it falls into a proper matrix, where it finds matter to assimilate of a proper quality, and in a quantity sufficient to form that specific being; whilst in other circumstances, it will, if it extravasates, by the same vegetating force, produce the several phenomena which he has ascribed to it. Phil. Trans. vol. xlv. p. 615, &c.

GENERATION *of man*. As it is in human subjects that the gradual process of *generation* has been principally inquired into, and the structure and office of the organs subservient thereto, chiefly examined; what the latest naturalists and anatomists have settled with regard to it, is referred for this head.

The parts of *generation*, then, are different in the different sexes. Those proper to the male, are the penis, the testicles, the vesiculæ seminales, the vasa deferentia, the præstatæ and the vasa præparantia; which see described each under its proper article, PENIS, TESTICLE, &c. The parts of *generation* proper to the female are the PUDENDUM, the CLITORIS, NYMPHÆ, HYMEN, UTERUS, FALLOPIAN TUBES, and OVARIES or TESTES.

The process of *generation*, so far as the male contributes to it, is as follows. The penis being erected by an affusion of blood; as shewn under ERECTION; the glans at the same time tumefied; and the nervous papillæ in the glans much rubbed, and highly excited, in coitu; an ejaculatory contraction follows, by which the seed is pressed out of the seminal vesicles, and expelled with some considerable force.

The process of *generation* on the one part of the female is thus: the clitoris being erected, after the like manner as the penis in man; and the neighbouring parts all distended with blood; they more subsequately embrace the penis in coitu: and, by the titillescence, press out a liquor from the glands about the neck of the womb, to facilitate the passage of the penis.

At the same time, the fibres of the womb, contracting, open its mouth (which at other times is extremely close) for the reception of the finer part of the seed.

Thus the seed pregnant with animalcules, is conveyed with some impetus, into the uterus: where being received by the convulsive restriction of the inner membrane thereof, and farther heated and agitated therein, it is prepared to impregnate the ovum.

During the act of coition, the Fallopian tubes erect themselves, embrace the ovaries with their strong muscular edges, like fingers, and compress them, till their mouths being dilated and expanded by the embrace, force the egg now ripened, into their cavities, and gradually drive it forwards, by their vermicular motion, till at last they protrude it into the cavity of the womb to meet the seed, some of the animalcules whereof, entering the dilated pores of the glandulous membrane of the egg, are there retained, nourished, grow to its navel, and suffocate the rest of the less lively animalculæ. And thus is conception performed.

Others rather suppose the seed conveyed from the uterus, through the Fallopian tubes, to the ova; and thus take the impregnation to be first performed in the ovaries; or even in the tubæ themselves, the ova and seed meeting by the way.

Others, considering the closeness of the mouth of the womb, and the thickness of the membranes of the ovaries, judge it impossible for the seed to pass that way; and therefore suppose it is taken up by the veins which open into the cavity of the vagina, or even the womb; where circulating, it fermenes with the mass of blood; and hence all the symptoms which appear in conception.

At length it enters and impregnates the egg by the small twigs of arteries which are upon its membranes. This fermentation swelling the membranes of the tubæ, they open the cavity, and make room for the ova to pass into the womb.

The egg impregnated, and close shut up in the womb, swims in the humours thereof; which, growing more and more subtil, enter the parent pores found on one side the ovum, and soon distend, fill and augment it; and there being still farther attenuated, nourish the embryo; thicken and expand the membranes of the ovum, especially in that part by which it grew to the ovary; and thus form the rudiments of a placenta.

The same causes still continuing, and the pores both of the placenta and the membranes being enlarged; the egg begins to fill the capacity of the womb; and at length its stem or calyx grows to the concave surface thereof; and thus is the navel-string, or funiculus formed. See FOETUS and *Funiculus* UMBILICALIS.

This system is founded on the supposition of animalcula in the male seed. They who set them aside as unconcerned in *generation*, account for it thus: the seed, containing volatile, oily, and saline parts, as appears from its fetid smell, oleaginous substance, &c. being lodged in the womb, and there farther digested and exalted, grows yet more volatile, fetid, pungent and stimulating; and thus, adding to the heat occasioned by coition, vellicates the nervous fibres of that part, and occasions a fermentation, and gentle inflammation; and by that means an extraordinary flux of humours to that, and the adjacent parts.

By this means the tubæ become rigid, and fit to grasp the ovaries, which are also heated by the effluvia of the semen and the warmth of the parts surrounding. Upon this there is a greater flux into the ovaries; till at length, the ova, some of them at least, by such greater supply of nourishment, increase in bulk; and as those grasped by the edges of the tubæ will be kept warmest, and the greatest flux be made thereto, they will soonest be ripened, fall off, and be received by the tubæ, and conveyed to the womb; where growing, after the manner of the seeds of plants, the placenta at length takes hold of, and adheres to, the uterus; from which time the embryo begins to be nourished after a different manner. See GESTATION, NUTRITION and CIRCULATION.

GENERATION *of fishes, fossils, insects, metals, minerals, mushrooms*. See FISH, FOSSILS, INSECTS, &c.

GENERATION *of plants*. See *Generation* of PLANTS. See also FARINA, FLOWER, FRUCTIFICATION, PISTIL, and STAMINA.

GENERATION *of shells*. See SHELLS.

GENERATION *of stones*. See STONES, SPAR, TROCHITES, and CRYSTALS.

GENERATION, in *Mathematics*, is used for formation or production. Thus we meet with the *generation* of equations, curves, solids, &c.

GENERATION, in *Theology*. The father is said by some divines, to have produced his Word, or Son, from all eternity, by way of *generation*; on which occasion the word *generation* raises a peculiar idea: that procession, which is really effected in the way of understanding, is called *generation*, because in virtue thereof, the Word becomes like to him from whom he takes this original; or, as St. Paul expresses

expreſſes it, is the figure or image of his ſubſtance, i. e. of his being and nature. See TRINITY and PERSON. And hence it is, they ſay, that the ſecond Perſon in the Trinity is called the Son.

GENERATION is alſo uſed, though ſomewhat improperly, for GENEALOGY, or the ſeries of children iſſued from the ſame ſtock. Thus, the goſpel of St. Matthew commences with *the book of the generation of Jeſus Chriſt*, &c. The latter, and more accurate tranſlators, inſtead of *generation* uſe the word *genealogy*.

GENERATION is alſo uſed to ſignify a people, race, or nation, eſpecially in the literal tranſlation of the ſcripture, where the word generally occurs wherever the Latin has *generatio*, and the Greek γενεα, γενεαι.

Thus, "A wicked and perverſe *generation* ſeeketh a ſign," &c. "One *generation* paſſes away, and another cometh," &c.

GENERATION is alſo uſed in the ſenſe of an age, or the ordinary period of man's life.

Thus we ſay, in the third and fourth *generation*. In this ſenſe, hiſtorians uſually reckon a *generation* the ſpace of thirty-three years, or thereabouts. See AGE.

Herodotus makes three *generations* in an hundred years; which computation appears, from the later authors of political arithmetic, to be pretty juſt. See CHRONOLOGY and POLITICAL *arithmetic*.

GENERICAL *name*, in *Natural Hiſtory*, the word uſed to ſignify all the ſpecies of natural bodies, which agree in certain eſſential and peculiar characters, and therefore all of the ſame family or kind; ſo that the word uſed as the *generical* name equally expreſſes every one of them, and ſome other words expreſſive of the peculiar qualities or figures of each are added, in order to denote them ſingly, and make up what is called the ſpecific name.

Thus the word ROSA, or roſe, is the *generical* name of the whole ſeries of flowers of that kind, which are diſtinguiſhed by the ſpecific names of the red roſe, the white roſe, the apple roſe, &c. The ignorance of former ages, in the true principles of natural hiſtory, has occaſioned the bodies, which are the objects of it, to be arranged into very unnatural ſeries under the name of *genera*; and theſe have been called by names as improper as the characters they were diſtinguiſhed by. Linnæus has done a great deal in expoſing the bad *generical* names in BOTANY; and Artedi has applied his rules about the formation of theſe names with very little difference to the ſubjects of ICHTHYOLOGY.

Many of the *generical* names of fiſh, till the time of this author, were ſo barbarous and obſcure, that it was not eaſy to trace them to their original, or to find whether they were truly Teutonic, Engliſh, Dutch, Sweediſh, French, Italian, Spaniſh, Portugueſe, Latin, or Indian. The ignorance of the writers on theſe ſubjects, or their too ſcrupulous adherence to the cuſtoms of their predeceſſors, ſeem to have been principally the cauſes of this, and often an entire negligence. Artedi's rules for *generical* names for fiſh are theſe: whatever fiſh there are which agree in the ſame *generical* characters, and are properly of the ſame genus, theſe ought all to be called by the ſame *generical* name, their differences being only expreſſed by ſpecific ones. This appears ſo plain, to juſt, and ſo neceſſary a rule, that it is almoſt a ſhame to ſay it down; yet the writers on fiſh, till the time of this author, had very ſeldom obſerved it.

Another barbariſm and impropriety in the *generical* names of fiſh among the old authors, is the uſing of the ſame words to expreſs them, which are alſo the names of other animals, quadrupeds, birds, and reptiles. Theſe are ſubject to great objection; becauſe when they are uſed, it is not eaſy to ſee, in ſome caſes, whether the author is ſpeaking of a bird, a beaſt, or a fiſh. It is therefore one of the general rules of Artedi, that all theſe names are to be aboliſhed, as alſo all thoſe which are common to fiſh, and to plants, minerals, and to the tools of huſbandry, or other ſervices.

Another rule of this excellent author is, that *generical* names that are compoſed of two whole words, unnaturally tied together, are to be aboliſhed, it being eaſy to contrive names leſs barbarous, and as expreſſive: next to theſe are to be exploded thoſe names which are formed of two *generical* words before in uſe, the one broken or cut ſhort, the other preſerved entire.

Another general rule in regard to theſe names is, that all ſuch as are not of either Latin or Greek origin, are to be proſcribed and wholly rejected. This rule cuts off a prodigious number of barbarous words, with which we find the books of authors of former ages on theſe ſubjects crowded.

A ſixth rule for the regulating *generical* names is, that all ſuch are to be aboliſhed as terminate in *odes*, as expreſſing a reſemblance often imaginary, and often alluding to ſomething unknown, or rendered difficult to trace from the changes which the names of other things have undergone ſince the time when it was formed. Theſe words convey no idea of the character of the genus expreſſed by them, except that they are like the other thing alluded to in ſome external, though perhaps not eſſential character: of this kind are the rhomboides, ſcorpioides, &c.

A ſeventh rule in regard to theſe names is, that all ſuch are to be rejected as are barely diminutives, and terminate in *ides* or *ulus*. Theſe convey no other idea, but that of the fiſh being like ſome other fiſh, only leſs: now bigneſs is no *generical* character; therefore if this genus, and that referred to, differ only in ſize, they have no *generical* difference at all; if they do differ otherwiſe, they ſhould be expreſſed. What makes many of theſe names alſo more intolerable is, that they allude not to fiſh, but to other things ſo different in their nature, that there muſt needs be many other more eſſential varieties between them, beſide ſize.

Another general rule is, that ſuch *generical* names as are pure Latin, but are mere adjectives, are to be exploded, there being no reaſon for uſing them as ſubſtantives.

A ninth general rule is, that ſuch names as are formed of Latin words, unknown to the ancient Romans, and formed by the later writers, are to be expelled as barbarous, and others of better credit placed in their ſtead.

Finally, ſuch *generical* names as have been given to fiſh from the places where they are caught are to be rejected; of this kind are the ſardelle and ſardina from the iſland of Sardinia, and the ſturio from Aſturia, a province of Spain. Theſe ſorts of names can convey no idea of the nature of the fiſh, and may belong as well to one genus as to another. Artedi, Ichthyolog. p. 10. 69. 73. 79.

Theſe rules of proſcription baniſh ſo many of the received *generical* names of fiſh, that it might be ſuppoſed the whole number was exhauſted, and all the fiſh in the world to be named anew. But this is not the caſe; the *genera* are in reality much fewer in number than they have been uſually ſuppoſed, and therefore fewer words will ſerve to expreſs them, and there yet remain many truly Latin words uſed by the ancient Romans, by which the far greater part of the *genera* may be expreſſed, and the few remaining may be beſt denominated by compound Greek words, expreſſive of their real characters.

Among the true and genuine Latin, and Græco-Latin names of the *genera* of fiſh, are theſe: accipenſer, amia, anthias, balana, blennus, clupea, cobites, cyprinus, delphinus, elops, eſox, exocœtus, gobius, labrus, lamia, liparis, mugil, mullus, muræna, perca, phyſeter, priſtis, raja, ſalmo, ſalpa, ſcarus, ſcomber, ſilurus, ſparus, ſqualus, thynnus, torpedo, triton, turdus, uranoſcopus, xiphias, zeus. Theſe will go a great way toward the naming the true *genera*. Artedi has merited greatly of the world, in thus reforming the names of fiſh; and the rules he has laid down, thus given at large, may, with little variation, be made to ſerve for any other author, in whatever branch of knowledge he has occaſion to write.

GENERIS *ſecundi*. See SECUNDI.

GENEROSA, *a gentlewoman*. See GENTLEWOMAN and SPINSTER.

GENESIS, the firſt book of the Old Teſtament, containing the hiſtory of the creation, and the lives of the firſt patriarchs.

The book of *Geneſis* ſtands at the head of the Pentateuch. Its author is held to be Moſes: it contains the relation of 2369 years, viz. from the beginning of the world to the death of Joſeph. The Jews are forbid to read the beginning of Geneſis, and the beginning of Ezekiel, before thirty years of age.

The Hebrews called this book *Bereſchith*, becauſe it begins with that word, which in their language ſignifies *in principio, or in the beginning*. The Greeks gave it the name *Geneſis*, Γενεσις, q. d. production, generation, becauſe it begins with the hiſtory of the production or generation of all beings.

This book, beſides the hiſtory of the creation, contains an account of the original innocence and fall of man; the propagation of mankind; the riſe of religion; the general defection and corruption of the world; the deluge; the reſtoration of the world; the diviſion and peopling of the earth; and the hiſtory of the firſt patriarchs to the death of Joſeph. It was eaſy for Moſes to be ſatisfied of the truth of what he delivers in this book, becauſe it came down to him through a few hands: for, from Adam to Noah, there was one man, viz. Methuſelah, who lived ſo long as to ſee them both: in like manner Shem converſed with Noah and Abraham; Iſaac with Abraham and Joſeph, from whom the records of this book might eaſily be conveyed to Moſes by Amram, who was contemporary with Joſeph. Patrick.

GENESIS, in *Geometry*, denotes the formation of a line, plane, or ſolid, by the motion or flux of a POINT, LINE, or SURFACE. See FLUXION and CURVE.

The

The *genesis*, or formation, e. gr. of a globe or sphere, is conceived by supposing a semicircle to revolve upon a right line, drawn from one extreme thereof to the other, called its axis, or axis of circumvolution: the motion or revolution of that semicircle is the *genesis* of the SPHERE, &c. See GLOBE.

In the *genesis* of figures, &c. the line or surface that moves is called the *describent*; and the line round which, or according to which, the revolution or motion is made, the *directrix*.

GENET, or *Jennet*, said to be derived from *regnet, bene natus*, in the *Moorish*, &c. a small-sized, well proportioned Spanish horse.

Some also give the term *genets* to well-made Italian horses.

To ride a la GENETTA, is to ride in the Spanish fashion, i. e. with the stirrups so short, that the spurs bear upon the flanks of the horse. This is deemed a piece of gallantry in Spain, but not among us.

GENETHLIA, Γενθλια, in *Antiquity*, a solemnity kept in memory of some person deceased.

GENETHLIACI, in *Astrology*, persons who erect horoscopes, or pretend to foretel what shall befall a man, by means of the stars which presided at his nativity.

The word is formed of the Greek γενθλιον, *origin, generation, nativity*.

The ancients called them *Chaldæi*, and by the general name *mathematici*: accordingly, the several civil and canon laws, which we find made against the mathematicians, only respect the *genethliaci*, or astrologers.

They were expelled Rome, by a formal decree of the senate; and yet found so much protection from the credulity of the people, that they remained therein unmolested. Hence an ancient author speaks of them as *hominum genus, quod in civitate nostra semper & vetabitur, & retinebitur*.

Antipater and Archinapolus have shewn, that *genethliology* should rather be founded on the time of the conception than on that of the birth. Vitruvius.

GENETHLIACUM, GENETHLIAC *poem*, is a composition in verse, on the birth of some prince, or other illustrious person; wherein the poet promises him great honours, advantages, successes, victories, &c. by a kind of prophecy or prediction. Such is the eclogue of Virgil to Pollio, beginning,

Sicelides Musæ, paulo majora canamus.

There are also *genethliac* speeches or orations, made to celebrate a person's birth-day.

GENETIDES, in *Natural History*, a name given by the ancients to the stone, more generally known under the name enchymonites. This was the spar incrusted on the tops and sides of subterranean caverns, which they supposed daily to bring forth more, and therefore gave the powder of it to women at the time of their lying-in, to promote their speedy delivery.

GENETTA, a small animal of the weasel kind. See GINETTA.

GENETTE, in the *Manege*, a Turkish bit, the crub of which is all of one piece, and made like a large ring, and placed above the liberty of the tongue. When they bridle a horse, they make his chin pass through this curb, which surrounds his beard. This sort of bit was much used at the court of France when Guillet wrote. See GENET.

GENETYLLIS, Γενετυλλις, in *Antiquity*, a solemnity celebrated by women in honour of *Genetyllis*, the goddess of that sex.

GENEVA, or GIN, a popular name for a compound water, which is, or ought to be, procured from the berries of the juniper-tree, distilled with brandy or malt-spirits.

The word is formed from *genevre*, the French name of the juniper-berry.

The best *genevas* we now have, is made from an ordinary spirit, distilled a second time with an addition of some juniper-berries; but the original liquor of this kind was prepared in a very different manner. It was a custom in the distilling of spirits from wort, or other fermented liquors, to add in the working some aromatic ingredient, such as ginger, cortex Winteranus, or grains of paradise, to take off the bad flavour, and to give a pungent taste to the spirit. Among other things used with this intent, some tried the juniper-berries, and finding that they gave not only an agreeable flavour, but very valuable virtues also to the spirit, they brought it to a general custom, and the liquor sold under this name. The method of adding the berries was to the malt in the grinding: a proper proportion was allowed, and the whole was reduced to meal together, and worked in the common way. The spirit thus obtained was flavoured *ab origine* with the berries, and exceeded all that could be made by any other method. Our common distillers leave out the juniper-berries entirely from the liquor they now make and sell under that name. Our chemists have by them into the secret, that the oil of juniper-berries, and that of turpentine, are very much alike in flavour, though not in price; and the common method of making what is called *genevas* in London, is with common malt spirits and a proper quantity of oil of turpentine distilled together. Shaw's Essay on Distill. p. 7. See DISTILLING.

GENEVIEVE, St. GENEVIVE, or St. GENEVIEVE, fathers or religious of St. *Genevieve*, the name of a congregation of regular canons of the order of St Augustine, established in France.

The congregation of St. *Genevieve* is a reform of the Augustine canons. It was begun by St. Charles Faure, in the abbey of St. Vincent de Senlis, whereof he was a member, in the year 1618.

In the year 1634, the abbey was made elective; and a general chapter, composed of the superiors of fifteen houses who had now received the reform, chose F. Faure coadjutor of the abbey of St. *Genevieve*, and general of the whole congregation. Such were its beginnings.

It has since increased very much, and it now consists of above a hundred monasteries; in some whereof the religious are employed in the administration of the parishes and hospitals; and in others, in the celebration of divine service, and the instruction of ecclesiastics in seminaries for the purpose.

The congregation takes its name from the abbey of St. *Genevieve*, which is the chief of the order, and whose abbot is the general thereof. The abbey itself took its name from St. *Genevieve*, the patroness of the city of Paris, who died in the year 512. Five years after her death, Clovis erected the church of St. Genevieve, under the name and invocation of St. Peter, where her relics are still preserved, her shrine visited, and her image carried with great processions and ceremonies, upon extraordinary occasions, as when some great favour is to be intreated of heaven.

GENIAL, GENIALIS, an epithet applied by the ancients to certain deities, whom they supposed to preside over generation.

They were thus called *a gerendo*, from bearing; or, according to the correction of Scaliger and Vossius, *a genendo, to yean, produce*: yet Festus says, that they were also called *geniti*, which seems to require the former reading. M. Dacier, in a note, shews that *genere* has the sense of *nuptiæ*.

Among the *genial* gods, *dii geniales*, says Festus, were water, earth, fire, and air, which the Greeks called *elements*. The twelve signs were sometimes also ranked in the number; as also the sun and moon.

GENICULARIS, in *Botany*, a name used by some authors for the great garden valerian, called *phu*. Ger. Emac. Ind. 2.

GENICULI, in *Botany*, the joints or knots which appear in the shoots of plants; whence botanists call those marked therewith *geniculate plants*.

GENIOGLOSSI, in *Anatomy*, the name of a pair of muscles, proceeding inwards from the fore-part of the lower jaw, under another called *genio-hyoidæi*; and which, enlarging themselves, are fastened into the base of the tongue. They serve to pull the tongue forward, and to thrust it out of the mouth.

The word is formed from γενυς, *maxillus, the chin*; and γλωσσα, *lingua, the tongue*.

GENIO-HYOIDÆUS, in *Anatomy*, a muscle of the *os hyoides*, which, with its partner, is short, thick, and fleshy, arising from the internal parts of the lower jawbone, called the chin; and dilating themselves, are soon lessened again, and inserted into the superior part of the fore-bone of the *os hyoides*. These pull upwards and forwards the *os hyoides*, and assist the *genio-glossi* in thrusting the tongue out of the mouth.

The word is formed from γενυς, *mentum, the chin*; and ειδος, *figura*.

GENIO-PHARYNGÆUS, in *Anatomy*, is a name given by Winslow to a muscular portion, really distinct from the *genio-glossus*, inserted in the side of the pharynx, and joined to the *genio-glossus* all the way to the chin.

GENIPA, in *Botany*, the name of a genus of plants of the *pentandria monogynia* class, the characters of which are these: the flower is of the monopetalous kind, and is shaped like a bell, and very wide at the mouth: the pistil arises from the cup, and is fixed in the manner of a nail to the hinder part of the flower. The cup finally becomes an oval fleshy fruit, divided into two cells, and containing a number of flatted seeds. There is only one known species of this genus, which is the oval-fruited *genipa* or *genipee* of authors.

GENISTA, in *Botany*. See BROOM.

GENISTELLA, in *Botany*, the name of a species of *genista*.

GENITA-*mens*, in *Mythology*, a goddess who presided over child-birth, to whom the Romans sacrificed a dog.

GENITAL, GENITALIS, in *Anatomy*, something that relates to generation.

Genital parts denote the parts in both sexes employed in generation, otherwise called *natura*, *pudenda*, or *pudenda*. *See Tab. Anat. (Splanch.) fig. 8, 9, 10, 11, 13, 15, &c.* See PENIS, TESTACLE, CLITORIS, HYMEN, &c.

GENITAL *gods, dii genitales*, are sometimes used in the ancient Roman poets for those we otherwise call INDIGITES.

Ausonius, in the argument of the fourth book of the *Æneid*, takes the word in a different manner; the *dii genitales*, he observes, were such as were not born of human parents, and were not thus called *quasi geniti ex hominibus*, but rather because they themselves had begot human children.

GENITALIA, or GENITORIES, in *Anatomy*, a name sometimes given to the testes or testicles of a man, on account of their office in generation.

GENITED, in *Gunnery*. See GENERATED.

GENITES, TENITÆ, or GENETEI, among the *Hebrews*, those that descended from Abraham, without any mixture of foreign blood.

The Greeks distinguished by the name of *genites* such of the Jews as were issued from parents, who, during the Babylonish captivity, had not allied with any gentile family.

GENITIVE, in *Grammar*, the second case of the declensions of nouns.

The relation of one thing considered as belonging in some manner to another, has occasioned a peculiar termination of nouns, called the *genitive* case.

In English, the *genitive* case is made by prefixing the particle *of*; in French, *de*, or *du*, &c. though, in strictness, there are no cases at all, or at most only two, in either of those languages, inasmuch as they do not express the different relation of things by different terminations, but only by additional prepositions. See CASE. In the Latin, this relation is expressed in divers manners: thus we say, *caput hominis, the head of a man; color rosæ, the colour of a rose; opus Dei, the work of God*, &c.

As the *genitive* case serves to express very different, and even opposite relations, there sometimes arises an ambiguity therefrom: thus, in the phrase *vulnus Achillis, the wound of Achilles*, the *genitive*, *Achillis*, may either signify passively the wound Achilles has received, or actively the wound Achilles has given: thus, in that passage of St. Paul, *Certus sum quod neque mors neque vita, &c. me poterit separare a charitate Dei in Christo, &c.* the *genitive*, *Dei*, has been taken by interpreters in two different senses; some, giving it the relation of object, understand the passage of the love which the elect bear to God in Jesus Christ; whereas others give it the relation of subject, and explain it of the love which God bears the elect in Jesus Christ.

In the Hebrew tongue, the *genitive* case is marked after a manner very different from that of the Greek and Latin; for whereas in those languages the noun governed is varied, in the Hebrew the noun governing undergoes the alteration.

GENITURA, GENITURE, a name which some authors give to the SEED, both that of the male and female.

GENITURA, in *Botany*, a name given by some authors to the anethum or DILL, a plant common in gardens, and used in medicine and cookery.

GENIUS, in *Mythology*, a good or evil spirit, or demon, whom the ancients supposed set over each person, to direct his birth, accompany him in life, and be his guard, until death. Those that attended women were females, and called *Junones*; but those that attended men were males, and called *Genii*. They seem, in their original, to be nothing else but the particular bent and temper of each person deified; and as every one's own temper is in a great measure the cause of his happiness or misery, each of these were supposed to share, and have an equal feeling, in all the enjoyments and sufferings of the persons they attended. See Horace, lib. ii. epi. 2. ver. 189. The ancients had their *Genii* of nations, of cities, of provinces, &c. Nothing is more common than the following inscription on medals: GENIUS POPULI ROM. *the* Genius *of the Roman people*: or, GENIO POP. ROM. *to the* Genius *of the Roman people*.

In this sense, *genius* and *lar* were the same thing; as, in effect, Censorinus and Apuleius affirm they were.

The Platonists, and other eastern philosophers, supposed the *Genii* to inhabit the vast region, or extent of air, between earth and heaven. They were a sort of intermediate powers, who did the office of mediators between gods and men. They were the interpreters and agents of the gods; communicated the will of the deities to men; and the prayers and vows of men to the gods. As it was unbecoming the majesty of the gods to enter into such trifling concerns, this became the lot of the *Genii*, whose nature was of a middle kind between the two; who derived immortality from the one, and passions from the other; and who had a body framed of an aereal matter. Most of the philosophers, however, held that the *genii* of particular men were born with them, and died. Thus Plutarch attributes the ceasing of oracles partly to the death of the *Genii*.

The heathens, who considered the *Genii* as the guardian spirits of particular persons, believed that they rejoiced and were afflicted at all the good and ill fortune that befell their wards. They never or very rarely appeared to them; and then only in favour of some person of extraordinary virtue or dignity. They likewise held a great difference between the *Genii* of different men; and that some were much more powerful than others; on which principle it was, that a wizard in Appian bids Antony keep at a distance from Octavius, because Antony's *Genius* was inferior to, and stood in awe of, that of Octavius.

There were also evil *Genii*, who took a pleasure in persecuting men, and bringing them evil tidings: such was that in Patterculus, &c. which appeared to Brutus the night before the battle of Philippi. These were also called *larvæ* and *lemures*. See DEMON.

GENIUS is more frequently used for the force or facility of the soul, considered as it thinks or judges.

Thus, we say, a happy *genius*, a superior *genius*, an elevated *genius*, a narrow confined *genius*, &c. In like sense we also say, a work of *genius*, a want of *genius*, &c.

GENIUS is also used, in a more restrained sense, for a natural talent, or disposition to one thing more than another. In which sense we say, a *genius* for verse, for the sciences, &c. For the difference between *genius* and taste, *see* TASTE.

GENOA *balsam*, in *Medicine*, the name of a famous composition, called also the *balsam of Aquapendente*. Its great virtues are the curing pains in the extremities of the body, and allaying the violent pains in the bowels, to which many women are subject after delivery. The precipitation is given at large in Velschius, but the medicine is now out of use.

GENS D'ARMES. See GENDARMES.

GENTIAN, or FELWORT, *Gentiana*, in *Botany*, a genus of the *pentandria digynia* class. Its characters are these: it hath a permanent empalement to the flower, cut into five acute segments; the flower hath one petal, which is tubulous, and cut into five flat parts at the top; it hath five awl-shaped stamina, shorter than the petal, terminated by single summits; in the centre is situated an oblong, cylindrical germen, having an style, but crowned by two oval stigmas, which afterward becomes an oblong taper-pointed capsule with one cell, containing many small seeds fastened to the valves of the capsule. There are twelve species, one of which is the common *gentian* of the shops, whose root is one of the principal ingredients in bitters: it grows naturally in the pastures in Switzerland, and in the mountainous parts of Germany; from whence it is brought to England for medicinal use.

The ancients, to render it the more considerable, denominated it from Gentius, king of Illyria, who is supposed to have been the first that discovered the admirable virtues of this plant.

The root *gentian* is of a yellowish colour, and extremely bitter: it is sometimes as thick as the arm, but more commonly divided into branches no bigger than the thumb: its stem grows several feet high, being very smooth and glossy, though divided by knots from space to space, out of which arise the leaves, which somewhat resemble those of plantain. Its flowers, which likewise accompany the knots, are yellow, and its seed is flat, round, smooth, and light.

The root is to be chosen dry, new, of a moderate thickness, free from earth, and furnished with little branches or fibres; and it possible, that which is dried by the air, which is distinguishable by the colour, it being blackish withinside when dried in the oven; and of a golden yellow, when in the air.

This root is one of the best Roman-like bitters in the materia medica; it procures an appetite, and greatly assists digestion. It has also been extolled as a febrifuge and alexipharmic, and as a certain remedy for the bite of a mad dog. On this occasion it is not only recommended internally but externally, in the form of a cataplasm, made of Venice treacle, and the powder of this root, applied to the wound. An ounce of the *gentian* root, with the same quantity of fresh lemon-peel, and a dram and a half of dried orange-peel, infused for an hour or two in three quarters of a pint of boiling water, make a very elegant bitter. The bitter tinctures are commonly prepared by macerating the above quantity of the root, for some days, in a pint of proof spirit, with four drams of dried orange-peel, and two of lesser cardamom seeds. *See Stomachic* ELIXIR.

Wines and malt liquors are likewiſe impregnated with the virtues of this root in different proportions. An ounce of the *gentian* root, the ſame quantity of freſh lemon-peel, and two drams of long pepper, communicate by maceration, without heat, a grateful warmth and bitterneſs to a quart of mountain. The virtue of the root is extracted by all theſe menſtrua, and alſo by rectified ſpirit. The tincture in rectified ſpirit is of an orange-yellow colour; inſpiſſated, it yields an intenſely bitter extract: the watery infuſions are of a dark brownish red; and leave, when inſpiſſated, an extract, in larger quantity, but leſs bitter, than the other. Theſe extracts are made into pills, with or without aromatic additions. There is an Indian *gentian* brought from America by the Portuguese, of a pale yellowiſh colour, jointed and marked with knots and circles like ipecacuanha, more intenſely bitter than any of the officinal bitter drugs. This root is greatly commended in obſtinate intermittents, and other diſorders; a ſcruple is ſaid to be more effectual than repeated half drams of bark.

There was a mixture of henbane root brought over ſome years ago with the common *gentian*, which occaſioned violent diſorders; and, in ſome inſtances, proved fatal. This root is of a paler colour than *gentian*, and its longitudinal wrinkles finer and cloſer: the poiſonous root, when cut, appears white, without any degree of the yellow hue, which is deep in *gentian*; and its taſte is not bitter, but cucumiginous. *Lewis's* Mat. Med.

GENTIAN *water*. See WATER.

GENTIANA *nigra*, a name given by ſome botanical authors to the *mountain* DAUCUS, or *black libanotis*.

GENTIANELLA, *little gentian*, a diminutive of the name *gentiana*, commonly applied to the ſmaller ſpecies of GENTIAN, or the broad-leaved Alpine gentian, with a large flower.

GENTILE, GENTILIS, a pagan, or perſon who adores falſe gods. The Hebrews applied the name גוים, *goiim*, *nations*, to all the people of the earth who were not Iſraelites or Hebrews.

Some will have it that the *gentiles* were thus called in contradiſtinction to the Jews, becauſe the latter had a poſitive law to obſerve in matters of religion, whereas the *gentiles* had only the natural law: hence they are called *gentiles*, *quia ſunt ex gente facturæ*, becauſe they remain as in a ſtate of nature.

The Jews apply the denomination *gentiles* much as the Chriſtians do that of infidels. St. Paul is called the *doctor*, or *apoſtle of the gentiles*, which appellation he firſt gave himſelf, Rom. xi. 13. "As I am the apoſtle of "the *gentiles*, I magnify mine office."

The calling of the *gentiles* to Chriſtianity has been predicted in the Old Teſtament, as it was accompliſhed in the New. See Piſa. ii. 8. Iſa. ii. Joel. ii. 29. Matth. viii. 11. xii. 18. Acts, xi. 18. xiii. 47, 48. xxviii. 28. Rom. i. 5. iii. 29. xi. 12, 13, 25. Eph. ii. 11. Rev. xi. 2. xxii. 2.

GENTILE, GENTILIS, in the Roman *Laws* and *Hiſtory*, a name which ſometimes expreſſes thoſe whom the Romans otherwiſe call *Barbarians*; whether they were allies of Rome, or not. In which ſenſe the word occurs in Ammianus, Auſonius, and the Notitia Imperii.

GENTILIS was alſo uſed, in a more peculiar ſenſe, for all ſtrangers, or foreigners, not ſubject to the Roman empire; as we ſee in the Theodoſian Code, in the title De Nuptiis Gentilium; where the word *gentiles* ſtands oppoſed to *provinciales*, or the inhabitants of the provinces of the empire.

The word is likewiſe uſed, in this ſenſe, in the Greek; but it was not introduced either into that, or the Latin tongue, till after Chriſtianity was eſtabliſhed; it being taken from Scripture.

GENTILITIA *jura*, among the Romans. See SACRA.

GENTILITIUS, an epithet uſed by ſome authors, to expreſs DISEASES, propagated from father to ſon, and running through whole families; ſuch as are more uſually called hereditary diſorders. Such is the gout very frequently, and often many others.

GENTILE *ſtone*, in *Mineralogy*, a name given by our miners in Suſſex, to a kind of iron ore found in conſiderable plenty in that county, and very readily running in the fire, though not over rich in metal. It is a ſtoney ſubſtance, and lies in ſeveral parts of that country in form of a moderately thick ſtratum. It is of a duſky brown colour, and in ſome places much paler than in others. It hath always a great number of glittering ſpangles in it, and very often contains foſſile ſhells, and other extraneous ſubſtances in it.

GENTLEMAN, a perſon of good family, or deſcended of a family which has long borne arms, the grant of which adds gentility to a man's family.

The word is formed of the French *gentilhomme*, or rather of *gentil*, *fine*, *faſhionable*, or *becoming*; and the Saxon *man*, q. d. *homo fut*, or *humilis hic natus*. The ſame ſignification has the Italian *gentilhuomo*, and the Spaniſh *hidalgo*, or *hija dalga*, that is, the ſon of ſomebody, a perſon of note. If we go farther back, we find *gentleman* originally derived from the Latin *gentilis*, which was uſed among the Romans for a race of perſons, of the ſame name, born of free or ingenuous parents, and whoſe anceſtors had never been put to death by law. Thus Cicero, in his Topics, *gentiles ſunt, qui inter ſe eodem ſunt nomine ab ingenuis oriundi, quorum majorum nemo ſervitutem ſervivit, quos capite non ſunt deminuti*, &c. Some hold, that it was formed from *gentile*, i. e. *pagan*; and that the ancient Franks, who conquered Gaul, which was then converted to Chriſtianity, were called *gentiles* by the natives, as being yet heathens. Others relate, that towards the declenſion of the Roman empire, as recorded by Ammianus Marcellinus, there were two companies of brave ſoldiers; the one called *gentilium*, and the other *ſtatariorum*; and that it was hence we derived the names *gentleman* and SQUIRE. This ſentiment is confirmed by Paſquier, who ſuppoſes the appellation *gentiles* and *ſtatari* to have been tranſmitted to us from the Roman ſoldiery; it being to the *gentiles* and *ſtatarii*, who were the braveſt of the ſoldiery, that the principal benefices, and poſſeſſions of lands, were aſſigned. See BENEFICE. The Gauls obſerving, that, during the empire of the Romans, the *ſtatarii* and *gentiles* had the beſt tenements, or appointments, of all the ſoldiers on the frontiers of the provinces, became inſenſibly accuſtomed to apply the ſame names, *gentilhommes*, and *eſcuyers*, to ſuch as they found their kings gave the beſt proviſions or appointments to. Paſq. Rech. lib. ii. cap. 15.

In ſtrictneſs, Chamberlayne obſerves, a *gentleman* is one whoſe anceſtors have been freemen, and have owed obedience to none but their prince: on which footing, no man can be a *gentleman* who is not born ſo.

Among us, the term *gentleman* is applicable to all above yeomen; ſo that noblemen may be properly called *gentlemen*.

In our ſtatutes, *gentilis homo* was adjudged a good addition for a *gentleman*, 14 Edw. III. The addition of knight is very ancient; but that of eſquire, or *gentleman*, was rare, before 1 Hen. V.

We read that J. Kingſton was made a *gentleman* by king Richard II.

As it may juſtly be aſked, what conſtitutes a *gentleman* with us? the reply is eaſy; being a *gentleman*, is being entitled to bear arms. And Mr. Camden obſerves, that the diſtinction of a *gentleman* of coat-armour, or an upſtart, and a *gentleman* of blood, is the bearing of arms from the grandfather; and that he who bears arms from his grandfather, is to all intents and purpoſes a *gentleman* of blood; for which cauſe it is requiſite by the ſtatutes of the Bath, that every knight before his admiſſion, proves himſelf to be ſo qualified; which done it carries with it, if his merit be equal, a paſſport alſo to the order of the Garter. Notitia Anglicana, p. 24. See alſo Doddridge's Honour's Pedigree, p. 247. Smith. De Republ. Angl. & Forteſcue, fol. 82.

Guillim, in his chapter of *Gentlemen*, ſays, that they have their beginning either of blood, as being born of worſhipful parents; or that they have done ſomething, either in peace or war, whereby they deſerve to bear arms, and be accounted *gentlemen*. He farther ſays, chap. xxiv. if a *gentleman* be bound apprentice to a merchant or other trader, he hath not thereby loſt his gentility; and he deſires it may be remembered, for the honour of trade, that king Henry VIII thought it no diſhonour to him, when he quitted his queen, to take to his wife Anne, the daughter of Thomas Buſſen, ſome time mayor of London. To which may be added the thought, that the firſt William, who founded our royal race, was the grandſon of a tanner.

Sir Edward Coke ſays, that eſquires and *gentlemen* are only names of worſhip, and not of dignity. And before thoſe the heralds rank all colonels, ſerjeants at law, and doctors in the three learned profeſſions. See PRECEDENCE.

GENTLEMAN *uſher of the black rod*. See BLACK.

GENTLEMEN *of the bed-chamber*. See BED-CHAMBER.

GENTLEMEN *of the chapel*, are officers whoſe duty and attendance is in the royal chapel, being in number thirty; ten whereof are prieſts, and the other twenty called *clerks of the chapel*, who aſſiſt in the performance of Divine ſervice. One of the firſt ten is choſen for confeſſor of the houſhold, whoſe office it is to read prayers every morning to the houſhold ſervants; to viſit the ſick; examine and prepare communicants, and adminiſter the ſacrament.

Another, well verſed in muſic, is choſen firſt organiſt; who is maſter of the children, to inſtruct them in muſic, and what is neceſſary for the ſervice of the chapel; a ſecond is likewiſe an organiſt; a third a luteniſt; and a fourth a violiſt.

There are likewise three *vergers*, so called from the silver rods they usually carry in their hands; being a serjeant, yeoman, and groom of the velvet: the first attends the dean, and sub-dean; finds surplices, and other necessaries, for the chapel: the second has the whole care of the chapel; keeps the pews, and seats the nobility and gentry: the groom has his attendance within the chapel-door, and looks after it.

GENTLEMEN *pensioners*. See PENSIONER.

GENTLEWOMAN, GENEROSA, is a good addition for the estate and degree of a woman, as *generosus* is for that of a man; and if a *gentlewoman* be named SPINSTER in any original writ, appeal, &c. it hath been held that she may abate, and quash the same. 2 Inst 668.

GENTOOS, in *Modern History*, according to the common acceptation of the term, denote the professors of the religion of the bramins, or BRACHMANS, who inhabit the country called Hindostan, in the East Indies, from the word *han*, a *region*, and *hind* or *hindoo*; which Ferishtch, as we learn from colonel Dow's translation of his History, supposes to have been a son of Ham, the son of Noah. It is observed, however, that Hindoo is not the name by which the inhabitants originally styled themselves, but, according to the idiom of the SHANSCRITT, which they use, *jumbodeep*, from *jumboo*, a *jackall*, an animal common in their country, and *deep*, a large portion of land surrounded by the sea, or *aberiekhund*, from *khund*, i. e. a *continent*, and *aberrut*, the name of one of the first Indian rajahs. It is also observed, that they have assumed the name of Hindoos only since the æra of the Tartar government, to distinguish themselves from their conquerors, the Musfulmen. The term *Gentoo*, or *Gentu*, in the Shanscrit dialect, denotes *animal* in general, and in its more confined sense *mankind*, and is never appropriated particularly to such as follow the doctrines of Brhimi. These are divided into four great tribes, each of which has its own separate appellation; but they have no common or collective term that comprehends the whole nation under the idea affixed by the Europeans to the word *Gentoo*. Mr. Halhed, in the preface to his translation of the Code of *Gentoo* Laws, conjectures, that the Portuguese on their first arrival in India, hearing the word frequently in the mouths of the natives, as applied to mankind in general, might adopt it for the domestic appellation of the Indians themselves, or, perhaps, their bigotry might force from the word *Gentoo* a tanciful allusion to gentile or pagan. The Hindoos, or *Gentoos*, vie with the Chinese as to the antiquity of their nation. They reckon the duration of the world by four jogues, or distinct ages: the first is the Suttee jogue, or age of purity, which is said to have lasted about 3,200,000 years, during which the life of man was 100,000 years, and his stature twenty-one cubits; the second, the Tittah jogue, or the age in which one third of mankind were reprobate, which consisted of 2,400,000 years, when men lived to the age of 10,000 years; the third, the Dwapaur jogue, in which half the human race became depraved, which endured to 800,000 years, when men's lives were reduced to a thousand years; and fourthly, the Collee jogue, in which all mankind were corrupted, or rather diminished, which the word *collee* imports. This is the present æra, which, they suppose, will exhibit for 400,000 years, of which near five thousand are already past, and man's life in this period is limited to a hundred years. It is supposed by many authors, that most of the *Gentoo* SHASTERS, or Scriptures, were composed about the begining of the collee jogue; but an objection occurs against this supposition, viz. that the shasters take no notice of the deluge; to which the brahmins reply, that all their Scriptures were written before the time of Noah, and the deluge never extended to Hindostan. Nevertheless, it appears from the shasters themselves, that they claim a much higher antiquity than this; instances of which are recited by Mr. Halhed.

The doctrine of transmigration is one of the distinguishing tenets of the *Gentoos*. With regard to this subject it is their opinion, according to Mr. Holwell, that those souls which have attained to a certain degree of purity, either by the innocence of their manners, or the severity of their mortifications, are removed to regions of happiness, proportioned to their respective merits; but that those who cannot so far surmount the prevalence of bad example, and the powerful degeneracy of the times, as to deserve such a promotion, are condemned to undergo continual punishment in the animation of successive animal forms, until, at the stated period, another renovation of the four jogues shall commence, upon the dissolution of the present. They imagine six different spheres above this earth, the highest of which, called *suttee*, is the residence of Brhima, and his particular favourites. This sphere is also the habitation of those men who never uttered a falsehood, and of those women who have voluntarily burned themselves with their husbands; the propriety of which practice is expressly enjoined in the code of the *Gentoo* laws. This code, printed by the East India company in 1776, is a very curious collection of Hindoo jurisprudence, which was selected by the most experienced pundits, or lawyers, from various compilations in the Shanscrit language, who were employed for this purpose from May 1773 to February 1775; afterwards translated into the Persian idiom, and then into the English language, by Mr. Halhed.

The several institutes contained in this collection are interwoven with the religion of the *Gentoos*, and revered as of the highest authority. The curious reader will discover an astonishing similarity between the institutes of this code and many of the ordinances of the Jewish law, between the character of the bramins or priests, and the Levites; and between the ceremony of the seape-goat, under the Mosaic dispensation, and a *Gentoo* ceremony, called the *ashummed jug*, in which a horse answers the purpose of the goat. Many obsolete customs and usages alluded to in many parts of the Old Testament, may also receive illustration from the institutes of this code. It appears from the code, that the bramins, who are the priests and legislators of the country, have reigned all the secular and executive power into the hands of another cast or tribe; and no bramin has been properly capable of the magistracy since the time of the Sattee jogue, the only privilege of importance which they have appropriated to themselves is an exemption from all capital punishment; they may be degraded, branded, imprisoned for life, or sent into perpetual exile; but it is every where expressly ordained, that a bramin shall not be put to death on any account whatsoever.

We have already observed, that the Hindoos are divided into four great and original tribes, which, according to the *Gentoo* theology, proceeded from the four different members of Brhima, the supposed immediate agent of the creation under the spirit of the Almighty. These tribes are the bramins, which proceeded from his mouth, and whose office is to pray, read, and instruct; the Chehteree, which proceeded from his arms, whose office is to draw the bow, to fight, and to govern; the Bheer, proceeding from the belly or thighs, who are to provide the necessaries of life by agriculture and traffic; and the Sooder from the feet, which are ordained to labour, serve, and travel.

Few christians, says the translator of the *Gentoo* Code, have expressed themselves with a more becoming reverence of the grand and impartial designs of Providence in all its works, or with a more extensive charity towards all their fellow-creatures of every profession, than the *Gentoos*. It is, indeed, an article of faith among the brahmins, that God's all merciful power would not have permitted such a number of different religions, if he had not found a pleasure in beholding their varieties. Those who are desirous of being farther acquainted with the principles, manners, and various institutes of the *Gentoos*, may consult Holwell's Interesting historical Events, &c. 1766. Dow's History of Indostan, 4to. 1768; and the Code of *Gentoo* Laws. See also SHASTAN and VEDAM.

GENUFLEXION, of *genu*, *knee*, and *flecto*, *I bend*, the act of bowing, or bending, the knee; or rather of kneeling down.

The jesuit Rofweyd, in his Onomasticon, shews, that *genuflexion*, or kneeling, has been a very ancient custom in the church, and even under the Old Testament dispensation; and that this practice was observed throughout all the year, excepting on Sundays, and during the time from Easter to Whitsuntide, when kneeling was forbid by the council of Nice.

Others have shewn, that the custom of not kneeling on Sundays had obtained from the time of the apostles; as appears from St. Irenæus, and Tertullian; and the Æthiopic church, scrupulously attached to the ancient ceremonies, still retains that of not kneeling at divine service. The Russians esteem it an indecent posture to worship God on the knees. Add, that the Jews usually prayed standing. Rofweyd gives the reasons of the prohibition of *genuflexion* on Sundays, &c. from St. Basil, Anastasius, St. Justin, &c.

Baronius is of opinion, that *genuflexion* was not established in the year of Christ 58, from that passage in *Acts* xx. 36. where St. Paul is expressly mentioned to kneel down at prayer; but Sauzin shews, that nothing can be thence concluded.

The same author remarks, also, that the primitive Christians carried the practice of *genuflexion* so far, that some of them had worn cavities in the floor where they prayed: and St. Jerome relates of St. James, that he had contracted a hardness on his knees equal to that of camels.

GENUS, in *Algebra*. The ancient algebraists distributed their art into two *genera*, or kinds; the LOGISTIC, and SPECIOUS.

GENUS,

GENUS, in *Anatomy*. The *genus nervosum*, or nervous kind, or, as others say, the *nervous system*, is an expression pretty frequent among authors; signifying the nerves, considered as an assemblage, or system, of similar parts, distributed throughout the body.

GENUS, GENDER, in *Botany*, denotes a system, or assemblage, of several plants, agreeing in some one or more common characters in respect of the structure of certain parts; whereby they are distinguished from all other plants.

The distribution of plants into *genera*, and species, is absolutely necessary to ease the memory, and prevent its being oppressed, and overburdened with an infinity of different names. The knowlege of a *genus* comprehends, in a kind of miniature, that of all the plants belonging thereto; each being denominated from some circumstance, common to the whole kind, to save the embarrassment of so many particular names.

Something like this, even the common people do, especially in the instance of ranunculuses, &c. but in many other plants the difficulty is infinitely greater, as it is hard to find any thing in common among them, whereon to found their *genus*.

Hence botanists differ as to the manner of regulating these *genera*, and the characters whereon they are to be established. Mr. RAY's distribution, see under PLANT.

One of the late writers, Mons. Tournefort, after a long and accurate discussion, has chose, in imitation of Gesner and Columna, to regulate them by the flowers and fruit, considered together; so that all plants, which bear a resemblance in those two respects, are of the same *genus*; after which the respective differences, as to root, stem, or leaves, make the different species, or subdivisions. *See* BOTANY.

Mr. RAY made some objections to this distribution, which grew into a considerable controversy between the two authors. The question was, whether the flowers and fruits were sufficient to establish *genera*; and to determine whether a plant was of this *genus*, or that.

The same M. Tournefort introduces another higher kind of *genus*, or class, which is only regulated by the flowers. He observes, that he has never hitherto met with above fourteen different figures of flowers; which, therefore, are all that are to be retained in the memory: so that a person who has a plant in flower, whose name he does not know, will immediately see what class it belongs to, in his Elements of Botany; and the fruit appearing some days afterwards, determines its *genus* in the same book; and the other parts give its species.

It is a wonderful ease to the memory, to have only fourteen figures of flowers to retain, and, by this means, to be enabled to descend to six hundred and seventy-three *genera*, which comprehend eight thousand eight hundred and forty-six species of plants; which was the number of those then known by land and sea. The *genera* of plants, by the SEXUAL *system* of Linnæus, which is now generally adopted, are to be regulated by the FRUCTIFICATION only: so that all vegetables which agree in their parts of fructification are to be put together under one *genus*, and all that differ in those parts are to be separated. The characteristic mark of each *genus* is to be determined by the number, figure, proportion, and situation of all the parts; but as there are few *genera*, in which all the parts are constant in every one of the species, we ought, wherever it is possible, to fix upon some one single circumstance that is constant, and make it the essential character. There is, however, no one part of fructification, that can be relied on as a constant characteristic mark of all *genera*; but in *some*, one part of the fructification is found to be the most constant; and in others, another: the most constant any part of the fructification is found through the several species of any *genus*, the more it may be relied on with certainty as a characteristic mark for that *genus*. But if this characteristic mark is wanting in any particular species, caution should be observed, lest *genera* should be confounded that ought to be distinguished; and when it is observed in some species of another *genus* near akin to it, care should be taken that the *genera* are not multiplied by parting species that should really stand together. *See* Lee's Introd. to Botany, p. 154. &c.

GENUS, KIND, in *Logic* and *Metaphysics*, is that which has several species under it; or it is the origin and radix of divers species, joined together by some affinity, or common relation, between them.

Genus is a nature, or idea, so common and universal, that it extends to other general ideas, and includes them under it.

Thus, animal is said to be a *genus*, in respect of man and brute; because man and brute agree in the common nature and character of animals; to a right lined figure, of four sides, is a *genus* in respect of a parallelogram, and a trapezium; and so, likewise, is substance, in respect of substance extended, which is body; and thinking substance, which is mind.

A good definition, say the schoolmen, consists of *genus* and difference.

In the general, *genus* may be said to be a class of a greater extent than species; and which is not convertible with: for though we may say, that all body is substance, yet it cannot be said all substance is body.

Add, that whatever may be said of the *genus*, may likewise be said of the species under it; e. gr. whatever is said of *ens*, being, will equally hold of the body.

The schoolmen define the *genus logicum* to be, an universal which is predicable of several things of different species; and divide it into two kinds: the one, the *summum*, which is the highest, or most general; and has nothing above it to respect as a *genus*: the other the *subalternum*, which they likewise call *medium*.

GENUS *summum* is that which holds the uppermost place in its class, or predicament; or that which may be divided into several species, each whereof is a *genus* in respect of other species placed below it.

Thus, in the predicament of things subsisting of themselves, *substance* has the place and effect of *genus summum*, and is predicated of all the things contained in that class: for both Plato, and man, and animal, and even spirit, are properly called substance.

Accordingly, there are as many *summa genera*, as there are classes of predicaments, or categories.

GENUS, *subalternum*, is that which, being a medium between the highest *genus* and the lowest species, is sometimes considered as a *genus*, and sometimes as a species.

Thus, bird, when compared with animal, is a species, when to a crow, and eagle, or the like, it is a *genus*.

Genus, again, is divided into *remotum*, remote, where between it and its species there is another *genus*; and *proximum*, or next, where the species is immediately under it; as man under animal.

GENUS is also used for a character, or manner applicable to every thing of a certain nature, or condition. In which sense it serves to make capital divisions in divers sciences; as music, rhetoric, botany, anatomy, &c. E. gr.

GENUS, in *Music*, by the ancients called *genus melodiæ*, denotes a certain manner of subdividing the principles of melody, i. e. the consonant intervals, into their concinuous parts.

The moderns, considering the octave as the most perfect interval, and that wherein all the other concords depend in the present theory of music; the division of that interval is considered as containing the true division of the whole scale.

But the ancients went to work somewhat differently: the diatessaron, or fourth, was the least interval which they admitted as concord; and therefore they sought, first, how that might be most concinnously divided; from which they constituted the diapente, or fifth; and diapason, or octave.

The diatessaron being thus, as it were, the root, or foundation, of the scale; what they call the *genera*, kinds, arose from its various divisions; and hence they defined the *genus melodiandi*, the manner of dividing the tetrachord, and disposing its four sounds as to succession.

The Greeks constituted three such *genera* known by the names of ENHARMONIC, CHROMATIC, and DIATONIC.

The enharmonic was not subdivided, but the chromatic was divided into three species, and the diatonic into two; so that the ancients had six species, or different divisions of the fourth in use. The moderns know but four, and one of these, the enharmonic, is scarce ever met with. It does not appear that the ancients themselves could accurately define these several species. Aristoxenus left it to the ear and practice, and did not pretend to assign any true proportions in numbers. However, he has attempted to convey some idea of these *genera* and species, by supposing the fourth divided into thirty parts. That is (as Ptolemy understands him) he supposes the difference of a chord and its fourth to be divided into thirty parts: and then assigns a certain number of these parts to each interval, or division of the various species. Hence the fourth, containing two tones and a half, the tones will each have twelve parts, and the semi-tone six.

In the enharmonic, he makes the interval between the hypate and parypate, as also between the paranete and the lichanus, to be a *diesis quadrantalis*, or $\frac{1}{4}$; and from the lichanus to the nete he makes a ditonus, or $\frac{10}{30}$. So that the enharmonic divisions will be $3+3+24=30$.

In the chromaticum molle, he makes the interval between the hypate and parypate, as also from the parypate to the lichanus a triential diesis, or $\frac{2}{30}$; and from the lichanus to the nete $\frac{28}{30}$, that is, an undivided interval equal to a tone, a semitone, and a triential diesis. Hence the intervals of this species will be represented by the numbers $4+4+22=30$.

In the chromaticum hemiolium, or sesquialterum, he

makes

makes the interval from the hypate to the parypate, and from thence to the lichanus, a diesis sesquitertera, that is $\frac{7}{8}$ of the enharmonic diesis, or $4\frac{1}{2}$ parts of his division of the fourth. The remaining undivided interval is of 21 parts; being equal to a tone, a hemitone, and a quadrantal diesis. This species will be represented by the numbers, $4\frac{1}{2}+6\frac{1}{2}+21=30$; or, to avoid fractions, $9+9+42=60$.

In the chromaticum tonicum, or tonicum, he makes the interval between the hypate to the parypate, and from thence to the lichanus, a hemitone, or $\frac{7}{12}$, and from thence to the nete, a tone and a half, or $1\frac{1}{2}$. Hence the species will be expressed by the numbers, $6+6+18=30$.

In the diatonicum molle, he makes the interval between the hypate and parypate a hemitone, or $\frac{7}{8}$, from hence to the lichanus $\frac{7}{12}$, and from this to the nete $\frac{11}{24}$; so that this species will be represented by the numbers $6+9+15=30$.

In the diatonicum intensum or syntonum, the interval between the hypate and parypate, is according to him a hemitone; and between the parypate and lichanus, as also between the lichanus and nete, is a tone. Hence the expression of this species will be $6+12+12=30$.

The same divisions are in Euclid; and Ptolemy gives the like proportions from Aristoxenus, only doubling the numbers, to avoid fractions.

Aristoxenus does not pretend that the divisions he proposes are accurate. He seems to doubt of the diæresis being two tones and a half; and of its being at all measurable by any small interval, as the hemitone or diesis. He questions whether the enharmonic diesis be precisely the fourth part of a tone; or if the chromatic diesis be its third part; all which doubts are very well grounded. And it seems as if this famous musician had only proposed his divisions of the tetrachord, as approximations to convey some idea of the different species to the imagination; and not as an accurate standard to guide the voice, and hand, in singing and playing.

This is the doctrine of the ancients concerning their six species of fourths. How to reconcile this to modern notions, and with the true principles of music, might be a work of some difficulty. Dr. Pepusch has given us his opinion as to what their six species ought accurately to be. How far his opinion is deducible from the remains of the ancient musicians, has not yet been publicly shewn. We have mentioned his doctrine under the heads Chromatic, Diatonic and Enharmonic, and shall here give them in one short view.

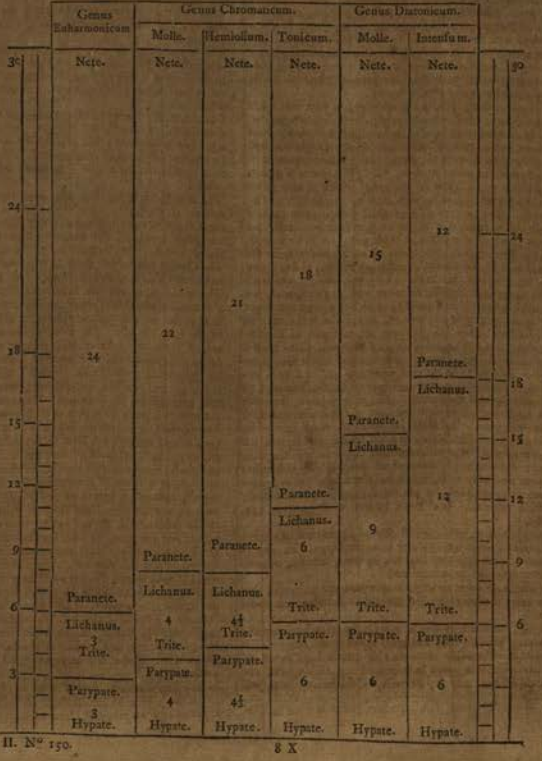
Intervals of the

Enharmonic, $1\text{v}=1+\frac{1}{2}+11$.
Chromaticum molle, $1\text{v}=1+\frac{1}{2}+(3+\frac{1}{2})$
Chromaticum sesquialterum, $1\text{v}=\frac{3}{2}+\frac{1}{2}+3$.
Chromaticum tonicum, $1\text{v}=\frac{3}{2}+\frac{3}{2}+(1+\frac{1}{2})$
Diatonicum molle, $1\text{v}=\frac{3}{2}+2+(1+\frac{1}{2})$
Diatonicum intensum, $1\text{v}=\frac{3}{2}+\frac{1}{2}+7$.

To understand which, observe, that $\frac{1}{2}$ stands for the diesis enharmonica, 1 for the semi-tone minor, $\frac{3}{2}$ for the semitone major, 2 for the tone minor, 3 for the tone major, 3 for the third minor, 11 for the third major, 1v for the fourth; and when two intervals are placed within a parenthesis, it signifies a single interval equal to the two joined by the sign of addition +. Thus $(3+\frac{1}{2})$ is an interval equal to the third minor and diesis enharmonica; $(1+\frac{1}{2})$ is equivalent to the tone major and semi-tone minor, commonly called a superfluous tone; and lastly $(7+\frac{1}{2})$ signifies a tone major and diesis enharmonica, which interval, no more than $(3+\frac{1}{2})$ has no particular name. Phil. Transf. N° 481. p. 272.

Dr. Wallis has given us a synopsis of the *genera* and species according to Aristoxenus; we shall here insert it, as it gives light to the doctrine of the ancient tetrachords.

Generum Synopsis secundum Aristoxenum.



The gradual approach of the parnete, in the different species, to the mese, shews why this chord was called ſyntonus. The length of this ſcheme, or the ſide divided into thirty parts, is ſuppoſed to be the difference of any chord, and its fourth. Ptolemy takes theſe diviſions in an aſcending fourth; that is, the longeſt of the two chords, or the whole of one chord, is terminated at hypate; and the termination of the ſhorter chord, or of that part of the long chord ſounding a fourth to the whole, is at mese. So that we muſt imagine ninety parts added upwards to this ſcheme beyond nete; and then, for inſtance, the lengths of the chords, or parts of a chord repreſenting the *diatoniſcum intenſum* of Ariſtoxenus, according to Ptolemy, will be 120, 114, 102, and 90. Ptolem. Harmon. page 92. Edit. Wallis in Opere tomiii.

But we muſt obſerve, that the ninety parts might be added downwards in the foregoing ſcheme, from hypate; and then we ſhould have a deſcending fourth expreſſed by the following numbers, 90, 96, 108, and 120, which is moſt perfectly in tune, and gives us the ſemitone major, the tone major, and the tone minor. For $\frac{15}{16}$ is the proportion of lengths of chords expreſſing the ſemitone major; $\frac{8}{9} \times \frac{15}{16} = \frac{5}{6}$ is in like manner a tone *major*; and $\frac{4}{5} \times \frac{5}{6} = \frac{2}{3}$ is the expreſſion of the tone *minor*. On the other hand, Ptolemy's numbers are much out of tune, and ſuch as a muſician like Ariſtoxenus dividing a ſtring by his ear could not fall upon. We do not know that any commentator of the ancients ever made this obſervation; but if we purſue it through all the ſpecies, we ſhall find a very ſenſible difference in the expreſſions of the proportions of the various intervals found according to Ptolemy's manner, and thoſe found in the way here mentioned, and exemplified in the diatoniſcum intenſum. Ariſtoxenus and his followers determined the ſeveral ſpecies, or diviſions of the fourth by intervals, making the whole diateſſaron equal to two tones and a half. But the Pythagoreans ſetting aſide this method, took another, whereby they ſought for three ratios, which added together would produce the ratio of 4 to 3, being the expreſſion of the fourth or diateſſaron. And as this might be variouſly done, ſo they conſtituted various differences of *genera*.

But they did not admit all ratios indiſcriminately. They chiefly regarded ſuch as were multiple and ſuperparticulars; and did not admit of the ſuperpartient, but through neceſſity, and much leſs of incommenſurable expreſſions. Ptolemy gives us ſeveral diviſions of the tetrachord, partly of his own and partly of others, which we ſhall here place in one ſhort view from Dr. Wallis's Appendix to Ptolemy's Harmonics.

$\frac{7}{8} \times \frac{11}{12} \times \frac{3}{4} = \frac{1}{2}$	Enharmonic	of Archytas.
$\frac{7}{8} \times \frac{9}{10} \times \frac{8}{9} = \frac{1}{2}$	Chromatic	
$\frac{7}{8} \times \frac{3}{4} \times \frac{8}{9} = \frac{1}{2}$	Diatonic	
$\frac{4}{5} \times \frac{11}{12} \times \frac{15}{16} = \frac{1}{2}$	Enharmonic	of Eratoſthenes.
$\frac{4}{5} \times \frac{9}{10} \times \frac{5}{6} = \frac{1}{2}$	Chromatic	
$\frac{4}{5} \times \frac{3}{4} \times \frac{5}{6} = \frac{1}{2}$	Diatonic	
$\frac{7}{8} \times \frac{11}{12} \times \frac{3}{4} = \frac{1}{2}$	Enharmonic	of Didymus.
$\frac{7}{8} \times \frac{9}{10} \times \frac{8}{9} = \frac{1}{2}$	Chromatic	
$\frac{7}{8} \times \frac{3}{4} \times \frac{8}{9} = \frac{1}{2}$	Diatonic	
$\frac{28}{33} \times \frac{33}{35} \times \frac{5}{6} = \frac{4}{7}$	Enharmonic	of Ptolemy.
$\frac{28}{33} \times \frac{11}{12} \times \frac{9}{10} = \frac{4}{7}$	Chroma molle	
$\frac{28}{33} \times \frac{11}{12} \times \frac{9}{10} = \frac{4}{7}$	—— intenſum	
$\frac{28}{33} \times \frac{33}{40} \times \frac{4}{5} = \frac{4}{7}$	Diatonum molle	
$\frac{28}{33} \times \frac{33}{40} \times \frac{4}{5} = \frac{4}{7}$	—— tenſum	
$\frac{28}{33} \times \frac{11}{12} \times \frac{3}{4} = \frac{4}{7}$	—— diuniſum	
$\frac{28}{33} \times \frac{11}{12} \times \frac{3}{4} = \frac{4}{7}$	—— intenſum	
$\frac{28}{33} \times \frac{33}{40} \times \frac{3}{4} = \frac{4}{7}$	—— æquabile	

GENUS. By the word *genus*, in *Natural Hiſtory*, we underſtand a certain analogy of a number of ſpecies making them agree together in the number, figure, and ſituation of their parts in ſuch a manner, that they are eaſily diſtinguiſhed from the ſpecies of any other *genus*, at leaſt by ſome one article. This is the proper and determinate ſenſe of the word *genus*, whereby it forms a ſubdiviſion of any claſs or order of natural beings, whether of the animal, vegetable, or mineral kingdoms, all agreeing in certain common and diſtinctive characters. See GENERICAL NAME.

GENUS, in *Rhetoric*, is one of the common places or TOPICS, and contains under it two or more ſorts of things differing in nature. See GENUS in *Logic*. Besides, authors diſtinguiſh the art of rhetoric, as alſo orations, or diſcourſes, produced thereby, into three *genera*, or kinds; *demonſtrative*, *deliberative*, and *judiciary*.

To the *demonſtrative* kind belong PANEGYRICS, EPITHALAMIUMS, *funeral harangues*, &c. To the *deliberative* kind belong perſuaſions, diſſuaſions, commendations, &c. To the *judiciary* kind belong *defences*, and *accuſations*. See RHETORIC, QUESTION, &c.

GEOCENTRIC, of γῆ, *earth*, and κέντρον, *centre*, in *Aſtronomy*, is applied to a planet, or its orbit, to expreſs it concentric with the earth: or, as having the earth for its centre, or the ſame centre with the earth.

All the planets are not *geocentric*: the moon, alone, is properly *geocentric*.

GEOCENTRIC *latitude* of a planet is its latitude ſeen from the earth; or the inclination of a line connecting the planet and the earth, to the plane of the earth's (or true) ecliptic.

Or it is the angle which the aforeſaid line (connecting the planet and the earth) makes with a line drawn to meet a perpendicular let fall from the planet to the plane of the ecliptic. See LATITUDE.

Thus in *Tab. Aſtronomy, fig.* 40. the angle ♀ *T s* is the meaſure of that planet's *geocentric* latitude, when the earth is in ♈; and the angle *e t s* the meaſure of it when the earth is in *t*.

GEOCENTRIC *place* of a planet is the place wherein it appears to us, from the earth, ſuppoſing the eye there fixed: or, it is a point in the ecliptic, to which a planet, ſeen from the earth, is referred.

GEOCENTRIC *Longitude* of a planet, is the diſtance meaſured on the ecliptic, in the order of the ſigns, between the *geocentric* place and the firſt point of Aries.

GEODÆSIA, that part of practical geometry which teaches how to diviſe, or lay out, lands, or fields, between ſeveral owners.

The word is Greek, γεωδαισία, formed of γῆ, *terra, earth*, and δαίω, *ſcindo, I divide*.

GEOMESIA is alſo applied by ſome, to all the operations of geometry which are performed in the field.

This is more uſually called SURVEYING, when employed in the meaſuring of lands, grounds, roads, countries, provinces, &c.

Varro defines *geodeſia*, the art of meaſuring ſurfaces and ſolids, not by imaginary right lines, as is done in geometry, but by ſenſible and viſible things; as by the *groma*, &c.

GEODES, in *Natural Hiſtory*, a genus of cruſtated bodies formed into large and in great part empty cells, including a ſmall quantity of earthy or ſtoneaceus matter. See SIDEROCHITA. *Tab. Foſſil, Claſs* 4.

Of this genus are five known ſpecies.

GEOFFRÆA, in *Botany*, a genus of the *decandria diandria* claſs: the calyx is parted into five ſegments, the drupe is ovated, and the nucleus compreſſed. Of this genus there is only one ſpecies.

GEOGRAPHICAL *mile* is a minute, or the ſixtieth part of a DEGREE of a great circle. See MILE.

GEOGRAPHICAL *table*. See MAP.

GEOGRAPHY, formed of γῆ, *terra, earth*, and γράφω, *ſcribo, I write, I deſcribe*, the doctrine or knowledge of the earth, both as to itſelf, and as to its affections; or a deſcription of the terreſtrial globe, and particularly of the known habitable part thereof, with all its parts.

Geography makes a branch of mathematics, of the mixed kind; becauſe it conſiders the earth, and its affections as depending on quantity; and, conſequently, as meaſurable; viz. its figure, place, magnitude, motion, celeſtial appearances, &c. with the ſeveral circles aſſigned on its ſurface.

Geography is diſtinguiſhed from coſmography, as a part from the whole; this latter conſidering the whole viſible world, both heaven and earth.

From TOPOGRAPHY, and CHOROGRAPHY, it is diſtinguiſhed, as the whole from a part.

Ptolemy conſiders *geography* as either *exterior* or *interior*: but Varenius more juſtly divides it into *general* and *ſpecial*; or *univerſal* and *particular*.

GEOGRAPHY, *general*, or *univerſal*, is that which conſiders the earth in general, without any regard to particular countries, or the affections common to the whole globe: as its figure magnitude, motion, land, ſea, &c. And this may be ſubdivided into *abſolute geography*, which reſpects the body of the earth itſelf, its parts and peculiar properties, &c. *relative*, which accounts for the appearances and accidents owing to celeſtial cauſes; and *comparative*, which explains thoſe properties, that ariſe from comparing different parts of the earth together.

GEOGRAPHY, *ſpecial*, or *particular*, is that which conſiders the conſtitution of the ſeveral particular regions, or countries; their bounds, figure, &c. with the mountains, foreſts, mines, waters, plants, and animals, &c. therein; as alſo, their climates, ſeaſons, heat, weather, diſtance from the equator, &c. and their inhabitants, arts, foods, commodities, cuſtoms, language, religion, policy, cities, &c.

Special *geography* may be ſubdivided, with regard to the ſeveral periods of its progreſs, into *ancient*, including a deſcrip-

description of the earth conformably to the knowledge which the ancients had till the decline of the Roman empire; of this kind Cellarius's Ancient Geography is an excellent summary: the *geography* of the *more* age, which extended from the fall of the Roman empire to the restoration of learning; and *modern geography*, comprehending the actual description of the earth since that time. With regard to its objects and uses, *general geography* may be divided into *natural*, which treats of the divisions and distinctions which nature has made in the surface of the globe, and the complexion, language, &c. of its inhabitants; *historical*, comprehending the different revolutions which any country or town has undergone; *civil*, or *political*, including the government of any country; *sacred*, describing those countries and places that are mentioned in scripture and ecclesiastical history; *astronomical*, giving an account of the ecclesiastical jurisdiction established and exercised in various countries; and *physical*, which considers not only the surface of the globe, but also its internal nature and substance.

Geography is very ancient, at least the special part thereof; for the ancient writers scarce went beyond the description of countries.

The Chaldeans and Egyptians, who were distinguished be their skill in geometry and astronomy, were of course the first persons that paid any particular attention to *geography*; and it is find that the first map was made by order of Sesostris I. who conquered Egypt.

It was a constant custom among the Romans, after they had conquered and subdued any province, to have a map, or painted representation thereof, carried in triumph, and exposed to the view of the spectators.

Historians relate, that the Roman senate, about a hundred years before Christ, sent geographers into divers parts, to make an accurate survey and measuration of the whole globe; but they scarce ever saw the twentieth part thereof.

Before them, Neco, king of Egypt, ordered the Phœnicians to make a survey of the whole coast of Africa; which they accomplished in three years. Darius procured the Ethiopic sea, and the mouth of the Indus, to be surveyed. Thales of Miletus, Anaximander his disciple, who is said to have constructed the first sphere; Democritus, Eudoxus, &c. who made the use of maps common in Greece; Aristagoras of Miletus, who presented to Cleomenes, king of Sparta, a table of brass, on which he had described the known earth, with its seas and rivers; and other Greeks, availing themselves of the assistance derived from the Chaldeans and Egyptians, prosecuted the study and enlarged the extent of this science. It appears that in the time of Socrates geographical maps were used at Athens, for this philosopher humbled the pride and bustle of Alcibiades, by desiring him to point out his territories in Attica in a map: and Pliny relates, that Alexander, in his expedition into Asia, took two geographers, Diogenetus and Baton, to measure and describe the roads; and that from their itineraries, the writers of the following ages took many particulars. Indeed, this may be observed, that whereas most other arts are sufferers by war, *geography* and fortification have been improved thereby.

Pytheas the famous geographer of Marseilles flourished in the time of Alexander; and Aristotle seems to have been no less conversant with *geography* than philosophy: after Alexander, Seleucus Nicanor, Theophrastus, the disciple of Aristotle, Eratosthenes, who published three books of geographical commentaries, and corrected a chart of Anaximander, Hipparchus, who corrected the observations of Eratosthenes, and thus furnished occasion for a dispute which greatly contributed to the improvement of *geography*, Agathercides of Cnidus, who lived under Ptolemy Philometor, and Mnesias, who, about fifty years after him, published a description of the whole world, Artemidorus of Ephesus, who gave a description of the earth in eleven books, often cited by Strabo and Pliny, and many others, whose names it would be tedious to enumerate, distinguished themselves by the cultivation and improvement of this science. *Geography* was transmitted, with the other arts, from Greece to Rome: Polybius, under a commission from Scipio Æmilianus, reconnoitred the coasts of Africa, Spain, and France, and measured the distances of all those places which Hannibal had visited in his march over the Pyrenees and Alps. Varro's works contain many geographical remarks; Zenodotus, Theodotus, and Polycletus were employed under the consulship of Julius Cæsar and Mark Anthony in surveying and measuring the globe. The commentaries of Cæsar are well known: Ptolemy encouraged Posidonius, who made an imperfect measurement of the earth by celestial observations, in different places under the same meridian. Augustus was a distinguished patron and promoter of this science: under whom Strabo published his *geography*. And the taste for the study and advancement of *geography* was greatly encouraged under Tiberius, Claudius, Vespasian, Domitian, and Adrian. Isidore of Charax, who lived to the commencement of the first century of the Christian æra; Pomponius Mela, who published a book entitled De Situ Orbis; Metius Pomponianus, who, having depicted the earth on a parchment, fell a sacrifice to the jealousy of Domitian, the emperor suspecting that he aimed at the empire; Pliny the naturalist, who has described the countries known in his time in the third, fourth, fifth, and sixth books of his Natural History; Marinus the Tyrian, who corrected and enlarged the discoveries of preceding geographers; and the emperor Antoninus, deserve particular mention. This abstract of the history of ancient geographers, notwithstanding whose successive labours, *geography* was still in a very imperfect state, brings us to a period, about the 150th year of the Christian æra, in which Ptolemy of Alexandria contributed greatly to the improvement of this science, by a more ample and accurate description of the terrestrial globe than any had yet given of it. He availed himself of numerous observations and ancient charts: he corrected the mistakes and supplied many defects of others; and by reducing the distances of places on the earth to degrees and minutes, after the manner of Posidonius, making use of the degrees of longitude and latitude, and settling the situation of places by astronomical observations, he reduced *geography* into a regular *system*, and laid a foundation for those further discoveries and improvements, which naturally resulted from the progressive, and at present advanced state of geometry, astronomy, navigation, and commerce. Many valuable geographical works appeared under Diocletian, Constantius, and Maximian, &c. Under the emperor Theodosius the provincial and itinerary chart or table, since known under the name of Peutinger, was digested and formed: and the last work, that ought to be classed with those of the ancients, was the Notitia Imperii, attributed to Ethicus, who lived between the years 400 and 450 of the Christian æra. The age of barbarism succeeded the fall of the Roman empire; and the arts and sciences were obliged to seek refuge and protection from the Arabians and Orientalists in Asia; the principal of whom, distinguished by their attention to *geography*, were Almamon, caliph of Babylon, and Abulfeda, a Syrian prince. After the revival of learning in Europe, and particularly during the two last centuries, *geography* has derived very considerable accessions from travels, voyages, and a variety of nautical and astronomical observations. For a fuller account of the history of ancient *geography*, see the preface to Bertius's edition of Ptolemy's Theatrum Geographiæ Veterie. Fol.

The art, however, must needs have been exceedingly defective; as a great part of the globe was then unknown: particularly all America, the northern parts of Europe and Asia, with the Terra Australis, and Magellanica; and as they were ignorant of the earth's being capable of being sailed round, and of the torrid zone's being habitable, &c.

The principal writings, in this art, among the ancients, are, Ptolemy's eight books: among the moderns are Johannes De Sacrobosco De Sphæra, with Clarius's Comment: Ricciolus's Geographia and Hydrographia Reformata: Weigelius's Speculum Terræ: De Chales's Geography, in his Mundus Mathematicus; and, above all, Varenius's Geographia generalis, with Jurin's additions: to which may be added, Leibnecht's Elementa Geographiæ generalis; Sturmius's Compendium Geographicum; Wolfius's Geographia, in his Elementa Matheseos, Gordon's, Salmon's and Guthrie's Grammars, &c.

GEOMANCY, Geomantia, a kind of divination, performed by means of a number of little points, or dots, made on paper at random; and considering the various lines and figures, which those points present; and thence forming a pretended judgment of futurity, and deciding any question proposed.

The word is formed of the Greek γη, *terra*, *earth*; and μαντια, *divination*: it being the ancient custom to cast little pebbles on the ground, and thence to form their conjectures, instead of the points afterwards made use of.

Polydore Virgil defines *geomancy* a kind of divination performed by means of clefts or chinks made in the ground; and takes the Persian Magi to have been the inventors thereof.

GEOMETRICAL, something that has a relation to *geometry*.

Thus we say a *geometrical* method, a *geometrical* genius, *geometrical* instincts, a *geometrical* construction, a *geometrical* demonstration.

Geometry itself seems to lead us into errors: after once reducing a thing to *geometrical* consideration, and finding that it answers pretty exactly, we pursue the view, are pleased with the certainty and agreeableness of the demonstrations, and apply the *geometry* further and further, till we often run into nature.

Hence it is, that all machines do not succeed: that all compositions of music, wherein the concords are the most rigidly observed, are not agreeable: that the most exact astronomical computations do not always foretel the precise time and quantity of an eclipse, &c.

The reason is, that nature is not a mere abstract mechanical levers and wheels are not *geometrical* lines and circles, as they are often supposed to be: the taste for tunes is not the same in all men; nor at all times in the same man: and as to astronomy, as there is no perfect regularity in the motions of the planets; their orbits hardly seem reducible to any fixed, known figure.

The errors, therefore, we fall into in astronomy, music, mechanics, and the other sciences to which *geometry* is applied, do not properly arise *from geometry*, which is an infallible science, but from the false use, or the misapplication of it.

GEOMETRICAL *construction* of an equation, is the contriving and drawing of lines and figures, whereby to demonstrate the equation, theorem, or canon, to be geometrically true. See CONSTRUCTION *of equations*.

GEOMETRICAL *line* or *curve*, called also *algebraic line*, or *curve*, is that wherein the relations of the abscisses to the semiordinates may be expressed by an algebraic equation. See *Algebraic* CURVES.

Geometrical lines, are distinguished into classes, orders, or genera, according to the number of the dimensions of the equation that expresses the relation between the ordinates, and the abscisses: or, which amounts to the same, according to the number of points in which they may be cut by a right line.

Thus, a line of the first order will be only a right line: those of the second, or quadratic order, will be the circle, and the conic sections; and those of the third, or cubic order, will be the cubical and Neilan parabola, the cissoid of the ancients, &c.

But a curve of the first gender (because a right line cannot be reckoned among the curves) is the same with a line of the second order; and a curve of the second gender, the same with a line of the third order; and a line of an infinitesimal order is that, which a right line may cut in infinite points; as the spiral, cyclod, the quadratrix, and every line generated by the infinite resolutions of a radius.

However, it is not the equation, but the description, that makes the curve a *geometrical* one: the circle is a *geometrical* line, not because it may be expressed by an equation, but because its description is a postulate: and it is not a simplicity of the equation, but the easiness of the description, which is to determine the choice of the lines for the construction of a problem. The equation that expresses a parabola, is more simple than that which expresses a circle; and yet the circle, by reason of its more simple construction, is admitted before it.

The circle and the conic sections, if you regard the dimensions of the equations, are of the same order; and yet the circle is not numbered with them in the construction of problems; but by reason of its simple description is depressed to a lower order; viz. that of a right line; so that it is not improper to express that by a circle, which may be expressed by a right line, but it is a fault to construct that by the conic sections, which may be constructed by a circle.

Either, therefore, the law must be taken from the dimensions of equations, as observed in a circle, and so the distinction be taken away between plane and solid problems: or the law must be allowed not to be strictly observed in lines of superior kinds; but that some, by reason of their more simple description, may be preferred to others of the same order, and be numbered with lines of inferior orders.

In constructions that are equally *geometrical*, the most simple are always to be preferred: this law is so universal as to be without exception. But algebraic expressions add nothing to the simplicity of the construction; the bare descriptions of the lines here are only to be considered; and these alone were considered by those geometricians, who joined a circle with a right line. And as these are easy or hard, the construction becomes easy, or hard; and therefore it is foreign to the nature of the thing, from any thing else to establish laws about constructions.

Either, therefore, with the ancients, we must exclude all lines besides the circle, and perhaps the conic sections, out of geometry; or admit all according to the simplicity of the descriptions: if the trochoid were admitted into geometry, we might, by its means, divide an angle in any given ratio: would you therefore blame those, who would make use of this line to divide an angle in the ratio of one number to another; and contend, that this line was not defined by an equation, but that you must make use of such lines as are defined by equations?

If, when an angle were to be divided, for instance, into 100 parts, we should be obliged to bring a curve defined by an equation of above a hundred dimensions to do the business; which nobody could describe, much less understand; and should prefer this to the trochoid, which is a line well known, and described easily by the motion of a wheel, or circle: who would not see the absurdity?

Further, therefore, the trochoid is not to be admitted at all in geometry; or else, in the construction of problems, it is to be preferred to all lines of a more difficult description; and the reason is the same for other curves.

Hence, the trisections of an angle by a conchoid, which Archimedes in his Lemmas, and Pappus in his Collections, have preferred to the invention of all others in this case, must be allowed to be good; since we must either exclude all lines, beside the circle, and right line, out of geometry, or admit them according to the simplicity of their descriptions; in which case, the conchoid yields to none, except the circle. Equations are operations of arithmetical computation, and properly have no place in geometry, except in so far as quantities truly geometrical (that is, lines, surfaces, solids, and proportions) may be said to be some equal to others: multiplications, divisions, and such sort of computations, are newly received into geometry, and that apparently contrary to the first design of this science; for whoever considers the construction of problems by a right line and a circle, found by the first geometricians, will easily perceive, that geometry was introduced that we might expeditiously avoid, by drawing lines, the tediousness of computation.

It should seem, therefore, that the two sciences ought not to be confounded together: the ancients so industriously distinguished them, that they never introduced arithmetical terms into geometry; and the moderns, by confounding both, have lost a great deal of that simplicity, in which the elegance of geometry principally consists. Upon the whole, that is arithmetically more simple, which is determined by more simple equations; but that is geometrically more simple, which is determined by the more simple drawing of lines: and in geometry, that ought to be reckoned best, which is geometrically most simple.

GEOMETRICAL *locus*, or *place*, called also simply *locus*. See LOCUS.

GEOMETRICAL *medium*. See MEDIUM.

GEOMETRICAL *method of the ancients*. It is to be observed, that the ancients established the higher parts of their *geometry* on the same principles as the elements of that science, by demonstrations of the same kind; and that they seem to have been careful not to suppose any thing done, till by a previous problem they had shewn how it was to be performed. For lest did they suppose any thing to be done that cannot be conceived, as a line or series to be actually continued to infinity, or a magnitude to be diminished till it becomes infinitely less than what it was. The elements into which they resolved magnitudes were finite, and such as might be conceived to be real. Unbounded liberties have been introduced of late, by which *geometry* which ought to be perfectly clear, is filled with mysteries. See Mac Laurin's Fluxions, Intr. p. 29. seq.

GEOMETRICAL *solidum*. See EVOLUTE, and OSCULUM.

GEOMETRICAL *pace*, is a measure consisting of five feet. See PACE, and FOOT.

GEOMETRICAL *plan*, in *Architecture*. See PLAN.

GEOMETRICAL *plane*. See PLANE.

GEOMETRICAL *progression*. See *Geometrical* PROGRESSION.

GEOMETRICAL *proportion*, called also absolutely, and simply, *proportion*, is a similitude or identity of ratios. See RATIO.

Thus, if A be to B, as C to D, they are in *geometrical* proportion: so 8, 4, 30, and 15, are *geometrical* proportionals. See PROPORTION.

GEOMETRICAL *solution* of a problem, is when the problem is directly solved according to the strict principles, and rules of geometry, and by lines that are truly *geometrical*.

In this sense we say, *geometrical* solution in contradistinction to a mechanical, or instrumental solution, where the problem is only solved by rules and compasses.

The same term is likewise used in opposition to all indirect and inadequate kinds of solutions, as by infinite series, &c.

We have no *geometrical* way of finding the quadrature of the

the circle, the duplicature of the cube, or two mean proportionals; mechanical ways and others, by infinite series, &c have.

The ancients, Pappus informs us, it vain endeavoured at the trisection of an angle, and the finding out of two mean proportionals by a right line and a circle. Afterwards they began to consider the properties of several other lines; as the conchoid, the cissoid, and the conic sections; and by some of these endeavoured to solve those problems. At length, having more thoroughly examined the matter, and the conic sections being received into geometry, they distinguished *geometrical* problems into three kinds; viz.

1. *Plane* ones, which deriving their original from lines on a plane, may be regularly solved by a right line, and a circle.

2. *Solid* ones, which are solved by lines deriving their original from the consideration of a solid; that is, of a cone.

3. *Linear* ones, to the solution of which are required lines more compounded.

According to this distinction, we are not to solve solid problems by other lines than the conic sections; especially if no other lines but right ones, a circle, and the conic sections, must be received into geometry.

But the moderns, advancing much further, have received into geometry all lines that can be expressed by equations; and have distinguished, according to the dimensions of the equations, those lines into kinds; and how much it is a law, not to construct a problem by a line of superior kind, that may be constructed by one of an inferior kind.

GEOMETRICAL *figure*. See SQUARE.

GEOMETRICAL *table*. See PLANE *table*.

GEOMETRICALLY *proportionals*, are quantities in continual proportion; or which proceed in the same constant ratio; as 6, 12, 24, 48, 96, 192, &c.

They are thus called, in contradistinction to equidifferent quantities; which are called, though somewhat improperly, *Arithmetically* PROPORTIONALS.

GEOMETRY, the science, or doctrine of extension, or extended things; that is, of lines, surfaces, or solids.

The word is Greek, γεωμετρια, formed of γη, or γεα *earth*; and μετρεω, *measure*; it being the necessity of measuring the earth, and the parts and places thereof, that gave the first occasion to the invention of the principles and rules of this art; which has since been extended and applied to numerous other things; insomuch that *geometry* with arithmetic, is now the general foundation of all mathematics.

Herodotus, lib. ii. p. 109. edit. Wesselingii, Diodorus, lib. i. § 81. or vol. i. p. 91. edit. Amst. 1746. and Strabo, lib. xvii. vol. ii. p. 1156. edit. Amst. 1707, affert the Egyptians to have been the first inventors of *geometry*; and the annual inundations of the Nile to have been the occasion of it; for that river bearing away all the bounds and land-marks of men's estates, and covering the whole face of the country, the people, by they were obliged to distinguish their lands by the consideration of their figure and quantity; and thus, by experience and habit, framed themselves a method, or art, which was the origin of *geometry*. A further contemplation of the draughts of figures of fields thus laid down, and plotted in proportion, might naturally enough lead them to the discovery of some of their excellent and wonderful properties; which speculation continually improving, the art became gradually improved, as it continues to do to this day. Josephus, however, seems to attribute the invention to the Hebrews; and others, among the ancients, make Mercury the inventor. Polyd. Virgil, de Invent. Rer. lib. i. cap. 18.

From Egypt *geometry* passed into Greece, being carried thither, as some say, by Thales; whose it was much cultivated and improved by himself, Pythagoras, Anaxagoras of Clazomenæ, Hippocrates of Chios, and Plato, who testified his conviction of the necessity and importance of *geometry* in order to the successful study of philosophy by the following inscription on the door of his academy, μηδεις αγεωμετρητος εισιτω, *let no one ignorant of geometry enter here*. About fifty years after Plato lived Euclid, who collected together all those theorems which had been invented by his predecessors in Egypt and Greece, and digested them into fifteen books, entitled the ELEMENTS *of geometry*; and those propositions which were not satisfactorily proved, he more accurately demonstrated. The next to Euclid of those ancient writers, whose works are extant, is Apollonius Pergæus, who flourished in the time of Ptolemy Euergetes, about two hundred and thirty years before Christ, and about a hundred years after Euclid. The third ancient geometer, whose writings remain, is Archimedes of Syracuse, who was famous about ten years after Apollonius.

We can only mention Eudoxus of Cnidus, Archytas of Tarentum, Philolaus, Eratosthenes, Aristæus the elder, Menæchmus, his brother, and the disciple of Plato, the two Aristæuses, Conon, Thrasidæus, Nicoteles, Leon, Theudius, Hermotimus, and Nicomedes, the inventor of the CONCHOID; besides whom, there are many other ancient geometers, to whom this science is indebted. The Greeks continued their attention to *geometry* even after they were subdued by the Romans. Whereas the Romans themselves seem to have acquainted with this science, even in the most flourishing time of their republic, that they gave the name of mathematicians, as Tacitus informs us, to those who pursued the chimeras of divination and judicial astrology. Nor were they more disposed to cultivate *geometry*, as we may reasonably imagine during the decline, and after the fall of the Roman empire. The case was different with the Greeks, among whom we find many excellent geometers since the commencement of the Christian æra, and after the translation of the Roman empire. Ptolemy lived under Marcus Antoninus; and we have extant the works of Pappus of Alexandria, who lived in the time of Theodosius; the commentary of Eutocius, the Ascalonite, who lived about the year of Christ 540, on Archimede's mensuration of a circle; and the commentary on Euclid, by Pappus, who lived under the empire of Anastasius. The consequent inundation of ignorance and barbarism was unfavourable to *geometry* as well as the other sciences; and those few who applied themselves to this science, &c. were calumniated as magicians. However, in the times of European darkness, the Arabians were distinguished as the guardians and promoters of science; and from the ninth to the fourteenth century they produced many astronomers, geometers, geographers, &c. At the revival of letters, there was scarcely one European erudite or translating and commenting on the works of the ancient geometers; and *geometry* made the progress till the time of Des Cartes, who published his *Geometry* in 1637. However, in 1635, Bonaventure Cavalerius, an Italian of the order of JESUITS, published his *Geometry of indivisibles*; Gregory St. Vincent, in 1647, published his treatise, intitled Quadratura Circuli & Hyperbolæ, a work abounding with excellent theorems and paralogisms; and Pascal, about the same time, published his treatise of the cycloid. *Geometry*, as far as it was capable of deriving aid and improvement from the arithmetic of infinites, was indebted to the labours of Fermat, Barrow, Wallis, Mercator, Brouncker, J. Gregory, Hargrave, and others; to whom we may add Newton and Leibnitz. See FLUXIONS. But Sir Isaac Newton contributed to the progress of pure *geometry* by his two treatises De Quadratura Curvarum, and Enumeratio Linearum Tertii Ordinis; for CURVES: and still further by his metaphysicable and immortal work, intitled Philosophiæ Naturalis Principia Mathematica, which will always be considered as the most extensive and successful application of *geometry* to physics. We cannot forbear transcribing in this place the compliment paid to this author by the editors of the Encyclopædia, who, considering the various monuments of the author's genius, and that he had made so principal figure before the eyes of twenty-four, are tempted, they say, to subscribe to the words of Pope, that the legacies of Newton to mankind, even celestial intelligences, and those they contemplate him as a being occupying a kind of middle station between man and themselves; or at least they cannot forbear exclaiming, *how human and profane* what a distance does there seem between one man and another!

The modern geometers are innumerable: and the names of Cotes, Mc Laurin, Simpson, &c. will always be held in esteem and veneration by those who are devoted to the study of *geometry* and mathematics.

The province of *geometry* is almost infinite: for of our ideas but may be represented to the imagination by lines, upon which they become of *geometrical* consideration; it being *geometry* alone that makes comparisons, and finds the relations of lines.

Astronomy, music, mechanics, and, in a word, all the sciences which consider things subservient to more and less, i. e. all the precise and accurate sciences may be referred to *geometry*: for all speculative truths consist only in the relation of things, and in the relations between their relations, they may be all referred to lines. Consequences may be drawn from them; and these consequences, again, being rendered sensible by lines, they become permanent objects, which may be constantly exposed to a rigorous attention and examination; and thus we have infinite opportunities both of acquiring to their certainty, and pursuing them further.

The reason for instance, why we know so distinctly, and

Geometry itself seems to lead us into errors: after once reducing a thing to *geometrical* consideration, and finding that it answers pretty exactly, we pursue the view, are pleased with the certainty and agreeableness of the demonstrations, and apply the *geometry* farther and farther, till we often run out of nature.

Hence it is, that all machines do not succeed: that all computations of music, wherein the concords are the most rigidly observed, are not agreeable: that the most exact astronomical computations do not always foretel the precise time and quantity of an eclipse, &c.

The reason is, that nature is not a mere abstract; mechanical levers and wheels are not *geometrical* lines and circles, as they are often supposed to be: the tube for tones is not the same in all men; nor at all times in the same man: and as to astronomy, as there is no perfect regularity in the motions of the planets, their orbits hardly seem reducible to any fixed, known figure.

The errors, therefore, we fall into in astronomy, music, mechanics, and the other sciences to which *geometry* is applied, do not properly arise from *geometry*, which is an infallible science, but from the false use, or the misapplication of it.

GEOMETRICAL *construction* of an equation, is the contriving and drawing of lines and figures, whereby to demonstrate the equation, theorem, or canon, to be geometrically true. See CONSTRUCTION *of equations*.

GEOMETRICAL *line* or *curve*, called also *algebraic line*, or *curve*, is that wherein the relations of the abscisses to the semiordinates may be expressed by an algebraic equation. See *Algebraic* CURVES.

Geometrical lines, are distinguished into classes, orders, or genera, according to the number of the dimensions of the equation that expresses the relation between the ordinates, and the abscisses: or, which amounts to the same, according to the number of points in which they may be cut by a right line.

Thus, a line of the first order will be only a right line: those of the second, or quadratic order, will be the circle, and the conic sections; and those of the third, or cubic order, will be the cubical and Nellian parabolas, the cissoid of the ancients, &c.

But a curve of the first gender (because a right line cannot be reckoned among the curves) is the same with a line of the second order; and a curve of the second gender, the same with a line of the third order; and a line of an infinitesimal order is that, which a right line may cut in infinite points; as the spiral, cyclood, the quadratrix, and every line generated by the infinite revolutions of a radius.

However, it is not the equation, but the description, that makes the curve a *geometrical* one: the circle is a *geometrical* line, not because it may be expressed by an equation, but because its description is a postulate: and it is not a simplicity of the equation, but the easiness of the description, which is to determine the choice of the lines for the construction of a problem. The equation that expresses a parabola, is more simple than that which expresses a circle; and yet the circle, by reason of its more simple construction, is admitted before it.

The circle and the conic sections, if you regard the dimensions of the equations, are of the same order; and yet the circle is not numbered with them in the construction of problems; but by reason of its simple description is depressed to a lower order, viz. that of a right line; so that it is not improper to express that by a circle, which may be expressed by a right line, but it is a fault to construct that by the conic sections, which may be constructed by a circle.

Either, therefore, the law must be taken from the dimensions of equations, as observed in a circle, and so the distinction be taken away between plane and solid problems; or the law must be allowed not to be strictly observed in lines of superior kinds; but that some, by reason of their more simple description, may be preferred to others of the same order, and be numbered with lines of inferior orders.

In constructions that are equally *geometrical*, the most simple are always to be preferred: this law is so universal as to be without exception. But algebraic expressions add nothing to the simplicity of the construction; the here descriptions of the lines here are only to be considered; and these alone were considered by those geometricians, who joined a circle with a right line. And as these are easy or hard, the construction becomes easy, or hard; and therefore it is foreign to the nature of the thing, from any thing else to establish laws about constructions.

Either, therefore, with the ancients, we must exclude all lines besides the circle, and perhaps the conic sections, out of geometry; or admit all according to the simplicity of the descriptions: if the trochoid were admitted into geometry, we might, by its means, divide an angle in any given ratio: would you therefore blame those, who would make use of that line to divide an angle in the ratio of one number to another; and contend, that this line was not defined by an equation, but that you must make use of such lines as are defined by equations?

If, when an angle were to be divided, for instance, into 1001 parts, we should be obliged to bring a curve defined by an equation of above a hundred dimensions to do the business; which nobody could describe, much less understand; and should prefer this to the trochoid, which is a line well known, and described easily by the motion of a wheel, or circle: who would not for the absurdity?

Either, therefore, the trochoid is not to be admitted at all in geometry; or else, in the constructions of problems, it is to be preferred to all lines of a more difficult description; and the reason is the same for other curves.

Hence, the trisections of an angle by a conchoid, which Archimedes in his Lemmas, and Pappus in his Collections, have preferred to the invention of all others in this *case*, must be allowed to be good: since we must either exclude all lines, beside the circle, and right line, out of geometry, or admit them according to the simplicity of their descriptions; in which case, the conchoid yields to none, except the circle. Equations are expressions of arithmetical computation, and properly have no place in geometry, except so far as quantities truly geometrical (that is, lines, surfaces, solids, and proportions) may be said to be some equal to others: multiplications, divisions, and such sort of computations, are newly received into geometry, and that apparently contrary to the first design of this science; for whoever considers the construction of problems by a right line and a circle, found by the first geometricians, will easily perceive, that geometry was introduced that we might expeditiously avoid, by drawing lines, the tediousness of computation.

It should seem, therefore, that the two sciences ought not to be confounded together: the ancients so industriously distinguished them, that they never introduced arithmetical terms into geometry; and the moderns, by confounding both, have lost a great deal of that simplicity, in which the elegance of geometry principally consists. Upon the whole, that is arithmetically most simple, which is determined by more simple equations; but that is geometrically most simple, which is determined by the more simple drawing of lines: and in geometry, that ought to be reckoned best, which is geometrically most simple.

GEOMETRICAL *locus*, or *place*, called also simply *locus*. See LOCUS.

GEOMETRICAL *medium*. See MEDIUM.

GEOMETRICAL *method of the ancients*. It is to be observed, that the ancients established the higher parts of their *geometry* on the same principles as the elements of that science, by demonstrations of the same kind: and that they seem to have been careful not to suppose any thing done, till by a previous problem they had shewn how it was to be performed. For less did they suppose any thing to be done that cannot be conceived, as a line or series to be actually continued to infinity, or a magnitude to be diminished till it becomes infinitely less than what it was. The elements into which they resolved magnitudes were finite, and such as might be conceived to be real. Unbounded liberties have been introduced of late, by which *geometry* which ought to be perfectly clear, is filled with mysteries. See Mac Laurin's Fluxions, Intr. p. 30, &c.

GEOMETRICAL *nisum*. See EVOLUTE, and OSCULUM.

GEOMETRICAL *pace*, is a measure consisting of five feet. See PACE, and FOOT.

GEOMETRICAL *plan*, in *architecture*. See PLAN.

GEOMETRICAL *plane*. See PLANE.

GEOMETRICAL *progression*. See *Geometrical* PROGRESSION.

GEOMETRICAL *proportion*, called also absolutely, and simply, *proportion*, is a similitude or identity of ratios. See RATIO.

Thus, if A be to B, as C to D, they are in *geometrical* proportion: so 8, 4, 30, and 15, are *geometrical* proportionals. See PROPORTION.

GEOMETRICAL *solution* of a problem, is when the problem is directly solved according to the strict principles, and rules of geometry, and by lines that are truly *geometrical*.

In this sense we say, *geometrical* solution in contradistinction to a mechanical, or instrumental solution, where the problem is only solved by ruler and compasses.

The same term is likewise used in opposition to all indirect and inadequate kinds of solutions, as by infinite series, &c.

We have no *geometrical* way of finding the quadrature of the

the circle, the duplicature of the cube, or two mean proportionals; mechanical ways, and others, by infinite fancies, &c. &c.

The ancients, Pappus informs us, in vain endeavoured at the trisection of an angle, and the finding out of two mean proportionals by a right line and a circle. Afterwards they began to consider the properties of several other lines; as the conchoid, the cissoid, and the conic sections; and by some of these endeavoured to solve those problems. At length, having more thoroughly examined the matter, and the conic sections being received into geometry, they callingallthat geometrical problems into three kinds; viz.

1. *Plane* ones, which deriving their original from lines on a plane, may be regularly solved by a right line, and a circle.

2. *Solid* ones, which are solved by lines deriving their original from the consideration of a solid; that is, of a cone.

3. *Linear* ones, to the solution of which are required lines more compounded.

According to this distinction, we are not to solve solid problems by other lines than the conic sections; especially if no other lines but right ones, a circle, and the conic sections, could be received into geometry.

But the moderns, advancing much farther, have received into geometry all lines that can be expressed by equations; and have distinguished, according to the dimensions of the equations, those lines into kinds; and have made it a law, not to construct a problem by a line of superior kind, that may be conStructed by one of an inferior kind.

GEOMETRICAL *figure*. See SQUARE.

GEOMETRICAL *locus*. See PLANE *locus*.

GEOMETRICALLY *proportionals*, are quantities in continual proportion; or which proceed in the same constant ratio; as 6, 12, 24, 48, 96, 192, &c.

They are thus called, in contradistinction to equidifferent quantities; which are called, though somewhat improperly, *Arithmetically* PROPORTIONALS.

GEOMETRY, the science, or doctrine of extension, or extended things; that is, of lines, surfaces, or solids.

The word is Greek, γεωμετρια, formed of γη, or γεα, *earth*; and μετρεω, *measure*; it being the necessity of measuring the earth, and the parts and places thereof, that gave the first occasion to the invention of the principles and rules of this art; which has since been extended and applied to numerous other things; insomuch that *geometry* with arithmetic, is now the general foundation of all mathematics.

Herodotus, lib. II. p. 109. edit. Wesselingii, Diodorus, lib. i. 431. et vol. I. p. 91. edit. Amst. 1746. and Strabo, lib. XVII. 816. et p. 1156. edit. Amst. 1707, affert the Egyptians to have been the first inventors of *geometry*; and the annual inundations of the Nile to have been the occasion of it; for that river bearing away all the bounds and land-marks of men's estates, and covering the whole face of the country, the people, by this, were obliged to distinguish their lands by the consideration of their figure, and quantity: and thus, by experience and habit, framed themselves a method or art, which was the origin of *geometry*. A further contemplation of the draughts of figures of fields thus laid down, and plotted in proportion, might naturally enough lead them to the discovery of some of their excellent and wonderful properties; which speculation continually improving, the art became gradually improved, as it continues to do to this day. Josephus, however, seems to attribute the invention to the Hebrews; and others, among the ancients, make Mercury the inventor. Polyd. Virgil, de Invent. Rer. lib. 1. cap. 18.

From Egypt *geometry* passed into Greece, being carried thither, as some say, by Thales; where it was much cultivated and improved by himself, Pythagoras, Anaxagoras of Clazomene, Hippocrates of Chios, and Plato, who testified his conviction of the necessity and importance of *geometry* in order to the successful study of philosophy by the following inscription on the door of his academy, ΜΗΔΕΙΣ ΑΓΕΩΜΕΤΡΗΤΟΣ ΕΙΣΙΤΩ, *let no one unversed in geometry enter here*. About fifty years after Plato lived Euclid, who collected together all those theorems which had been invented by his predecessors in Egypt and Greece, and digested them into fifteen books, entitled the ELEMENTS of *geometry*; and those propositions which were not sufficiently proved, he more accurately demonstrated. The next to Euclid of those ancient writers, whose works are extant, is Apollonius Pergæus, who flourished in the time of Ptolemy Euergetes, about two hundred and thirty years before Christ, and about a hundred years after Euclid. The third ancient geometer, whose writings remain, is Archimedes of Syracuse, who was famous about ten years after Apollonius.

We can only mention Eudemus of Cnidus, Archytas of Tarentum, Philolaus, Leandrus hence Artiochus of Samos, Dinostratus, the inventor of the QUADRATRIX, Menechmus, his brother, and the disciple of Plato, the two Aristæuses, Conon, Theudius, Nicodes, Leon, Theætetus, Hermotimus, and Nicomedes, the inventor of the CONCHOID; besides whom, there are many other ancient geometers, to whom this science is indebted. The Greeks continued their attention to *geometry* even after they were subdued by the Romans. Whereas the Romans themselves were so little acquainted with this science, even in the most flourishing time of their republic, that they gave the name of mathematicians, as Tacitus informs us, to those who pursued the chimeras of divination and judicial astrology. Nor were they more disposed to cultivate *geometry*, as we may reasonably imagine during the decline, and after the fall of the Roman empire. The case was different with the Greeks, among whom we find many excellent geometers since the commencement of the Christian æra, and after the translation of the Roman empire. Ptolemy lived under Marcus Aurelius; and we have extant the works of Pappus of Alexandria, who lived in the time of Theodosius; the commentary of Eutocius, the Ascalonite, who lived about the year of Christ 540, on Archimede's mensuration of a circle; and the commentary on Euclid, by Pappus, who lived under the empire of Anastasius. The consequent inundation of ignorance and barbarism was unfavourable to *geometry* as well as the other sciences; and those few who applied themselves to this science, &c. were calumniated as magicians. However, in the times of European darkness, the Arabians were distinguished as the guardians and promoters of science; and from the ninth to the fourteenth century they produced many astronomers, geometers, geographers, &c. At the revival of letters, there was scarcely one European capable of translating and commenting on the works of the ancient geometers; and *geometry* made little progress till the time of Des Cartes, who published his *Geometry* in 1637. However, in 1635, Bonaventure Cavalerius, an Italian of the order of JESUATS, published his *Geometry of indivisibles*; Gregory St. Vincent, in 1647, published his *treatise*, intitled Quadratura Circuli & Hyperbolæ, a work abounding with excellent theorems and paralogisms; and Pascal, about the same time, published his treatise of the cycloid. *Geometry*, so far as it was capable of deriving aid and improvement from the arithmetic of infinites, was indebted to the labours of Fermat, Barrow, Wallis, Mercator, Brouncker, J. Gregory, Hopton, and others; to whom we may add Newton and Leibnitz. See FLUXIONS. But Sir Isaac Newton contributed to the progress of pure *geometry* by his two treatises De Quadratura Curvarum, and Enumeratio Linearum Tertii Ordinis; for CURVES; and still further by his inestimable and immortal work, intitled Philosophiæ Naturalis Principia Mathematica, which will always be considered as the most extensive and successful application of *geometry* to physics. We cannot forbear transcribing in this place the compliment paid to this author by the editors of the Encyclopedie, who, considering the various monuments of the author's genius, and that he had made his principal discoveries before the age of twenty-four, are tempted, they say, to subscribe to the words of Pope, that the genius of Newton attonishes even celestial intelligences, and that they contemplate him as a being occupying a kind of middle station between man and themselves; or at least they exhort further exclaiming, *Sons of men, and pygmies! what a distance does there subsist between one man and another!*

The modern geometers are innumerable: and the names of Cotes, Maclaurin, Simpson, &c. will always be held in esteem and veneration by those who are devoted to the study of *geometry* and mathematics.

The province of *geometry* is almost infinite: few of our ideas but may be represented to the imagination by lines; upon which they become of *geometrical* consideration: it being *geometry* alone that makes comparisons, and finds the relations of lines.

Astronomy, music, mechanics, and, in a word, all the sciences which consider things susceptible of more and less, i. e. all the precise and accurate sciences, may be referred to *geometry*; for all speculative truths consisting only in the relation of things, and in the relations between those relations, they may be all referred to lines. Consequences may be drawn from them; and their consequences, again, being rendered sensible by lines, they become permanent objects, which may be constantly exposed to a rigorous attention and examination; and thus we have infinite opportunities both of enquiring into their certainty, and advancing them further.

The reason for instance, why we know so distinctly, and

Geometry itself seems to lead us into errors: after once reducing a thing to *geometrical* consideration, and finding that it answers pretty exactly, we pursue the view, are pleased with the certainty and agreeableness of the demonstrations, and apply the *geometry* farther and farther, till we often run into ruin.

Hence it is, that all machines do not succeed: that all compositions of music, wherein the concords are the most rightly observed, are not agreeable: that the most exact astronomical computations do not always foretel the precise time and quantity of an eclipse, &c.

The reason is, that nature is not a mere abstract; mechanical levers and wheels are not *geometrical* lines and circles, as they are often supposed to be: the tasle for tunes is not the same to all men; nor at all times in the same man: and as to astronomy, as there is no perfect regularity in the motions of the planets; their orbits hardly seem reducible to any fixed, known figure.

The errors, therefore, we fall into in astronomy, music, mechanics, and the other sciences to which *geometry* is applied, do not properly arise from *geometry*, which is an infallible science, but from the false use, or the misapplication of it.

GEOMETRICAL *construction* of an equation, is the contriving and drawing of lines and figures, whereby to demonstrate the equation, theorem, or canon, to be geometrically true. See CONSTRUCTION *of equations*.

GEOMETRICAL *line* or *curve*, called also *algebraic line*, or *curve*, is that wherein the relations of the abscisses to the ordinates may be expressed by an algebraic equation. See *Algebraic* CURVE.

Geometrical lines, are distinguished into classes, orders, or genera, according to the number of the dimensions of the equation that expresses the relation between the ordinates, and the abscisses: or, which amounts to the same, according to the number of points in which they may be cut by a right line.

Thus, a line of the first order will be only a right line: those of the second, or quadratic order, will be the circle, and the conic sections; and those of the third, or cubic order, will be the cubical and Nelian parabolas, the cissoid of the ancients, &c.

But a curve of the first gender (because a right line cannot be reckoned among the curves) is the same with a line of the second order; and a curve of the second gender, the same with a line of the third order; and a line of an infinitesimal order is that, which a right line may cut in infinite points; as the spiral, cycloid, the quadratrix, and every line generated by the infinite revolutions of a radius.

However, it is not the equation, but the description, that makes the curve a *geometrical* one: the circle is a *geometrical* line, not because it may be expressed by an equation, but because its description is a postulate: and it is not a simplicity of the equation, but the easiness of the description, which is to determine the choice of the lines for the construction of a problem. The equation that expresses a parabola, is more simple than that which expresses a circle; and yet the circle, by reason of its more simple construction, is admitted before it.

The circle and the conic sections, if you regard the dimensions of the equations, are of the same order; and yet the circle is not numbered with them in the construction of problems; but by reason of its simple description is preferred to a lower order; viz. that of a right line: so that it is not improper to express that by a circle, which may be expressed by a right line, but it is a fault to construct that by the conic sections, which may be constructed by a circle.

Either, therefore, the law must be taken from the dimensions of equations, as observed in a circle, and so the distinction be taken away between plane and solid problems; or else we must be allowed not to be strictly observed in lines of superior kinds; but that some, by reason of their more simple description, may be preferred to others of the same order, and be numbered with lines of inferior orders.

In constructions that are equally *geometrical*, the most simple are always to be preferred: this law is so universal as to be without exception. But algebraic expressions add nothing to the simplicity of the construction; the bare descriptions of the lines here are only to be considered; and these alone were considered by those geometricians, who joined a circle with a right line. And as these are easy or hard, the construction becomes easy, or hard: and therefore it is foreign to the nature of the thing, from any thing else to establish laws about constructions.

Either, therefore, with the ancients, we must exclude all lines besides the circle, and perhaps the conic sections, out of geometry; or admit all according to the simplicity of the description: if the trochoid were admitted into geometry, we might, by its means, divide an angle in any given ratio: would you therefore blame those, who would make use of that line to divide an angle in the ratio of one number to another; and contend, that this line was not defined by an equation, but that you must make use of such lines as are defined by equations?

If, when an angle were to be divided, for instance, into 1001 parts, we should be obliged to bring a curve defined by an equation of above a hundred dimensions to do the business; which nobody could describe, much less understand; and should prefer this to the trochoid, which is a line well known, and described easily by the motion of a wheel, or circle: who would not for the difference?

Either, therefore, the trochoid is not to be admitted at all in geometry; or else, in the construction of problems, it is to be preferred to all lines of a more difficult description; and the reason is the same for other curves.

Hence, the trisections of an angle by a conchoid, which Archimedes in his Lemmas, and Pappus in his Collections, have preferred to the invention of all others in this rule, must be allowed to be good: since we must either exclude all lines, beside the circle, and right line, out of geometry, or admit them according to the simplicity of their descriptions: in which rule, the conchoid yields to none, except the circle. Equations are expressions of arithmetical computation, and properly have no place in geometry, except so far as quantities truly geometrical (that is, lines, surfaces, solids, and proportions) may be said to be some equal to others: multiplications, divisions, and such sort of computations, are newly received into geometry, and that apparently contrary to the first design of this science; for whoever considers the construction of problems by a right line and a circle, found by the first geometricians, will easily perceive, that geometry was introduced that we might expeditiously avoid, by drawing lines, the tediousness of computation.

It should seem, therefore, that the two sciences ought not to be confounded together; the ancients so industriously distinguished them, that they never introduced arithmetical terms into geometry; and the moderns, by confounding both, have lost a great deal of that simplicity, in which the elegance of geometry principally consists. Upon the whole, that is arithmetically most simple, which is determined by more simple equations; but that is geometrically most simple, which is determined by the more simple drawing of lines: and in geometry, that ought to be reckoned best, which is geometrically most simple.

The Greeks continued their attention to *geometry* even after they were subdued by the Romans. Whence the Romans themselves were so little acquainted with this science, even in the most flourishing time of their republic, that they gave the name of mathematicians, as Tacitus informs us, to those who pursued the chimeras of divination and judicial astrology. Nor were they more disposed to cultivate *geometry*, as we may reasonably imagine during the decline, and after the fall of the Roman empire. The case was different with the Greeks, among whom we find many excellent geometers since the commencement of the Christian æra, and after the translation of the Roman empire. Ptolemy lived under Marcus Antoninus; and we have extant the works of Pappus of Alexandria, who lived in the time of Theodosius; the commentary of Eutocius, the Ascalonite, who lived about the year of Christ 540, on Archimede's's menseration of a circle; and the commentary on Euclid, by Pappus, who lived under the empire of Anastasius. The consequent inundation of ignorance and barbarism was unfavourable to *geometry* as well as the other sciences; and those few who applied themselves to this science, &c. were calumniated as magicians. However, in these times of European darkness, the Arabians were ultimately of the guardians and promoters of science; and from the ninth to the fourteenth century they produced many astronomers, *geometers*, *geographers*, &c. At the revival of letters, there was scarcely one European capable of translating and commenting on the works of the ancient geometers; and *geometry* made the progress till the time of Des Cartes, who published his *Geometry* in 1637. However, in 1635, Bonaventure Cavalerius, an Italian of the order of Jesuats, published his *Geometry of Indivisibles*; Gregory St. Vincent, in 1647, published his treatise, intitled Quadratura Circuli & Hyperbolæ, a work abounding with excellent theorems and paradoxims; and Pascal, about the same time, published his treatise of the cycloid. *Geometry*, as far as it was capable of deriving an aid improvement from the arithmetic of infinites, was indebted to the labours of Fermat, Barrow, Wallis, Mercator, Brouncker, J. Gregory, Huygens, and others; to whom we may add Newton and Leibnitz. See FLUXIONS. But to Isaac Newton contributed to the progress of pure *geometry* by his two treatises De Quadratura Curvarum, and Enumeratio Linearum Tertii Ordinis; see CURVES: and still further by his inimitable and immortal work, intitled Philosophiæ Naturalis Principia Mathematica, which may almost be considered as the most extensive and masterful application of *geometry* to physics. We cannot forbear transcribing in this place the compliment paid to this author by the editors of the Encyclopedie, who, considering the various monuments of the author's genius, and that he had made his principal discoveries before the age of twenty-four, are tempted, may they not subscribe to the words of Pope, that the sagacity of Newton illumines even celestial intelligences, and that they contemplate him as a being occupying a kind of middle station between man and the deities; or at least they cannot forbear exclaiming, *how human and frail!* what a distance does there seem between one man and another!

The modern geometers are innumerable: and the names of Cotes, Maclaurin, Simpson, &c. will always be held in esteem and veneration by those who are devoted to the study of *geometry* and mathematics.

The province of *geometry* is almost infinite: few of our ideas but may be represented to the imagination by lines, upon which they become of *geometrical* consideration: it being *geometry* alone that makes comparisons, and finds the relations of lines.

Astronomy, music, mechanics, and, in a word, all the sciences which consider things as capable of more and less, i. e. all the precise and accurate sciences, are related to *geometry*: for all speculative truths consist only in the relation of things, and in the relations between those relations, they may be all referred to lines. Consequences may be drawn from them; and these consequences, again, being rendered sensible by lines, they become permanent objects, which may be constantly exposed to a rigorous attention and examination: and thus we have infinite opportunities both of enquiring into their certainty, and pursuing them further.

The reason for instance, why we know so distinctly, and

mark to precisely, the concords called *octave*, *fifth*, *fourth*, &c. is that we have learnt to express founds by lines, i. e. by chords accurately divided; and that we know, that the chord, which founds octave, is double of that with which it makes octave; that the fifth is the fesquialterate ratio, or as three or two; and so of the reſt. The ear itſelf cannot judge of ſounds with ſuch a nice preciſion; its judgements are too faint, vague, and variable, to form a ſcience. The fineſt bell tuned ear cannot diſtinguiſh many of the differences of ſounds; whence many muſicians deny any ſuch differences; as making their ſenſe their judge. Some, for inſtance, admit no difference between an octave and three ditones: and others, none between the greater and leſſer tone; the comma, which is the real difference, is inſenſible to them; and much more the ſcliſma, which is only half the comma.

It is only by reaſon, then, that we learn, that the length of the chord which makes the difference between certain ſounds, being diviſible into ſeveral parts, there may be a great number of different ſounds contained therein, uſeful in muſic, which yet the ear cannot diſtinguiſh. Whence it follows, that had it not been for arithmetic and *geometry*, we had had no ſuch thing as regular fixed muſic; and that we could only have ſucceeded in that art by good luck, or force of imagination; i. e. muſic would not have been any ſcience founded on inconteſtable demonſtrations: though we allow, that the tunes compoſed by force of genius and imagination, are uſually more agreeable to the ear, than thoſe compoſed by rules. So, in mechanics, the heavineſs of a weight, and the diſtance of the centre of that weight from the fulcrum, or point it is ſuſtained by, being ſuſceptible of plus and minus, they may both be expreſſed by lines: whence *geometry* becomes applicable thereto; in virtue whereof, infinite diſcoveries have been made, of the utmoſt uſe in life.

Geometrical lines and figures are not only proper to repreſent to the imagination the relations between magnitudes or between things ſuſceptible of more and leſs; as ſpaces, times, weights, motions, &c. but they may even repreſent things which the mind can no otherwiſe conceive, e. gr. the relations of incommenſurable magnitudes.

It muſt be obſerved, that this uſe of *geometry* among the ancients was not ſtrictly ſcientifical, as among us; but rather ſymbolical: they did not argue, or deduce things and properties unknown from lines; but repreſented or delineated by them things that were known. In effect, they were not uſed as means or inſtruments of diſcovering, but as images or characters, to preſerve, or communicate, the diſcoveries that were already made.

"The Egyptians, Gale obſerves, uſed *geometrical* figures, "not only to expreſs the generations, mutations, and "deſtructions of bodies; but the manner, attributes, "&c. of the ſpirit of the univerſe, who, diffuſing himſelf from the centre of his unity, through infinite concentric circles, pervades all bodies, and fills all ſpace. "But of all other figures they moſt affected the circle, "and triangle; the firſt, as being the moſt perfect, "ſimple, capacious, &c. of all figures; whence Her"mes borrowed it to repreſent the divine nature; de"fining God to be an intellectual circle or ſphere, whoſe "centre is every-where, and circumference no-where." See Kirch. Oedip. Ægyptiac. and Gale Phil. General. lib. ii. cap. 2.

The ancient *geometry* was confined to very narrow bounds, in compariſon of the modern. It only extended to right lines and curves of the firſt order, or conic ſections; whereas into the modern *geometry* new lines of infinitely more and higher orders are introduced.

Geometry is commonly divided into four parts, or branches; PLANIMETRY, ALTIMETRY, LONGIMETRY, and STEREOMETRY.

Geometry, again, is diſtinguiſhed into *theoretical* or *ſpeculative*, and *practical*.

The firſt contemplates the properties of continuity; and demonſtrates the truth of general propoſitions, called THEOREMS.

The ſecond applies thoſe ſpeculations and theorems to particular uſes in the ſolution of PROBLEMS.

GEOMETRY, *ſpeculative*, again may be diſtinguiſhed into *elementary* and *ſublime*.

GEOMETRY, *elementary* or *common*, is that employed in the conſideration of right lines, and plain ſurfaces, and ſolids generated therefrom.

GEOMETRY, *higher* or *ſublime*, is that employed in the conſideration of curve lines, conic ſections, and bodies formed thereof.

The writers who have cultivated and improved *geometry* may be diſtinguiſhed into elementary, practical, and thoſe of the ſublimer *geometry*.

The principal writers of elements, ſee enumerated under ELEMENTS.

Thoſe of the higher *geometry* are Archimedes, in his books De Sphæra, Cylindro, and Circuli Dimenſione; as alſo De Spiralibus, Conoidibus, Sphæroidibus, De Quadratura Parabolæ, and Arenarius: Kepler, in his Stereometria Nova; Cavalerius, in his Geometria Indivibilium; and Torricellius, De Solidis Sphæralibus: Pappus Alexandrinus, in Collectionibus Mathematicis; Paulus Guldinus, in his Mechanics and Statics; Barrow, in his Lectiones Geometricæ; Huygens, De Circuli Magnitudine; Bullialdus, De Lineis Spiralibus; Schooten, in his Exercitationes Mathematicæ; De Billy, De Proportione Harmonica; Ludolcus, De Cycloide; Fer. Ernell. Com. ab Harbenſtein, in Diſcrete Circulorum; Viviani, in Exercit. Mathemat. de Formatione & Menſura Fornicum; Bap. Palma, in Geomet. Exercitation. and Apoll. Pergæus, De Sectione Rationis.

For practical *geometry*, the fulleſt and completeſt treatiſes are thoſe of Mallet, written in French, but without the demonſtrations; and thoſe of Schwenter and Cantalerus, both in High Dutch. In this claſs are likewiſe to be ranked Clavius's, Tacquet's, and Ozanam's Practical Geometries; De la Hire's Ecole des Arpenteurs; Reinholdus's Geodæſia; Hartman Beyer's Stereometria; Voigtel's Geometria Subterranea; all in High Dutch: Huiſius, Galileus, Goldmannus, Scheffel, and Ozanam, on the Sector, &c.

GEOMETRY, *characteriſtic* } See { CHARACTERISTIC.
GEOMETRY, *ſpherical.* } See { SPHERICAL.

GEOMORI, Γεωμόροι, in *Antiquity*, the diviſion or claſs of the ancient Athenians, employed in agriculture.

GEOPONIC, ſomething ſalacifying or relating to AGRICULTURE. Cato, Varro, Columella, Palladius, and Pliny, are ſometimes called *geoponic* writers.

GEORGE, *St.* a name whereby ſeveral orders, both military and religious, are denominated. It took its riſe from a ſaint famous throughout all the Eaſt, called by the Greeks Μεγαλομάρτυς, q. d. *great martyr*.

On ſome medals of the emperors John and Manuel Comneni, we have the figure of *St. George* armed, holding a ſword or javelin in one hand, and in the other a buckler, with this inſcription; an O, and therein a little P
ρ, and ΓΕ—ΡΓΙΟΣ, making Ο ΑΓΙΟΣ ΓΕΟΡΓΙΟΣ, *O*
O
Holy George. He is generally repreſented on horſeback, as being ſuppoſed to have frequently engaged in combats in that manner.

He is highly venerated throughout Armenia, Muſcovy, and all the countries which adhere to the Greek rite: from the Greek, his worſhip has long ago been received into the Latin church; and England and Portugal have both choſen him for their patron ſaint.

GEORGE, *St.* is particularly uſed for an Engliſh order of knighthood, more commonly now called the *order of the Garter*. See GARTER.

GEORGE, *knights of St.* There have been various orders under this denomination, moſt of which are now extinct; particularly one founded by the emperor Frederic III. in the year 1470, to guard the frontiers of Bohemia and Hungary againſt the Turks; another, called *St. George* of Alfama, founded by the kings of Arragon; another in Auſtria and Carinthia; and another in the republic of Genoa, ſtill ſubſiſting, &c.

GEORGE, *religious of the order of St.* Of theſe there are divers orders and congregations; particularly canons regular of St. *George* in Alga, at Venice, eſtabliſhed by authority of pope Boniface IX. in the year 1404. The foundation of this order was laid by Bartholomew Colonna, who preached, in 1366, at Padua, and ſome other villages in the ſtate of Venice. Pope Pius V. in 1570, gave theſe canons precedence of all other religious. Another congregation of the ſame inſtitute in Sicily, &c.

St. GEORGE's *croſs*. See CROSS.

GEORGE *noble*, a piece of gold, current at 6s ſhillings and eight pence in the reign of king Henry VIII.

GEORGIAN *monks and nuns* are religious of Georgia, in Aſia, who follow the rule of St. BASIL.

GEORGIC, ſomething that relates to the culture or tilling of the ground.

The word is borrowed from the Latin *georgicus*, and that of the Greek γεωργικὸς, of γῆ, *terra*, *earth*; and ἔργον, *opus*, *I work*, *labour*, of ἔργω, *opus*, *work*.

The *Georgics* of Virgil are four books compoſed by that poet on the ſubject of agriculture.

GEOSCOPY, a kind of knowledge of the nature and qualities of the ground or ſoil, gained by viewing and conſidering it.

The word is formed of the Greek γῆ, *earth*, and σκοπέω, *I ſee, view*.

Geoffroy is only conjectural; but its conjectures are very well grounded.

GEOSTATICS. See STATICS.

GERANITES, of γερανος, *a crane*, in *Natural History*, a name given by some authors to such pieces of AGATE, or any other of the semi-pellucid genus, as have round spots in them, resembling in colour the eye of a crane.

GERANIUM, *crane's bill*, in *Botany*, a genus of the *monadelphia decanderia* class. Its characters are these: the flower hath a permanent empalement, composed of five small oval leaves, and five oval or heart-shaped petals, spreading open, which are in some species equal, and in others the upper two are much larger than the three lower. It has ten ſtamina, alternately longer than each other, but shorter than the petals, and terminated by oblong ſummits. In the bottom of the flower is ſituated a five-cornered germen, which is permanent. The flower is ſucceeded by five ſeeds, each being wrapped up in the husk of the beak, where they are twiſted together at the point, ſo as to form the reſemblance of a ſtork's beak. Linnæus enumerates ſixty, and Miller forty-three ſpecies.

The common wild ſorts of this plant, and thoſe alſo which are brought to the curious from the colder climates, are hardy enough, and require little care; but the African ſpecies, and the others from hot countries, which make ſo very beautiful a figure in our green-houſes, require great care in their culture and propagation.

Theſe may be propagated by ſeed, which ſhould be ſown toward the end of March in beds of light earth, and carefully ſhading them from the ſun, and giving them frequent but gentle waterings, till they are well rooted. The mats with which theſe beds are covered are to be taken off in gentle ſhowers, and always in the hot weather at nights, that the plants may have the benefit of the dew. They ſhould remain about two months in this bed, by which time they will have taken root. Some pots of about ſeven inches wide are then to be filled with light earth, and the plants are to be carefully taken up with as much as poſſible of their own earth about them, and planted ſeverally in the middle of theſe pots; when they are to be ſet in a ſhady place, and watered at times till they have taken root. When they are well-rooted, they ſhould be ſet in a more expoſed place to harden them, and ſhould ſtand out till the middle of October; but when the mornings begin to become froſty, they muſt be removed into the green-houſe and then placed as near the windows as poſſible, and the windows ſhould be opened upon them till the weather is very cold. During the winter, they muſt be frequently watered a little at a time, and their dead leaves ſhould be pulled off. They muſt not ſtand under the ſhade of other plants, nor need any artificial heat.

Thoſe who are deſirous that their plants ſhould be large and flower ſoon, ſow the ſeeds on a moderate hot-bed in the ſpring; when they are come up, they ſhould not be drawn weak, and the pots into which they are tranſplanted ſhould be plunged into another moderate hot-bed, ſhading them from the ſun, till they have taken root, and gradually inuring them to the open air, into which they ſhould be removed in the beginning of June, and placed in a ſheltered ſituation with other exotic plants.

The ſhrubby African *geraniums* are commonly propagated by cuttings, which, planted in a ſhady border, in June or July, will take good root in five or ſix weeks; and they may then be taken up and planted in ſeparate pots, placing them in the ſhade till they have taken new root, after which they may be removed into a ſheltered ſituation, and treated as the ſeedling plants.

Geranium ſtands recommended as one of the greateſt vulneraries and aſtringents of the vegetable world, and is highly extolled for its power of ſtopping profluvia of the menſes, and hæmorrhages of all kinds. Experience confirms the truth of this, eſpecially among the poor people in the country; and it were to be wiſhed that the plant could be brought into more eſteem in the ſhops, where at preſent it is diſregarded.

GERANOS, Γερανος, *in Antiquity*, a remarkable dance performed in the feſtival called DELIA.

GERARDIA, in *Botany*, the name of a genus of plants of the *didynamia angioſpermia* claſs, the characters of which are theſe: the perianthium is compoſed of one leaf divided into five ſegments, and remains after the flower is fallen: the flower is of the labiated kind, and compoſed only of one leaf: the tube is longer than the cup, and of a cylindric figure: the upper lip is erect, plain, broad, obtuſe, and emarginated: the lower lip is bent backwards, and divided into three ſegments: the two ſide ones are long and emarginated, and the middle one ſhorter and bifid. The ſtamina are four filaments, ſomewhat ſhorter than the flower, and two of theſe are a little ſhorter than the other two. The anthers are ſmall. The germen of the piſtil is ſmall and oval. The ſtyle is ſimple and filiform, and the ſtigma is obtuſe. The fruit is an oval bivalve capſule, containing two cells, and opening at the bottom when ripe: the ſeeds are ſingle and oval. There are ſix ſpecies.

GERBERA, in *Botany*. See ARNICA.

GERESOL, in *Muſic*, one of the CLEFS.

GERFALCON, or GYRFALCON. See FALCON. This is naturally a very bold, wild and fierce bird, and is therefore very difficult to be reclaimed; but when that is done, it proves one of the very beſt kinds, and will fly at almoſt any thing. The beak of the *gerfalcon* is always blue, and the claws are remarkably long and ſtrong.

In going up to the gate, as the ſportſman expreſs it, theſe birds do not hold the ſame ſort of courſe that others do, but immediately climb up upon the train on light of the bird, and as ſoon as they have reached her, they immediately make the attack, and generally pull her down at the firſt encounter; but if not, always at the ſecond or third.

This ſort of hawk is to be fed and rewarded like the others. It is of a very fly and crafty nature, and is ſo ſlothful, that it loves to keep the caſting a long time: therefore, inſtead of cotton, it is proper to give them ſometimes a caſting of tow, and to keep them ſharp ſet. As to the reclaiming this ſort of hawk, it is only to be done by gentleneſs and kindneſs; and when ſhe has been taught to be turned looſe, ſhe is next to be learned to come to the pelts of hens or other fowl. But ſhe muſt never be ſuffered to raiſe any living fleſh, for that will be apt to draw away her love from the hand and voice. Whenever ſhe eats the falconer muſt be cloſe to her, and muſt make her eat the choiceſt pieces out of his hand. There is great care to be taken in the making theſe birds, for as they are made at firſt, ſo they are for ever; and it is a neceſſary caution, with birds of this bold and fierce nature, not to hurry over the buſineſs, but to repeat the ſame thing very often till it is perfectly fixed. See HAWK.

GERM. See GERMEN.

GERMAN, in *matters of Genealogy*, ſignifies whole, entire, or own.

Germani, quaſi eadem ſortis geniti. Feſt. Hence,

GERMAN, *brother*, denotes a brother both by the father's and mother's ſide, in contradiſtinction to uterine brothers, &c. who are only ſo by the mother's ſide.

GERMAN, *coſins*, are thoſe in the firſt or neareſt degree, being the children of brothers or ſiſters.

Among the Romans we have no inſtance of marriage between coſins *german* before the time of the emperor Claudius, when they were very frequent.

Theodoſius prohibited them under very ſevere penalties, even fine and proſcription. See CONSANGUINITY.

GERMAN *acacia, bauzar, bilis, black, cane, compoſſet, empire, flute, language, meaſures, manias.* See the ſeveral ſubſtantives.

GERMANDER, *teucrium*, in *Botany*, a genus of the *didynamia gymnoſpermia* claſs. Its characters are theſe: the empalement of the flower is of one leaf, cut into five acute equal ſegments at the top, and is permanent: the flower is of the lip kind, with one petal, having a ſhort cylindrical tube, a little incurvated at the chaps; the upper lip is erect, and deeply cut into two acute ſegments; the lower lip ſpreads, and is cut into three; the middle one is large and roundiſh, the two ſide ones acute and erect: it hath four awl-ſhaped ſtamina, which are longer than the upper lip, and are prominent between the ſegments, terminated by ſmall ſummits. It has a germen divided in four parts, ſupporting a ſlender ſtyle, crowned by two ſlender ſtigmas: the germen afterward turns to four roundiſh naked ſeeds, which ripen in the empalement. Miller enumerates nineteen, and Linnæus thirty-five ſpecies.

The ſmaller creeping *germander*, or *chamædrys minor repens*, having oval leaves with crenated cuts, foot-ſtalks, and flowers growing almoſt in whorls, grows wild in the ſouth of France and Germany; but with us it is raiſed in gardens, and flowers in June and July. The leaves and tops have been recommended as diuretic and diaphoretic. Theſe are an ingredient in many of the compoſitions of the ſhops, and are given in infuſion in fevers, in ſuppreſſions of urine, in the ſcurvy, the gout, and jaundice; and where the uſe of it is continued ſufficiently, generally with ſucceſs. The tops, gathered when the ſeeds are formed, are generally preferred to the leaves. Their doſe, in ſubſtance, is from half a dram to a dram, or more. They give out their virtues both to watery and ſpirituous menſtrua.

The water *germander*, or *ſcordium*, having oblong ſaw-indented leaves, ſitting cloſe to the branches, and flowers growing by pairs at the wings of the ſtalk which is diffuſed, grows naturally in the iſle of Ely, and other ſenny parts of England, is perennial, and flowers in July. The whole plant has an odour like that of garlic. The

leaves,

leaves, moderately and newly dried, give out their fæces and taste both to water and rectified spirit; and tinge the former of a brown tint, and the latter of a deep green colour. They are effected a great deobstruent, alexipharmic, and corroborant; and have been preferred to malignant and pestilential fevers, and even the plague itself. They are strumatic and diuretic, and are used to destroy worms. Externally they cicatrize foul ulcers, and, applied by way of cataplasm, assuage pain. They are never used alone, but mostly kept in the shops as an ingredient in the *confectio Hamech*, which, though it contains several medicines of more virtue, yet takes its name *diascordium* from it.

The *teucrium* with a trifid leaf, or the common yellow ground-pine, called also *chamæpitys pinus vulgaris*, is an annual plant, growing wild in sandy and chalky grounds in some parts of England, and flowering in July. This is a low hairy plant, with whitish chaming leaves, cut deeply into three long narrow segments, like those of the pine tree, set in pairs at the joints, and yellow labiated flowers without footstalks, and wanting the upper lip. The leaves of this plant are recommended as specifics and correctors of the nervous system, and said to be particularly serviceable in female obstructions, paralytic disorders, and when continued for a length of time, either by themselves, or with the assistance of common *germander*, in rheumatic, ischiadic, and gouty pains. The dose of the leaves dried and powdered is from half a dram to a dram. Their virtues are extracted both by water and spirit, but most perfectly by the latter. Lewis.

GERMEN, or GRAIN, that part of a seed which germinates, i. e. sprouts or shoots out the first, for the production of a new plant.

Botanists call it the FUTURE and SEED. See PLANT, SEED, and GERMINATION.

GERMINATION, the ACT of germinating; that is, of a plant's sprouting, or shooting in the ground.

Some use the word in a more extensive sense, so as likewise to include the bud shooting out of leaves, blossoms, branches, flowers, fruits, and seeds.

The modern philosophers have been very attentive to the *germination* of plants, as well as the formation of the chick in the egg.

The progress of *germination* has been very accurately observed by the curious Malpighi, in the seed of a gourd. See PLANTS, *Vegetable Nature*, and VEGETATION.

GERMINATION, *magical*, Borrichius, in his History of Chemistry, gives us some very remarkable accounts of this sort of germination; and of one in particular, for which he quotes a witness, as he says, of so great veracity and so little credulity, that he might be absolutely depended on. A quantity of powder, about the weight of a barley-corn, was put into three or four pounds of river water in a glass, and partly dissolved in it: the water was then decanted into a clean vessel, and eight ounces of crude mercury put into it, upon which the mercury shot out a multitude of filaments, or branches of silver, extending themselves over the vessel, and rising above the surface of the water; and when the liquor was poured off, this silver was found to stand the several trials of fire, and acknowledged to be pure silver. Borrichius de Orta Chemiæ.

But this is only a second-hand story, and had Borrichius himself seen it, it would have scarce been credible without some further proofs. Phil. Trans. N° 39.

GEROCOMIA, of γερων, *senex*, and κομεω, *I cherish*, a term used by the ancients for that part of medicinal practice, which treated of the proper regimen to be observed in old age.

GERONTES, in *Antiquity*, a kind of judges, or magistrates, in ancient Sparta, answering to what the Areopagites were at Athens. See ARTHODUS.

The word is formed of the Greek γερων, which signifies *old man*. Whence also the words *gerontic*, something belonging to an old man; and *Gerontica*, a famous book among the modern Greeks, containing the lives of the ancient monks. The term *gerontes* was called *senatus*, that is, assembly or council of old men.

The *gerontes* were originally instituted by Lycurgus: their number, according to some, was twenty-eight; and, according to others, thirty-two. They governed in conjunction with the King, whose authority they every moment controlled, and to watch over the interests of the people. Polybius defines their office in few words, when he says, *est ejus, ut rem regiam coercendo administret*. None were to be admitted into this office under sixty years of age, and they held it for life. They were succeeded by the EPHORI.

GEROPOGON, in *Botany*, a genus of the *syngenesia polygamia æqualis* class: the receptacle of which is formed of a bristly kind of cone, the calyx is simple, the seed is contained in the pulmone down of the disc, and has five arista or beards in the form of rays. There are two species.

GERRES, GERULI, or GERULI, in *Ichthyology*, names given by the Venetians to a fish common in that part of the world. It is the Smaris, or Maena alia of authors. Aristotle very judiciously makes it a species of the *Sparus*, and distinguishes it from the others, by its having a blue spot on each side, and the pectoral and tailfins red.

GERRIA, Ypsis, among the Greeks, wicker hurdles, resembling the Roman *cancelli*, which the soldiers held over their heads to shelter themselves.

GERSA, a word used by some authors for CERUSE, or white lead.

GERUND, in *Grammar*, a sort of tense or time, of the infinitive mood; very nice to the participle, but indeclinable.

The word is formed of the Latin *gerundium*; and that from the verb *gerere, to bear*.

The *gerund* expresses not only the time, but also the manner of an action; as, he fell in running pain.

It differs from the participle, in that it expresses the time, which the participle does not.

And from the tense properly so called, in that it expresses the manner, which the tense does not.

Grammarians are much embarrassed to settle the nature and character of the *gerund*: it is certain they are no verbs, because they do not enter any judgment or affirmation of the mind, which is the office of a verb: and besides, they have their several cases, which verbs have not.

Some, therefore, will have them to be derived from passive verbs; whose infinitive is the nominative of the verb: on this footing they do dominate their several cases, or names formed of verbs, and assuming the ordinary regimen thereof.

Thus, they say, *tempus est legendi libri, as librorum*, is as much as to say, *tempus est legere libros, sed librorum*. But others dispute this decision.

GERYON, a name given by some of the ancient chemical writers to quicksilver.

GESNERA, in *Botany*, a genus of the *didynamia angiospermia* class. Its characters are these: the flower hath one petal which is tubulous, and first bent inward, and afterwards out again, like a bugle horn; the brim is divided into five obtuse segments; it hath four stamina, which are shorter than the petal: the germen, which sits under the petal, afterward becomes a roundish capsule, with two cells filled with small seeds, which are fixed on each side the partition. There are three species natives of Jamaica, and Carthagena in New Spain.

GESNER, a name used by some of the Arabian writers for CHALCANTHUM.

GESSERIT, *among the Jews*. See QUARANTIA *Id sint gesserit*.

GESSES is the furniture belonging to a horse, or an ass.

GESTATION, the time of a woman's going with child, or the interval between conception and the birth. See FŒTUS and PREGNANCY.

GESTATION is also a term in the *Ancient Medicine*, used for a sort of exercise, by us called *carriage*.

It consisted in making the patient ride on horseback, or in a chariot, or a boat; or even in making him lie in bed, if he could not endure a more violent agitation.

Æsculapius first brought gestation and gymnic into practice. The design of gestation was to recover strength after a fever, &c. was gone.

GESTICULATION, the making of affected, indecent, or unsuitable gestures, or even of proper ones in too great numbers.

Gesticulation is a grievous fault in an orator.

GESTU *gerere*, an ancient writ, where a person's good behaviour was impeached, now out of use.

GESTURE, a motion of the body, intended to signify some idea or passion of the mind.

Quintilian defines *gesture, status corporis aptus & compositus*. *Gestures* are a kind of natural language, which forgives the use of speech in their naturally dumb. The *mimics* and pantomimes were very great professors in the style of *gesture*.

Gesture consists principally in the action of the hands and face; and may be defined, a suitable conformity of the motions of the countenance, and of several parts of the body, in speaking, to the subject matter of the discourse. See ACTION. With regard to *gesture*, it may properly be called the second part of PRONUNCIATION; in which, as the voice flows of its own accord, as it receives from the mind, so the several motions of the body ought to be accommodated to the various tone, and inflections of the voice. When the voice is even and moderate, little *gesture* is required; and nothing is more unnatural and disgusting than violent motions, or distorting upon ordinary and familiar subjects. The motions of the body should, there fore, be in proportion to the

the vehemence and energy of the expreſſion, as the natural and genuine effect of it. *Geſture* is either *natural*, or from *imitation*. The former denotes ſuch actions and motions, either of the whole body, or of ſome particular part of it, as naturally accompany our words, juſt as theſe reſult from the impreſſions of our minds. As to the whole body, it ſhould not continue long in the ſame poſition, but be conſtantly changing, with a gentle and moderate motion. As to the ſeveral parts of the body, the head is the moſt conſiderable: to lift it up too high, has the air of arrogance and pride; to ſtretch it out too far or throw it back, appears clowniſh and unmannerly; to hang it downwards on the breaſt, ſhews an unmanly baſhfulneſs and want of ſpirit; and to ſuffer it to lean on either ſhoulder, argues ſloth and indolence: in calm and ſedate diſcourſes, the head ſhould keep its natural ſtate and upright poſture, occaſionally moving, and turning gently ſometimes on one ſide, and ſometimes on the other, as occaſion requires, and then returning back to its natural poſition. It ſhould always accompany the other actions of the body, except in averſion, which is expreſſed by ſtretching out the right hand, and turning the head to the left. But nothing is more indecent than violent motions and agitations of the head.

The paſſions are principally repreſented by the countenance; and the ſeveral parts of the face contribute to the proper and decent geſture of the whole. In a calm and ſedate diſcourſe, all the features retain their natural ſituation. In ſorrow, the forehead and eye-brows lower, and the cheeks hang down: but in expreſſions of joy and cheerfulneſs, the forehead and eye-brows are expanded, the cheeks contracted, and the corners of the mouth drawn upwards. Anger and reſentment contract the forehead, draw the brows together, and thruſt out the lips: and terror elevates both the brows and forehead. To theſe natural ſigns of the paſſions the orator ſhould endeavour to conform.

The motions of the eyes require the moſt careful management; becauſe, as Cicero obſerves, other parts of the countenance have but few motions; whereas all the paſſions of the ſoul are expreſſed in the eyes by ſo many different actions, that cannot poſſibly be repreſented by any *geſture* of the body, if the eyes be kept in a fixed poſture. De Orat. lib. iii cap. 59. Thus, in ſpeaking on pleaſant and delightful ſubjects, the eyes are briſk and chearful; but they ſink and are languid in delivering any thing melancholy and ſorrowful. In anger, the eyes diſcover a certain vehemence and intenſeneſs; in expreſſions of hatred and deteſtation, the eyes are turned either aſide or downwards: thus Virgil has expreſſed Dido's reſentment and diſdain of Æneas.

Illa ſolo fixos oculos averſa tenebat. Æn. lib. vi. ver. 469.

The eyes are alſo ſometimes turned downwards, to expreſs modeſty; and they ſhould be always turned towards the object which is addreſſed. A gentle and moderate motion of the eyes is commonly moſt ſuitable, whereby they may be directed to ſome of the audience with an air of reſpect and modeſty: but their motions ought to vary, according to the different nature of the paſſions which they are deſigned to diſcover in the ſpeaker, and convey to his hearers.

The ſhoulders ſhould neither be elevated nor depreſſed: a continued motion of the arms ſhould be avoided; their action ſhould be very moderate, and follow that of the hands, which need never be idle: Quinctilian lays great ſtreſs on the action of the hands, when he ſays, "The "hands, without which all *geſture* is lame and weak, "have a greater variety of motions than can well be "expreſſed; for they are almoſt equal to our words. "Do we not deſire with them, promiſe, call, diſmiſs, "threaten, beſeech, deteſt, fear, enquire, deny? Do "not they expreſs joy, ſorrow, doubt, confeſſion, pe"nitence, meaſure, plenty, number, and time? Do "not they excite, reſtrain, prove, admire, and ſhame? "that in ſo great a variety of ſpeech among all nations "and countries, this ſeems to me the common language "of mankind." Inſt. Orat. lib. xi. cap. 3.

As all bodily motion is either upward or downward, to the right or left, forward or backward, or circular, the hands are employed by the orator in all theſe, except the laſt: and as they ſhould correſpond with our expreſſions, they ought to begin and end with them. In adminiſtration, and addreſſes to heaven, they muſt be elevated, but never raiſed above the eyes; and in ſpeaking of things below us, they are directed downwards. Side motion ſhould generally begin from the left, and terminate gently on the right: in demonſtrating, addreſſing, and on ſeveral other occaſions, they are moved forward; and in threatening, ſometimes thrown back: when the orator ſpeaks of himſelf, his right hand ſhould be gently laid on his breaſt. When no other motion is neceſſary, the hands ſhould be kept about as high as the breaſt, ſo as to make nearly a right angle with the arm. They ſhould never be ſuffered to hang down, nor to loll upon the cuſhion or bar. The left-hand ſhould never move alone, but accommodate itſelf to the motions of the right: in motions to the left, the right-hand ſhould not be carried beyond the left ſhoulder: in promiſes and expreſſions of compliment, the motion of the hands ſhould be gentle and ſlow: but in exhortations and applauſe, more ſwift. The hands ſhould be generally open; but in expreſſions of compunction and anger, they may be cloſed. Neither the breaſt nor the belly ſhould be thruſt out; the trunk ſhould be eaſy and flexible, ſuiting itſelf to the motions of the head and hands; and the feet ſhould be kept ſteady.

There are other *geſtures*, which ariſe from *imitation*; as when the orator deſcribes ſome action, or perſonates another ſpeaking: but here he ſhould be careful not to overact his part, by running into any ludicrous or theatrical mimicry, or changing his action or voice in a manner unſuitable to his own character. See further on this ſubject, Ward's Oratory, vol. ii. p. 344, &c. p. 360, &c. Sheridan's Lect. on Elocution, lect vii. p. 113, &c. See alſo ACTION, IMITATION, PRONUNCIATION, and VOICE.

GESTUS *bonus*, in *Law*. See GOOD *a-bearing*.

GETHYLLIS, in *Botany*, the name of a genus of plants of the *decandria monogynia* claſs; the characters of which are theſe: the cup is a ſpatha of the lanceolated form, compoſed of one membranaceous inflated leaf, and containing only one flower; the flower conſiſts of one petal; its tube is extremely ſlender and long; the limb is plain, and is divided into ſix equal ſegments of lanceolated form, which are of about a third part of the length of the tube; the ſtamina are either twelve or eighteen ſetaceous filaments ſtanding in the cup; they are ſhort and erect, and the antheræ are oblong: the germen of the piſtil is oblong, and ſtands low in the ſpatha under the baſe of the flower; the ſtyle is capillary, and of the length of the ſtamina, and the ſtigma is trifid and obtuſe: the fruit is an oblong, inflated, triangular capſule, containing three cells, in which are numerous ſeeds. There is one ſpecies.

GEUM, in *Botany*, *Avens*, or *Herb Bennet*. See HERB *Bennet*.

GEZIRA *cubrei*, in the *Alfareia Medica* of the ancients, a name given to talc, by Avicenna, Serapion, and others. Theſe authors do not give any explication of what ſort of ſubſtance they mean by this name, but ſeem to ſuppoſe it a thing univerſally known, and only give a liſt of its qualities.

GHALGHULUWA, in *Zoology*, the Ceyloneſe name of a ſpecies of Eaſt Indian ſerpent, a ſnake of a pale brown, variegated with tranſverſe ſtreaks of white, and found among rocks and ſtones.

GHAN, is a name given in Muſcovy to CARAVANSERAI.

GHEMARA. See GEMARA.

GHERKINS. See GURKINS.

GIAGH, or JEHAGH, a cycle of twelve years, in uſe among the Turks and Cathayans.

Each year of the *giagh* bears the name of ſome animal: the firſt, that of a mouſe; the ſecond that of a bullock; the third, of a lynx or leopard; the fourth, of a hare; the fifth, of a crocodile; the ſixth, of a ſerpent; the ſeventh, of a horſe; the eighth, of a ſheep; the ninth, of a monkey; the tenth, of a hen; the eleventh, of a dog; and the twelfth, of a hog.

They alſo divide the day into twelve parts, which they call *giaghi*, and diſtinguiſh them by the names of the ſame animals. Each *giagh* contains two of our hours, and is divided into eight *keh*, as many as there are quarters of hours in our day.

GIALLOLINO, in *Natural Hiſtory*, a ſpecies of yellow ochre uſed in painting, and called in the colour-ſhops, Naples yellow. It is uſed both as an oil and a water-colour, and likewiſe in enamelling and caſtile painting, and the colouring of china-ware. Dr. Hill. Hiſt. of Foſſ. p. 56. conſiders it as a kind of bolar earth, impregnated with a ferruginous calx, and deſcribes it as a very beautiful earth, of a bright and elegant yellow, between a gold and ſaffron colour, and of a very looſe, ſpongy, porous, and ſhattery texture. It is remarkably heavy, of a duſty ſurface, and gritty to the touch; it breaks eaſily between the fingers, and ſtains the hands. It adheres but ſlightly to the tongue, and makes a very briſk fermentation with aqua fortis. It is found in ſome parts of Italy, particularly about Naples, whence it is ſaid to have its common name. It ſometimes, ſays Dr. Hill, lies on the ſurface of the earth, and in other places is dug at great depths. Others have ſuppoſed that it is one of the numerous heterocline productions of the fire in Mount Veſuvius. But M. Fougeroux has lately demonſtrated, that it is produced by art; the perſon who pre-

pores it at Naples, scrupulously observes every circumstance that might lead to a discovery of its nature and preparation, which are known only to himself. M. Fougeroux has, however, found that it contains an abundant earth, a vegetable acid, united with lead, an aluminous and ammoniacal salt, and a calx of antimony. Accordingly, on mixing together intimately twelve ounces of cerufs or white lead, one of alum, one of sal ammoniac, and three ounces of diaphoretic antimony, in an unglazed earthen pan covered over, and exposing the mixture to the heat of a moderate fire, during the space of seven or eight hours, he obtained a substance of the same colour with the *giallolino*, and possessing all its properties; as he has been assured by the most able painters who have used it, and have found no difference between it and the true Naples yellow. Hist. Acad. Sciences, 1766.

GIANT, *gigas*, a man of extraordinary, enormous stature and bulk.

The reality of *giants*, and of nations of *giants*, is much controverted among the learned. Travellers, historians, and relations, both sacred and profane, furnish various instances thereof; a great part of which naturalists and antiquaries set aside.

Those among the ancients who speak of *giants*, as historians, and affirm there were such things, are Cæsar, De Bello Gallico, lib. 1. Tacitus, De Moris Germanor. and Aulus Gellius, lib. iii. cap. 3. St. Augustine De Civit. Dei, lib. xv. cap. 9. and Sano-Grammaticus, at the end of his periods: among the moderns, Hieron Magius, Mistellan. de Gigantibus; Chiflagnius, De Gigantibus; Kircher, Mund. Subterran. lib. viii. sect. ii. cap. 4. and so many others, that Stephanus in his notes on Sano-Grammaticus affirms, nothing can be more extravagant than to deny or allegorize the authorities we have concerning them.

Dr. Derham observes, that though we read of *giants* before the flood, Gen. vi 4. and more plainly after it, Numb. xiii. 33. yet it is highly probable the size of man has always been the same from the creation; for as to the Nephilim, Gen. vi. the ancients vary about them, some taking them for monsters of impiety, atheism, rapine, tyranny; as to those, Numb. xiii. which were evidently spoken of as men of a *gigantic* size, it is probable the fears of the spies might add thereto.

Be this as it will, it is manifest, that in both these places *giants* are spoken of as rarities and wonders of the age, out of the common stature: and such instances we have had in all ages. There are many fabulous relations: such as we take to be that of Theutobochus, who is said to have been dug up anno 1613. and to have been higher than the trophies, and risen six feet long: and no better we suppose the *giants* to have been, which Ol. Magnus gives an account of in his fifth book; such as Harthen and Starchater, among the men; and among the women, *reperta est (inquit ille) puella in lapite vinctata, mortua, undecim ulnarum & semipedis, longitudinis cadaver*. Ol. Mag. Hist. lib. x. cap. 1.

But, as for the mere credible relations of Goliath (whose height was six cubits and a span, 1 Sam. xvii 4. which according to bishop Cumberland, is somewhat above eleven feet English), of Maximinus the emperor (who was nine feet high), and others in Augustus's and other reigns, of about the same height, to which might be added the dimensions of a skeleton, dug up in the place of a Roman camp, near St. Alban's, by an urn inscribed Marcus Antonius, of which an account is given by Mr. Chesterton, who judged by the dimensions of the bones, that the person was eight feet high, Phil. Trans. N° 333. These antique examples and relations, we say, may be matched, nay outdone, with modern ones; of which we have divers in J. Ludolph. Comment. in Hist. Æthiop. lib. ii. cap. 2. sect. 22. Magius, Contingius, D. Hakewel, and others; which last speaks from Nannes, of posters and archers belonging to the emperor of China, fifteen feet high; and of others from Paschas, of ten or twelve feet high, and more. See that learned author's Apol. p. 208.

The existence of a race of men above the common stature, on the coast of Patagonia, in South America, has been the subject of dispute for the two last centuries. In one century almost all navigators, of every country, affirmed that there were such persons, and in the next the fact is denied by the greater number, and their pre-decessors are treated as timid or bootless fabulists. The Ynca Garcilasso de la Vega, in his History of Peru, relates, that, according to a tradition universally received, a number of rafts or junks came to St. Helena with a company of giants on board, of a stature so enormous, that the natives of the country were not higher than their knees; that their eyes were as broad as the bottom of a plate, and their limbs proportionably large. But these are fables, similar to those relative to the same subject in other parts of the world. See GIANTS *Island*.

Turner, the naturalist, reports that he had seen, near the river Plate, on the coast of Brasil, a race of *giants*, who went stark naked, one of whom was seven feet high; but he acknowledges that he saw no other. Ibid. The ocular witnesses on the affirmative side of the question are, Magellan, Loaisa, Sarmiento, and Nodal, among the Spaniards; Cavendish, Hawkins, and Knivet, among the English; Sebald. De Noort, Le Maire, and Spilberg, among the Dutch; and among the French, those who went in the expedition from Marseilles and St. Malos, in the year 1704.

Knivet affirms, that he measured several dead bodies, which he found buried at Port Desire, which were from fourteen to fifteen spans high; and that he had frequently seen, at Brasil, one of the Patagonians, who, though a youth, measured no less than thirteen spans; and that the English prisoners at Brasil assured him, that they had seen many men of the same gigantic stature upon the coasts of the streight: this account is also confirmed by Sebald de Welt, and Olivez de Noort. Ant. Ciafca, a commissary on board de Malte's fleet, declares that he found in the sepulchres on the coast of Patagonia, the bones of men who were between ten and eleven feet high. Nodal and sir Richard Hawkins nearly relate, that these savages were a head taller than the inhabitants of Europe, and of such a stature, that the people on board their vessels called them *giants*.

Those who bear testimony to the contrary, are Winter, the Dutch admiral Hermite, Froger in De Gennes's Narrative, and sir John Narborough. Sir Francis Drake also is silent with respect to the stature of the inhabitants of Patagonia; but Winter positively affirms, that the accounts of their being *giants* are falsehoods invented by the Spaniards. Narborough measured the skulls and the print of the feet of the savages on the coast of the streight of Magellan, which, he says, were of the common size; and he had often been companies of them at Port St. Julian, who were neither taller nor bigger than other men. However, it may be observed, in general, that the greater part of those who hold the affirmative in this question, speak of people that inhabited the desert coasts of Patagonia to the east and west; and that, on the contrary, those who hold the negative, speak of those who inhabit the streight upon the sides of the utmost point of America to the north and south. Frezier relates, not from his own knowledge, but from the testimony of eye-witnesses, that there was, at a considerable distance within the country from the coast of Chili, an Indian nation, called by their neighbours *Cauchuses*, who sometimes came down to the Spanish settlements, that were more than nine feet high, and were the same race with the Patagonians who live on the eastern coast. It appears, from various relations, that the inhabitants of the two borders of the streight are of common stature, and that the race, distinguished by the name of Patagonians, make their constant residence upon the distant coasts, scarcely accessible to any but themselves; and when European ships frequented the streight, they removed and settled in the interior part of the country: however, the current testimony of late navigators, particularly commodore Byron, captain Wallis, and captain Carteret, will put an end to the doubts that have been hitherto entertained of the existence of such persons. Commodore Byron, who visited the coast of Patagonia in 1764, speaks of the inhabitants as of a gigantic stature; but he did not measure any of them, and only concluded, by the proportion of their stature to his own and that of his companions, that they could not be less than six and a half, or seven feet in height, and proportionably strong and bulky. Captain Wallis had an interview with these people in 1766, and found by measuring them, that the stature of the greater part of them was from five feet ten inches to six feet, though there were some who were six feet five, and six feet six inches, and one who was six feet seven inches. Captain Carteret, who attended captain Wallis on this occasion, confirms the above account in his letter to Dr. Mayr. See Phil. Trans. vol. lx. art. 20. 20. See Hawkesworth's Voyag. vol. i. Introd. and p. 28. 154.

GIANTS, *veteres*, in *classical Mythology*, were the sons of Terra, or the Earth, who made war against Jupiter and the celestial deities, to avenge the defeat of the Titans. These *giants* are represented as of an enormous height and size, and possessed of strength proportioned to their bulk: each of them had a hundred hands, and serpents instead of legs. Being determined to dethrone Jupiter, they seized Mount Ossa upon Pelion, and Olympus upon Ossa, and from thence attacked the gods with huge rocks, some of which fell into the sea and became islands, and others

others fell on the earth and formed mountains. Jupiter summoned a council of the gods, and being informed that it was necessary to obtain the assistance of some mortal, with the advice of Pallas he called up Hercules, and with the aid of this hero, exterminated the *giants* Enceladus, Polybotes, Mimas, Porphyrion, the two sons of Aloeus, Ephialtes, Otho, Eurytus, Clytius, Tyllyus, Pallas, Hippolitus, Agrius, Thoon, and Typhon, the last of whom it was more difficult to vanquish than all the others. Jupiter, having thus gained a complete victory, cast the rebels down to Tartarus, where they were to receive the full punishment of their enormous crimes: according to the accounts of some of the poets, he buried them alive under Mount Etna and different islands.

GIANTS *bones*, a name too hastily given by the vulgar to certain bones and parts of skeletons, of an enormous size, found in England and other places. Of all the numbers of these, which have been publicly shewn about as wonders in nature, not one but has proved, on examination, a bone of an elephant, or else of a whale; the first, however, is usually the case, as the bones of elephants are much more frequently found buried in the earth than those of the whale. We had not long ago the fore-fin of a whale, not fossile, but recent, taken clean from the sea, and shewn about London for the hand of a giant.

Sir Hans Sloane mentions a vertebra of the loin of a whale sent him from Oxfordshire, where it was dug up under ground, and afterwards used as a stool to sit upon, and vulgarly supposed part of a human buck-bone. Now, if the whole size of the body had been calculated from this piece, the account would have been such a size as would have far exceeded all the fabulous stories of *giants* skeletons extant in the world.

Many skeletons of this kind have been found, which have been called the skeletons of *giants*. Such are those of Philostratus, which are said to be the bones of men of twelve, twenty, and even thirty cubits high: that found in a mountain of Crete, and mentioned by Plato, forty-six cubits high; another of sixty cubits, found near Tangier in Mauritania, mentioned by Strabo, and supposed to be the skeleton of Anteus; the skeleton of Pallas, found in Rome, and said to be taller than the walls of that city; another found in England in 1572, fifty feet long. St. Austin alledges, in proof of the existence of *giants* before the flood, a grinder-tooth, which he saw on the shores of Utica, which was in reality that of an elephant. The tooth in the church of St. Christopher, at Hispalis, and the shoulder-bone of St. Christopher, preserved in a church at Venice, are of the same kind. The tooth preserved and shewn at Antwerp, is only the grinder of an elephant; and another, belonging to a skeleton which was dug up near Tunis in 1630, was sent to the learned Pieresc, who took the impression of it in wax, and comparing it with the tooth of an elephant shewn near the place, found it to be of the same shape and size. Sir Hans Sloane has given an accurate and learned account of several other mistakes on this subject, for which we must refer to the Philos. Transact. N° 404. However, Mons. Le Cat, in a memoir not long since read before the Academy of Sciences at Rouen, recites a number of instances, in which skeletons, or parts of skeletons, of an uncommon magnitude, have been found; these have been examined by anatomists, he says, and have been by them reputed real bones; and hence he infers the existence of *giants*.

GIANTS *Causeway*, a name given by the common people of the county of Antrim, in Ireland, to a vast quantity of that kind of black marble, called BASALTES, which stands in columns, and is natural to that marble, and runs out a great way into the sea.

The ignorance of the vulgar as to the nature of this stone, has occasioned this great pile of it to be supposed artificial, and the work of *giants*, once inhabitants there. But the truth is, that the basaltes, in whatever part of the world it is found, is always naturally of this figure. Whoever considers this amazing series of columns in Ireland, will be soon convinced no human hands could have formed them, and will find an accuracy in their figures, greater than could have been expected from the most curious hand. The length of the several columns, and their joints so regularly placed in series, and the nicenels of their articulations, by which no space or vacuity is left between, are wonderful.

Nature has been abundantly curious in the structure and formation of animal and vegetable bodies, but the fossils in general are left curiously put together; but this causeway of basaltes seems one of the works in this part of the creation, to which her greatest accuracy has been employed.

The single columns, of which this mass of piles consists, are sometimes octangular, sometimes of seven, or fewer sides, but, generally, from three to nine sides; and, when examined, they are found joll such as most accurately be required in the places where they stand to fill up between others, so as to leave no vacuity. Each of these columns is composed of a great many series of joints, each of which has to wyll suited to the place, that the joining appears only a crack or crevice in the stone; yet these are regularly articulated, there being always a ball on one part, and a socket in the other to receive it, so that the joints cannot slip off from one another. The triangular and square columns are fewer in number than the others, but they stand principally in the inner part of the large series, and are seldom seen, unless searched after by a curious eye.

The regular figure of the stone, composing this causeway, is not more wonderful than its quantity. Other figured stones, as crystals, spars, and the remains of animals, such as *encrinis* and *asteriæ*, are found only scattered thinly up and down; but nature has been profuse in this part of her workmanship, the whole country for many miles being full of it, and a wall made running no one knows how far into the sea: for, besides what extends from by the name of the Giants Causeway, which is full of vast extent, there are great numbers of the same pillars at distances in other places.

There are two other smaller and imperfect causeways to the left hand of the great one, and farther in the sea, a great number of rocks shew themselves at low water, which appear plainly all to consist of the same sort of columns. In going up the hill from the causeway these are found, in different places, a vast number of the same columns; but these do not stand erect, but are laid leaning upwards in different angles and directions. Beyond this hill, eastward, also, at several distances, there stand a great number of the same pillars, placed straight and erect, and in clusters of different sizes. These are seen scattered, as it were, over the several parts of the hills.

One parcel of them is much admired, and called by the country people the looms or the organs. It stands in an elegant form, and faces the bottom of the hill. The columns, of which this cluster consists, are fifty in number, and they are so nicely put together, that the tallest stand in the middle, and the shorter gradually on each side of it to the end, so that they look like the pipes of a church organ viewed from the front. The tallest one of all these, which stands exactly in the centre, is forty feet high, and consists of forty-four distinct joints.

Five miles westward of the *Giants Causeway* several ranges of tall pillars, of the same kind with those of the causeway, shew themselves in clusters, and smaller piles standing for a long way on the sides of the rocks. A neighbouring church was built of the stone of some like pillars found thereabouts; and this stone, on examination, proves to be the very same with that of the pillars of the *Giants Causeway*. Other pillars have been observed at a still greater distance, so that their whole extent is not less than about eleven Irish miles, or fourteen English.

The Inland pillars differ from those which run into the sea, and are called the causeway, only in the following particulars: some of the inland pillars are much larger than those of the causeway, being two feet and a half in diameter, and among these there are only found such as have three, four, five, and six sides, none of them having yet been found to have seven or eight sides, as many of those of the causeway itself have. And finally, their inland pillars, though composed of as many joints as those of the causeway, yet have not that curious articulation of the ball and socket, but are only joined by the laying one smooth surface on another; so that a joint of a single column may be slipped off from the rest, by a considerable force pressing against it. There is something like this observable also in some of the columns of the causeway itself; for among the numbers which are joined by the ball and socket, there are some which only adhere by being applied surface to surface. This is found only in a few of the columns, however, and they always stand within the clusters, and are composed of less than seven sides. In these also the joint is not made by the application of two horizontal planes, but by such as slant, so that it looks very like the breaking of an entrochus or asteria, or some other such spurry body of extraneous or animal origin.

Great numbers of the upper ends of the columns, which compose the causeway itself, are hollowed at the top, as if intended to receive another joint with a ball at its end, or as if such a joint had fallen off from them. These hollows are of great use to the neighbouring poor, for they make a kind of salt-pans of them, and thus very easily procure themselves a kind of bay-salt in summer. They fill these little basons with sea-water at high tides, and the heat of the sun and of the stone contributing greatly to the evaporation, as well as the shallowness of the

the salow, the whole humidity is found evaporated in the time of four tides, and they take out the salt ready for use. The joints, of which these pillars consist, are generally convex at one end, and concave at the other; the full part serving as a ball for the socket of the joint next below, and the other as a socket for the ball of the joint next above. But this is not an unalterable law in their formation; for there are some joints found which are convex at both ends, and others which are concave at both ends to receive balls, or outer sockets both ways. The vast height of these straight-jointed pillars, especially of the more slender and perfect ones, is amazing. Forty feet is a very considerable height for a pillar, of perhaps less than a foot in diameter, yet this is far from being the whole real length of the pillar, for this appears above ground, but what is buried in the earth is not yet known. Some curious people have dug down eight feet at the base, and found the column run in the same shape and regularity to that depth; and there appeared no room to doubt of its having gone in reality much farther.

The joints, as we see the pillars above the surface, are usually so many in number, as the pillar is feet high; but they are not regularly each of a foot long, for they are thereof at the upper part of the columns, and run gradually longer and longer as they approach the base. This is observed both in the inland-columns, and in those of the causeway, but though the length of the joints differs, their convexities and hollows are much the same in all parts of the column.

It is to be observed, that where the top of any pillar seems complete, and no part to have been broken off, the summit of the topmost joint is usually flat and smooth, nature having provided no convexity or cavity in a part where it had no use.

There seems a very great difficulty to conceive by what means the three joints, so lately and powderous, and so perfectly distinct, and disconnected bodies from one another, could arrive at the places where they now are placed, or be carried to the tops of such high columns; but when we consider many other natural phenomena, we shall find so many things equally wonderful, that this will not appear the left a work of nature because it is beyond our comprehension.

Dr. Richard Pococke endeavours to account for the joints in these pillars, by supposing that the several parts of the pillars were at first formed either in the shape of a cylinder, with the upper end, if not both ends, of a spherical figure; or that they were either spherical or oblate spheroids. For the pillars being composed, as he imagines, of crystal of six sides, and spar of three, and of a very fine black kind, he apprehends that as the crystals and spars united, and formed an irregular body, the fine black sand filled up the interstices, and formed such cylindrical or spherical bodies in a fost state, but in this horizontal laminæ or plates like tale; because they mostly appear to be of this figure, the stones separate in such plates between the joints and those parts of the pillars which have been exposed to the weather and corroded by it appear in such plates: though in some cases these are perpendicular joints, as in a remarkable pillar which seems to be split through its whole length. It is therefore probable, says Dr. Pococke, that, when this matter was in a fluid state, and when the stratum of rock was formed, on which it was made, the fluid contiguous to the rock continued in motion; that, after a time, some of the particles of matter, which composed these pillars, being disengaged from the particles of water, ceased to move and formed the parts of these pillars, which are next to the rock, in the above mentioned figures; so much being formed only at once, or in a very short time, as extends to the first joint; and then, either by change of season, or some other accident, so much more water mixed with these particles, as prevented their continuing to form themselves into such a shape and gave the former motion; that, afterwards the decrease of the water might again be the cause of the former effect, and so on, till the pillars were formed; and the top of the last that was formed being convex, that which was formed upon it would probably be concave and adapt itself to it, either by its gravity or being soster. Whilst all were in one or other of these figures, the gravitation of the second stratum above the first joint might operate in such a manner on that which was first formed, and still soft, as to press it down; and thus eight stones being round one stone would naturally press the middle stone into the form of an octagon.

The internal substance of the stone composing these columns, is extremely hard and compact. Its grain, or grain, is so very fine, that the eye does not perceive it, unless examined very nicely, and that in the surface of a piece newly broken. It then shews itself like a very fine glittering sand, thickly interspersed among a more opake matter; the whole is heavier than almost any other simple stone; yet it contains not the least particle of any metal so far as has been discovered. It is the purest and most homogene of any stone of this country; having no extraneous matter, no fossils of the animal kind in it, such as shells, entrochi, and the like; which are well known to be very common in the various strata of stone, in Ireland, and in many other parts of the world. However, Mr. Drury, well known for his models of several stones of this causeway, and his engravings of the prospects of the causeway itself, found in one of the stones a rough pebble in the shape of an egg, about 1 of an inch long, and above an inch thick; which, when it was polished, proved to be a white cornelian.

Marbles, in general, are very subject also to cracks, which, when filled up, as they usually are with sparry matter, make a sort of white veins; but such cracks and veins are not to be seen in the marble of these columns.

It has been tried in a glass-house, and found to melt with kelp, so as to make the black glass bottles.

From these observations some have concluded, that there is an analogy between this marble and crystal in their origin and formation, as the columns of crystal are alike pure and homogeneous, alike of a regularly angular figure, and both are alike free from veins, cracks, and extraneous substances. See Philos. Trans. N° 190, 212, 241. Lowth. Abridg. vol. ii. p. 511, seq. Phil. Trans. vol. xlvii. vol. xlviii. art. 34 and 35. See also the article Tochitone.

There are other prismatic columns, similar to those above described, in our own island; particularly in the mountain of Cadeidris, near Dolgelly, in Merionethshire: where they probably form a group as in other places. Mr. Strange has given an account of two groups of prismatic basaltine columns, which he discovered in the Venetian state, in Italy; one in Monte Ricco, about seven miles nearly south from Padua, and the other in Monte del Diavolo, near San Giovanni Ilarione, about ten miles north-west of Vicenza. The form of the latter is nearly circular, resembling that of the *Giant's Causeway*; that of the former approaching more to an oblong or oval figure: the columns of San Giovanni are much about the same size, and measure about a foot in diameter; those of Monte Rosso are very unequal, some being a foot, while others scarcely exceed three inches in diameter: those of both these Venetian groups manifest all the varieties of prismatic forms observable in the *Giants Causeway*, and other such groupes; but they are commonly of five, six, or seven sides, and the hexagonal form seems mostly to prevail. The texture of the former sort is solid and uniform; the surface smooth, and the internal parts of a dark iron-grey colour; those of Monte Rosso have a rough and knotty surface; and, when broken, manifest a variegated colour, and unequal texture of parts; resembling an inferior sort of granite, of which the mountain is formed, and which serves as a base for this range of columns.

Other groups of articulated basaltine columns have also been observed in the province of Velay and Auvergne in France; particularly by M. De Varennes, at Blaud near Langeac, and by M. Desmarests, near le Mont d'Or; and M. Sage mentions another near St. Alcon, in the same province. Kircher has long ago described a group of the same columns near Viterbo in Italy. Mundus Subterran. lib. viii. § i. cap. 9, &c. And Mr. Strange mentions another at Cassel Nuovo, in the Euganean hills, about four miles south-west of that of Monte Rosso. The systematical mineralogists have, generally, assigned the same common origin to most lapideous solids, which they suppose to be generated by deposition from an aqueous fluid; but the structure and other phenomena of these basaltine columns prove them to be crystallizations or concretions of a particular kind, and generated immediately from an igneous fluid; and to be the effects of some intrinsic principle of organization, as Mr. Strange imagines, by which they appear to have been produced simultaneously, in a manner, upon the consolidation of the whole mass of matter, in which they lie, and with which they constantly bear the greatest analogy; and he supposes, that these regular bodies have been generated locally, and not in the midst of those violent convulsions of nature, which are commonly assigned for the origin of volcanic mountains in general. Phil. Trans. vol. lxx. part i. art. 2. p. 5, &c. Vol. lxx. part ii. art. 41. p. 418, &c. See Basaltes.

GIAR *Alkohol*, in *Botany*, a name given by Avicenna, Serapion, and the rest of the Arabian writers, to the potamogeiton of those times. This is translated by some the water-rush, but that is founded on an error; it is certain that the plant thus called by the Arabians, was very different from the potamogeiton of our times. Avicenna

tells us, it had flowers resembling those of the water-lily; and it seems either to have been the sagitta aquatica, or water arrow-head, or else the butomus, or some of the smaller species of nymphæa.

GIAROLA, in *Ornithology*, the name of a bird of the lark kind, remarkable for its very long heel. It is of the size of the common lark. Its head, neck, back, and wings, are of a mottled colour, resembling that of the quail. The general colour of the feathers is a chesnut brown, and their edges are variegated with white, yellow, and red; the back part of its head has a sort of crown or ring of white feathers; its belly is white; its tail is so short that it seems to have none; it is bifid, however, and is elegantly variegated with chesnut-colour and white. Aldrovand. de Avibus, lib. xvii. cap. 39.

GIAROLO, in *Ornithology*, a name by which a small bird of the snipe kind, remarkable for its white tail, is known in the markets of Italy. It very much resembles the bird we call in English the STINT, but its beak is broad at the base, and tapers to a point, and its legs are thicker and shorter. It is not known among authors by any Latin name, except that Aldrovandus has called it the CINCLUS *terrinus*, and cinclus is a very indeterminate name, being applied by different authors to several different birds.

GIB, in *Mechanics*. See CRANE.

GIBBOUS, in *Surgery*, is used to denote a person bunched or bump-backed.

GIBBOSITY is a preternatural incurvation of the spina dorsi either backward, or on one side. Infants are more subject to this disorder than adults, and it often proceeds from external than from internal causes. A fall, blow, or the like violence, frequently thus distorts the tender bones of infants. When it proceeds from an internal cause, it is generally from a relaxation of the ligaments that sustain the spine, or a caries of its vertebræ; though the spine may be inflected forward, and the back thrown out, by a too strong and repeated action of the abdominal muscles; and this, if not timely redressed, usually grows up, and fixes, as the bones harden, till in adults it is totally irretrievable: but when the disorder is recent, and the person young, there are some hopes of a cure. The common method is by a machine of pasteboard, wood, or steel, which is made to press principally upon the *gibbous* part, and this, by long wearing, may set all right. The surgeons, however, have a different instrument, which they call a cross, much more efficacious, though not quite so convenient in the wearing; by the use of this, the parts are always prevented from growing any worse, and are often cured. During the application of these assistances, the parts should be at times rubbed with Hungary-water, spirit of lavender, and the like, and defended with a strengthening plaster of oxycroceum, opodeldoc, or the like. Heister's Surg. part ii. p. 21.

That part of the liver, out of which the vena cava arises, is also called the *gibbous* part.

GIBBOUS is also used in reference to the enlightened parts of the moon, while she is moving from full to the first quarter, and from the last quarter to full again; for all that time the dark part appears horned, or falcated, and the light one bunched out, convex, or *gibbous*.

GIBBOUS *fish*, *gibbosi pisces*, in *Ichthyology*, a name given by Mr. Ray to the fish called by the Dutch *bramingo*. It is a smooth fish without scales; its belly is white; its fins and tail black. It grows to a considerable size, sometimes to four feet. It is caught all over the East Indies, near the sea shores, and is very firm, and much esteemed at table. It has its name from the remarkable rising of its back, which is like that of the pearch, but much higher. Ray's Ichthyology. Append. p. 4.

GIBELINS, GIBELLINI, GIBELLINO, or GHIBELINS, a famous faction in Italy, opposite to another called the Guelphs.

The Guelphs and *Gibelins* ravaged and laid waste Italy for a long series of years: so that the history of that country, for the space of three centuries, is only a detail of their mutual violences and mortal wars.

The Guelphs strenuously asserting the power of the see of Rome, as the *Gibelins* did the emperor's right of sovereignty.

We have but a very obscure account of their origin, and the reason of their names: the generality of authors affirm, that they rose about the year 1240, upon the emperor Frederic the II's being excommunicated by pope Gregory IX.

That prince, say they, making a tour among the cities of Italy, gave the name of *Gibelins* to such as he found well affected to him; and that of Guelphs to those who adhered to the pope. But as to the reason and signification of these words, there is a deep silence; *Gibelin* might possibly be formed of *gibeter*, *imperator*; whence *gibelin-ski*, *imperiales*. Of *gibeter*, the Italians might make by corruption, *Gibelin*; so that *Gibelins*, in that light, should be the same with *Imperialists*, or such as followed the emperor's party.

By the way, some writers maintain, that the two factions arose ten years before; though still under the same pope and emperor.

Other historians relate that Conrad III. marching into Italy, in the year 1130, against the Neapolitans, Roger, count of Naples and Sicily, in order to defend his states, called to his assistance Guelph, duke of Bavaria: and one day, when the two armies were ready to join in battle, the Bavarians cried out in high Dutch, *hie, Guelph!* or, as others say, in Flemish, *hier, Guelph!* that is *here, Guelph!* and that the Imperialists answered on their side, with the words *hie*, or *hier, Gibelin! here, Gibelin!* calling the emperor by the name of the place where he had been bred.

Hornius refers the names to the war in 1140, between Henry the Proud, duke of Bavaria and Saxony, and Conrad III. duke of Suabia; the two princes preparing to engage near the town of Wittberg, the Bavarians began to cry out *Guelph*, which was the name of duke Henry's brother; and the partizans of the emperor *Weibelingen*, which was the name of the place where that prince was born and bred, in the duchy of Wirtemberg, whose surname he bore: from which *Weibelingen* the Italians at length formed *Gibelin*.

This account is confirmed by Martin Cruſius: *Initium Gibelinæ (Wiblingæ à patria Conradi regis) & Welficæ concertationis.* Conrad being of Weibelingen, that word, says Cruſius, gave rise to *gibellingæ*, and that to *gibelinæ*, *Gibelini*, *Gibellini*.

Platina, on the other hand, aſſures us, that the name *Gibelins* arose from that of a German at Piſtoya; whose brother, named Guelph, gave likewiſe his name to the oppoſite faction: the two brethren, it ſeems, bearing an irreconcileable hatred. Others maintain, that the emperor gave the appellation *Gibelins* to thoſe of his party, from the German word *giepffel*, ſignifying *ridge*, or *top*; becauſe the empire reſted on them, as the rafters of a houſe lean on the ridge, which joins them a-top.

Karus, a learned canon of Straſbourg, in the lives of the emperors of the houſe of Brunſwick, is of the ſecond opinion above related: in a battle, ſays he, between Welf, or Guelf, and Frederic, the army of the firſt crying out, *hie, Welf! hie, Welf!* the ſecond commanded his to cry out, *hie, Gibeling! hie, Gibeling!* the name of his birth-place; and the French and Lombards aſking the ſignification of thoſe words, they were anſwered, that by *Welf* was meant the pope's party; and, by *Gibelin*, the emperor's.

Yet others contend, that the word *Gibelin* is only a ſoftening of the word *gibertin*, or *gubertin*; and that it aroſe from Guipert, an antipope, ſet up by the emperor Henry III. in the year 1080.

Among many other conjectures, Maimbourg, in his Hiſt. de la Decad. de l'Emp. advances another opinion, that the two factions, and their names, aroſe from a quarrel between two very ancient and illuſtrious houſes on the confines of Germany, that of the Henrys of *Gibeling*, and that of the Guelphs of Adorf. See Machiavel.

It is ſaid by ſome, that the *Gibelins*, when driven out of Italy, long after the year 1229, at which period the conteſt between them and the Guelphs ran very high, and ſettled at Amſterdam, were the inventors of the mercantile practice of re-change, or re-exchange, on bills of exchange, on account of the damages and charges they were put to, and the intereſt of the money of their bills proteſted, which had been given to them for the effects they had been obliged to leave behind them. Anderſon's Hiſt. Commerce, vol. i. p. 110.

GIBET, or GIBBET, a machine in manner of a gallows, whereon notorious criminals, after execution, are hung in irons, or chains: as ſpectacles, in terrorem.

The word in French, *gibet*, properly denotes what we call *gallows*: it is ſuppoſed to come originally from the Arabic *gibel*, *mount*, *elevation of ground*; by reaſon *gibets* are uſually placed on hills, or eminences.

GIBLETS, the offals, or entrails of a goose; including the heart and liver, with the feet, gizzard, &c.

The word is ſuppoſed to be formed of *goblets*, from the French *gobeau*, *mouthful*.

Giblets make a conſiderable article in cookery: they boil *giblets*, ſtew *giblets*, make ragous of *giblets*, *giblet*-pies, &c.

GIBUR, a general name given by ſome chemical writers, to all medicines drawn by their art from metallic or mineral ſubſtances.

GIDDINESS, the popular name for the diſtemper called by phyſicians VERTIGO.

Giddineſs in horſes is cured by a glyſter and blood-letting,

to be repeated after two days moderate exercise. Dict. Rust. in voc.

GIFT MEHL, the name given by the German chemists and metallurgists, to the first appearance of arsenic, or the grey flowers arising from the roasting of cobalt, and sticking to the long wooden funnel, which they carry from the furnaces. The grey colour of these flowers is occasioned by the smoak of the fuel; and when they are afterwards sublimed in a close vessel, the arsenical flowers begin to grow clammy in that part of the vessel which is last made hot by the continuation of the fire, and there form themselves into a ponderous thick sublimate.

Nevertheless, this sublimate neither runs out, nor gets to the bottom of the vessel when the fire is increased. A tenacious doughy clamminess is indeed communicated to arsenic by the fire; but the fire alone cannot make it melt, but resolves it into a smoak, which, when it can find no way to escape, often bursts the vessels in which it is confined. The yellow arsenic, which has one tenth part sulphur, is by that mixture much more easily formed into a solid sublimate than the white arsenic alone; but the red arsenic, which contains double that quantity of sulphur, cannot easily be formed into a sublimation by ascent, because of its extreme readiness to fuse. The best way of preparing this is therefore to *raise* it out of a retort in the large and long neck of which it may be condensed, and thence fall while yet fluid into the receiver.

Arsenic of this kind may be immediately produced out of some species of pyrites, without any previous addition; or by mixing a sulphureous pyrites of the common kind with one of the white ones, or with any other ore of arsenic; and by this process there will be separated an arsenic, either yellow or red, according to the smaller or larger proportion of the sulphur in the mixture of the whole.

The word *gift mehl*, is German, and signifies poisonous meal or flour.

GIFT, *donum*, in *Law*, is a conveyance which passeth either lands or goods, and is of a larger extent than a grant, being applied to things moveable and immoveable; yet as to things immoveable, when taken strictly, it is applicable only to lands and tenements given in tail; but *gift* and GRANT are often confounded. See DONATION.

A *gift* may be by deed, by word, or in law: thus all a person's goods and chattels, except in some special cases, may be given without deed; though such a gift is liable to suspicion. When such a *gift* is made in satisfaction of a debt, it should be done before witnesses of credit; the goods and chattels should be, at the same time, appraised to the full value; and the *gift* be expressly made in full satisfaction of the debt. As to *gifts* in law; if a man be married, all the goods and chattels of his wife belong to the husband: also, if a person be made EXECUTOR of a will, by *gift* in law, all the testator's goods are his, after paying the testator's debts. And as to deed of *gift*, all things that lie in livery, as messuages, lands, woods, &c. may be given or granted in fee, for life or years, at first; and be assigned over for ever, afterwards. Such a deed may be made upon condition; and if it be of goods and chattels, the delivery of a sixpence is a good seisin of the whole.

GIG-*fish*. See FISH-*gig*.

GIGANTIC. See GIANT.

GIGANTOMACHIA, the battle of the giants against the fabulous gods of the ancient heathens.

The word is Greek, γιγαντομαχια, formed of γιγας, γιγαντος, *giant*; and μαχη, *combat*, of μαχομαι, μαχω, *I fight*.

Several of the poets have composed *gigantomachias*: that of Scarron is the finest of all his pieces.

GIGAROS, in *Botany*, a name given by some writers to the dracontium.

GIGARTON, the stone or kernel of a grape or raisin. Ægineta observes, that grape-stones are drying and refrigerating; and the stones of raisins, on analysis, afford an acid spirit, and empyreumatic oil, and, as some say, a very considerable quantity of a volatile salt.

GIGERIÆ, a term used by some writers, to express the offals of poultry of any kind, including the intestines, extremities, and whatever else is thrown away before the dressing. See GIBLETS.

GIGG, GIGA, or JIG, in *Music* and *Dancing*, a gay, brisk, sprightly composition, and yet in full measure, as well as the allemand, which is more serious.

Menage takes the word to arise from the Italian *giga*, a musical instrument mentioned by Dante.

Others suppose it to be derived from the Teutonic *gieg*, or *ghighe*, *a fiddle*. This is a favourite air in most nations of Europe: its characteristic is duple time, marked $\frac{2}{4}$, or $\frac{6}{8}$: it consists of two strains, without any determinate number of bars.

GIGOT, among *Farriers*, small bladders, or blisters, on the inside of a horse's lips. They must be laid open, and cleansed with salt and vinegar, or alum-water.

GIGGE, in the *Manufacture of Flax*, denotes a hole made in the earth, where fire is made to dry the flax laid over it.

GIGMILLS, a kind of fulling mills, for fulling and burling of woollen cloth, prohibited anno 5 and 6 Edw. VI. c. 22.

GIGOT, in the *Manege*, a branch after the form of a *gigot*, or leg, is a BRANCH, the lower part of which is round, and called in French *gargouille*.

GILAM-HIO, in the *Materia Medica*, a name used by some authors for a peculiar sort of the lignum-aloes, which is soft, whitish, and very sweet-scented.

GILARUM, in *Botany*, a name used by Marcellus, for the SERPYLLUM.

GILBERTINES, an order of religious, thus called from St. Gilbert, of Sempringham, in the county of Lincoln, who founded the same about the year 1148: the monks of which observed the rule of St Augustine; and were accounted canons; and the nuns that of St. Benedict.

The founder of this order erected a double monastery, or rather two different ones, contiguous to each other, the one for men, the other for women, but parted by a very high wall.

St. Gilbert himself founded thirteen monasteries of this order, viz. four for men alone, and nine for men and women together, which had in them seven hundred brethren, and fifteen hundred sisters. At the dissolution there were about twenty-five houses of this order in England and Wales.

GILD, or GUILD, originally signifies a fraternity or company.

The word is formed from the Saxon *gildan*, *to pay*, because every man was *gildare*, *i.e.* to pay something towards the charge and support of the company. Hence also our Guildhall, q.d. the hall of the society or fraternity, where they meet, and make orders and laws among themselves.

The original of *gilds*, or *guilds*, is thus related: it being a law among the Saxons, that every freeman of fourteen years old should find sureties to keep the peace, or be committed; certain neighbours, consisting of ten families, entered into an association, and became bound for each other, either to produce him who committed an offence, or to make satisfaction to the injured party: that they might the better do this, they raised a sum of money among themselves, which they put into a common stock; and when one of their pledges had committed an offence, and had fled, then the other nine made satisfaction out of this stock, by payment of money, according to the offence.

Because this association consisted of ten families, it was called a *decemvary*: and from hence came our later kinds of fraternities.

But, as to the precise time when these *guilds* had their origin in England, there is nothing of certainty to be found; since they were in use long before any formal licence was granted to them for such meetings.

It seems to have been about the close of the eleventh century, says Anderson, in his History of Commerce, vol. I. p. 76, that merchant-*guilds*, or fraternities which were afterwards styled corporations, came first into general use in many parts of Europe. Mr. Madox, in his Firma Burgi, chap. i. § 9. thinks, they were hardly known to our Saxon progenitors, and that they might be probably brought into England by the Normans; although they do not seem to have been very numerous in those days. The French and Normans might probably borrow them from the free cities of Italy, where trade and manufactures were much earlier propagated, and where possibly such communities were first in use. See CITY.

Edward the Third, in the fourteenth year of his reign, granted licence to the men of Coventry, to erect a merchant's *gild* and fraternity of brethren and sisters, with a master, or warden; and that they might found chantries, bestow alms, do other works of piety, and constitute ordinances touching the same.

So Henry the Fourth, in his reign, granted a licence to found a *gild* of the Holy Cross, at Stratford upon Avon.

GILD, in the royal boroughs of Scotland, is still used for a company of merchants, who are freemen of the borough.

Every royal borough has a dean of *gild*, who is the next magistrate below the bailiff. He judges of controversies among men concerning trade; disputes between inhabitants touching buildings, lights, watercourses, and other nuisances; calls courts, at which his brethren of the *gild* are bound to attend; manages the common stock of the *gild*; and amerces, and collects fines.

GILD, or GELD, according to Camden, alſo ſignifies a tribute, or tax. See GELD.

GILD, according to Crompton, alſo ſignifies an amerciament. As in ſoce-*geld*, which he interprets a preſtation within the foreſt.

Hence, to be quit of all manner of *gild*, is to be diſcharged from all manner of preſtations to be made for gathering ſticaves of corn, lamb, and wool, to the uſe of foreſters.

GILD, or GELD, is alſo uſed among our ancient writers for a compenſation, or mulct, for a fault committed. See UNGELD.

Hence, *weregeld* is the price of a man; *orfgeld* is the price of cattle; *angeld*, the ſingle value of a thing; *twigeld*, the double value, &c.

There are divers other words which end with *geld*, and ſhew the ſeveral kinds of payments; as *danegeld*, *tradegeld*, *ſenegeld*, *hengeld*, *ſcotgeld*, *pengeld*, &c. which ſee.

GILD, or GUILD *rents*, are rents payable to the crown by any *gild* or fraternity; or ſuch rents as formerly belonged to religious *gilds*, and came to the crown at the general diſſolution: being ordered for ſale by the ſtat. 22 Car. II.

GILDABLE, or GELDABLE, denotes a perſon tributary, that is, liable to pay tax, or tribute.

Camden, dividing Suffolk into three parts, calls the firſt *geldable*, becauſe liable to tax; from which the two other parts were exempt, becauſe eccleſiæ domitæ.

GILDABLE is alſo explained in an ancient MS. to be that land or lordſhip which is *ſub ſoſtrittione curiæ vicecom.*

GILDER. See GUILDER.

GILDHALDA *Teutonicorum* was uſed for the fraternity of Eaſterling merchants in London; called alſo the STILLYARD.

GILD-HALL, q. d. *Gildæ aula*, the chief hall in the city of London. See GUILD-*hall*.

GILD-MERCHANT, *gilda mercatoria*, was a certain privilege, or liberty, granted to merchants, whereby they were enabled, among other things, to hold certain pleas of land within their own precincts.

King John granted *gildam mercatoriam* to the burgeſſes of Nottingham.

GILDING, or GUILDING, the art, or act, of ſpreading or covering certain ſubſtances with gold, either in leaf, or in amalgam with quickſilver.

The art of *gilding* was not unknown among the ancients, though it never arrived among them at the perfection to which the moderns have carried it.

Pliny aſſures us, that the firſt *gilding* ſeen at Rome, was after the deſtruction of Carthage, under the cenſorſhip of Lucius Mummius, when they began to *gild* the ceilings of their temples and palaces; the Capitol being the firſt place on which this enrichment was beſtowed: But he adds, that luxury advanced on them ſo haſtily, that in a little time you might ſee all, even private and poor perſons, *gild* the very walls, vaults, &c. of their houſes.

We need not doubt but that they had the ſame method with us, of beating gold, and reducing it into leaves; though, it ſhould ſeem, they did not carry it to the ſame height; if it be true, which Pliny relates, that they only made ſeven hundred and fifty leaves, four fingers ſquare, of a whole ounce. Indeed he adds, that they could make more; that the thickeſt were called *bractææ Praeneſtinæ*, on account of a ſtatue of the goddeſs Fortune at Praneſte, gilt with ſuch leaves; and that the thinner ſort were called *bractææ quæſtoriæ*.

The modern gilders alſo make uſe of gold leaves of divers thickneſſes: but there are ſome ſo fine, that a thouſand do not weigh above four or five drachms. The thickeſt leaves are uſed for *gilding* on iron, and other metals: and the thinneſt on wood. But we have another advantage above the ancients, in the manner of uſing and applying the gold: the ſecret of painting in oil, diſcovered of late ages, furniſhes us with means of *gilding* works that ſhall endure all the injuries of time and weather, which to the ancients was impracticable. They had no way to lay the gold on bodies that would not endure the fire but with whites of eggs, or ſize; neither of which will endure the water: ſo that they could only *gild* ſuch places as were ſheltered from the moiſture of the weather.

The Greeks called the compoſition on which they applied their *gilding* on wood, *leucophæum*, or *leucophorum*; which is deſcribed as a ſort of glutinous compound earth, ſerving, in all probability, to make the gold ſtick, and bear poliſhing. But the particulars of this earth, its colour, ingredients, &c. the antiquaries and naturaliſts are not agreed upon.

There are ſeveral methods of *gilding* in uſe among us; viz. *gilding on an oily ſize*; *gilding on a water ſize*; *gilding by the fire*, which is peculiar to metals; *gilding of books*, &c.

Method of GILDING *in oil, or an oily ſize.* The baſis or matter whereon the gold is applied, in this method, according to M. Felibien, is the remains of colours found ſettled to the bottom of the pots wherein the painters wuſh their pencils. This matter, which is very viſcid, they firſt grind; then paſs it through a linen cloth; and thus lay it with a pencil on the matter to be gilt, after having firſt waſhed it once or twice over with ſize; and, if it be wood, with ſome white paſte.

But however this method may obtain in France, the Engliſh *gilders*, in lieu hereof, generally make uſe of a gold ſize, made of yellow oker, ground fine with water, and laid to dry, on a chalk-ſtone; and then ground up with a due proportion of ſat drying oil, to give it the body or degree of ſtiffneſs required.

Linſeed oil may be prepared for this purpoſe, by putting ſuch a quantity of it into a broad veſſel as may cover the bottom about an inch deep, and adding to it as much water as will riſe ſix inches or more above the bottom. Let the veſſel be expoſed to the ſun and rain, and the contents be occaſionally ſtirred for five or ſix weeks, till the oil appear of the conſiſtence of treacle. Then ſeparate the oil from the water, and place it in a long bottle or ſeparating funnel uſed by the chemiſts, in ſuch heat as will render it perfectly fluid; pour off the clear part, and ſtrain the remainder through a funnel, and the whole will be fit for uſe. The water helps to clear and bleach the oil, and improve it in other reſpects.

If the piece to be *gilded* has not already had a coat of oil paint, prime it with the above compoſition, to which a ſmall portion of vermilion may be added. When the priming is dry, the next operation is ſizing the work; which may be done by laying the above ſize on the fat oil, mixed with the *japanner's* GOLD-*ſize*, thinly over the work to be gilt, by means of a brush, or a large pencil: but care ſhould be taken that the brush or pencil be made to paſs into all the cavities and projecting parts, if the ſubject be carved. When great perfection is required, the work ſhould be ſized a ſecond time, and ſome add a third ſizing.

When the work is almoſt dry, but while yet unctuous enough to catch and retain the gold, the workmen ſpread their gold leaves thereon, either whole or cut in pieces.

To take up and apply the leaves, they make uſe of a piece of fine, ſoft, well-carded cotton; or of a pallet for the purpoſe, or barely the knife, wherewith the leaves were cut, according to the parts of the work they are to *gild*, or the breadth of the gold to be applied.

In proportion as the gold is laid, they preſs it down ſmooth with a bunch of cotton, a hare's foot, or ſquirrel's tail, to make it ſtick, and, as it were, incorporate with the ground: and with the ſame hare's foot, or a camel's hair pencil, they mend any cracks that may happen therein, after the ſame manner as will be hereafter ſhewn in *Water*-GILDING.

The ſquirrel's tail uſed in *gilding* is cut ſhort, and ſometimes ſpread in the fan-faſhion, by means of a piece of wood formed like a pencil-ſtick, but broad at both ends, and ſplit to receive the tail; but it will equally ſerve in its own form, when the hair is cut to a proper length. The cotton alſo ſhould be formed into a ball, by tying it up in a piece of fine linen rag; for if it be uſed without the rag, the fibres adhere to the gold ſize, and embarraſs the work. Small pieces of the gold leaf may be applied to thoſe parts of the work, which the ſquirrel's tail and cotton cannot reach, by the point of a ſtich pencil, firſt breathed upon, and thus conveyed to their proper place. When the whole of the work is covered and dry, it may be bruſhed over with a camel's hair pencil, or ſoft hog's-hair bruſh, to take off from it all looſe parts of the gold.

This ſort of *gilding* is chiefly uſed for domes, and the roofs of churches, courts, banqueting-houſes, &c. and for figures of plaſter, lead, &c. that are to ſtand expoſed to the weather.

Method of GILDING *on a water ſize.* Water *gilding*, or burniſh *gilding*, is not performed without more apparatus; nor is it uſed ſo frequently, nor on ſuch large works as the former: wooden works, and thoſe of ſtucco, are almoſt the only ones gilt in this way; which, beſides, muſt be ſheltered from the weather. The ſize made uſe of for *gilding*, is to be made of ſhreds, &c. of parchment, or gloves, boiled in water, in the proportion of about a pound of the ſhreds to ſix quarts of water, to the conſiſtence of a jelly, and then ſtrained through flannel while hot.

If it be wood that is to be *gilt*, thoſe parts that admit of it being firſt well rubbed with fiſh-ſkin, and then with Dutch ruſhes, it is primed with the above ſize, mixed with as much whiting as will give it a tolerable body of colour; and this mixture is made by melting the ſize,

and ſtrewing the powdered whiting into it gradually, and well ſtirring them together. For this whiting, ſome uſe plaſter of Paris, well beaten and ſifted; others Spaniſh white, or ceruſs, &c. It is laid on with a ſtiff brush, and oftener or ſeldomer repeated, according to the nature of the work: for pieces of ſculpture, ſeven or eight lays ſuffice; for flat, or ſmooth works, they uſe ten or twelve. In the latter case they are applied by drawing the bruſh or pencil over the work: in the former, by dabbing it ſmartly on, that the fize may enter all the deeps of the carving.

After the laſt coat is laid on, and before it be quite dry, a bruſh pencil, dipped in water, ſhould be paſſed over the whole, to ſmooth it, and take away any inequalities that may have been formed; and when it is dry, the parts that admit of it ſhould be again bruſhed over till they are perfectly even. The work ſhould then be repaired, by freeing all the cavities from the priming; after which a water poliſh ſhould be given to the parts deſigned to be burniſhed, by rubbing them gently with a fine linen rag, moiſtened with water.

The white thus finiſhed, they proceed to yellow it, obſerving, that, if it be a piece of ſculpture in relievo, they always firſt touch up and repair the ſeveral parts, which the white ground may have diſfigured, with little iron inſtruments, as gravers, chiſſels, gouges, &c.

The yellow which they uſe is only common oker, well ground and ſifted, and thus mixed up with the fize uſed for the white, only weaker by one half. This colour is laid on hot, and, in works of ſculpture, it ſerves to ſupply the place of gold, which frequently cannot be carried into all the cavities and dentings of foliages and other ornaments.

Over this yellow, which is now often omitted, is applied a lay, which is to ſerve for the ground whereon the gold is to be immediately laid; for the preparation of which, ſee GOLD-*ſize*. The ingredients being all ground together with warm fize, mixed with two thirds of water, they apply two or three lays of the compoſition upon the yellow, each after the other is dried, taking care not to put any in the ſmall cavities of the work, to hide the yellow. Some add a little vermilion to the *gilding ſize*. The bruſh uſed in this application is to be ſoft; and when the matter is well dried, they go over it with a ſtronger bruſh or ſoft cloth, to rub it down, and take off the little prominent grains, and thus facilitate the burniſhing of the gold.

In order to proceed to *gild*, they muſt have three ſorts of pencils; one to wet, another to touch up and amend, and a third to flatten: there is alſo required a cuſhion, to ſpread the gold leaves on when taken out of the book: a knife to cut them; and a *hare's foot*, or ſquirrel's tail, fitted with a handle, or elſe a piece of cotton, to take them up, direct, and apply them.

They begin with the wetting pencils, by which they moiſten the layer laſt laid on with water, that it may the better receive and retain the gold: the leaves are then laid on the cuſhion, and taken up, if whole, with the ſquirrel's tail; if in pieces, with the other inſtrument, or even the knife with which they are cut, and laid and ſpread gently on the parts of the work before moiſtened. When the leaves happen to crack or break in laying on, they make up the breaches with little pieces of leaf taken up on the repairing pencil; and with the ſame pencil, or another ſomewhat bigger, they ſmooth the whole; preſſing the gold into the dents, where it could not ſo well be carried with the ſquirrel's tail.

The work being thus far gilt, when dry, and fit for the purpoſe, which it will uſually be in about twenty-four hours, remains either to be burniſhed, or matted.

To burniſh it, is to ſmooth and poliſh it with a burniſher, which is uſually a dog's or wolf's tooth, or a blood-ſtone, an agat, or a pebble, or ſomething elſe very ſmooth, fitted in a handle for that purpoſe.

To mat, is to give it a right luſtre, in the places not burniſhed, with a pencil dipped in ſize, wherein a little vermilion ſometimes has been mixed. This helps to preſerve it, and prevent its flawing, when handled.

Some recommend for this purpoſe red lead, with a little vermilion ground with the white of an egg; but yellow oker, or Dutch pink, with red lead, would better anſwer the end; or the *terra di Siena*, very ſlightly burnt, or mixed with a little red lead, would have a much better effect, and be more durable than any other mixture ſo near the colour of gold in ſhade. Iinglaſs ſize will likewiſe ſupply the place of the whites of eggs. This operation of matting ſuperſedes the neceſſity of yellowing, which is intended to give the appearance of *gilding* to the deeper and obſcure parts of the carving where the gold cannot, nor is thought neceſſary to be laid on.

The laſt thing is to apply a vernicil, or lacker, in all the little lines and cavities; and to ſtop and amend any little faults with ſhell gold.

The compoſition here called *vernicil*, is made of gum gutta, vermilion, and a little of ſome ruddy brown colour, ground together, with Veniſe varniſh, and oil of turpentine. Some *gilders*, in lieu hereof, content themſelves with fine lacca, or dragon's blood, with gum-water.

Sometimes, inſtead of burniſhing the gold, they burniſh the ground or compoſition laid on laſt before it; and content themſelves afterwards to waſh the part over with ſize. The method is chiefly practiſed for the hands, face, and other nudities in the relievo; which, by this means, do not appear ſo very brilliant as the parts burniſhed; though much more ſo than the parts perfectly flat, or matted.

To *gild* a work, and yet preſerve white grounds, they uſe to apply a layer of Spaniſh white, mixed with a weak iſſin-glaſs, on all the parts of the ground whereon the yellow, or the layer next under the gold, muſt run.

GILDING, *japanners*, is performed by means of gold powder, or imitations of it, cemented to the ground by a kind of gold ſize; for the method of preparing which, ſee GOLD-*ſize*. This kind of *gilding* may be practiſed on almoſt any ſubſtance whatever, whether wood, metal, leather, or paper; nor is there any preparation neceſſary, beſides making the ſurface on which the ſize is to be laid, even and perfectly clean. Then ſpread the japanner's ſize, mixed with a due proportion of oil of turpentine and vermilion, with a bruſh over the work, if the whole ſurface is to be gilt; or draw with it, by means of a pencil, the proper figure deſired, avoiding carefully any other parts: when it is almoſt dry, ſo as to be capable, by its clamminеſs, of receiving the gold, dip a piece of wath-leather, wrapped round the finger, in the gold powder, deſcribed under *ſhell* GOLD, and rub it lightly over the ſized work; or ſpread the powder with a ſoft camel's hair pencil: and with a camel's hair-bruſh clear away the looſe powder, after the gilded ſurface is dry. When leaf-gold is uſed, the method of ſizing muſt be the ſame as for the powders; but great care is neceſſary in laying them on, while the ſize is in a proper ſtate of dryneſs.

There is a *falſe kind of gilding*, in which a colour of gold is given by painting and varniſhes, without employing gold. Thus a very fine golden colour is given to braſs, and to ſilver, by applying on theſe metals a gold-coloured varniſh, which, being tranſparent, ſhews all the brilliancy of the metals underneath. Many ornaments of braſs are varniſhed in this manner, which is called *gold lacquering*, to diſtinguiſh them from thoſe that are really gilt. Silver leaves, thus varniſhed, are put upon leather, which is then called gilt leather; and many picture-frames have no other than this counterfeit *gilding*, which may be diſcovered, by waſhing it with a little rectified ſpirit of wine; for the ſpirit will diſſolve the varniſh, and leave the ſilver leaf of its own whiteneſs. For plain picture frames, thick tin-foil may be uſed inſtead of ſilver; the tin-leaf, fixed on with glue, is to be burniſhed, then poliſhed with emery, and a fine linen cloth, and afterwards with putty, applied in the ſame manner; being then lacquered over with the varniſh five or ſix times, it looks like burniſhed gold. See LACQUERING. Among the *falſe gildings* may alſo be reckoned thoſe which are made with thin leaves of copper or braſs, called Dutch leaf. In this manner are made all the kinds of what is called gilt paper. See GILDING *of paper*.

GILDING *of books*. See BOOK-*gilding*, and GILDING *of paper*.

GILDING *on china-ware*. The gold is very much valued on *china-ware*, and would be much more ſo were it not that it is very liable to loſe its luſtre, and to rub off. The Chineſe, at preſent, have a method of preventing both theſe accidents, in a great meaſure, by means of a ſort of poliſhing, which they give it, after it is laid on. They prepare for this purpoſe, a fine piece of agate, which they poliſh on one ſurface in as perfect a manner as poſſible. With this they rub over the gold as it lies on the porcelain ſeveral times, when it firſt comes from the baking. This gives the gold a luſtre which it would not otherwiſe have, and fixes it down to the ware in ſuch a manner that it cannot eaſily be got off. The principal miſchief that gold, thus laid on, is ſubject to, is the tarniſhing, or growing dull: this is remedied by the ſame ſort of means. They wet the veſſel upon which they would revive the luſtre of the gold, in common clear water; and while it is wet, they rub it with the ſame poliſhed agate, adding a little fair water at times to keep it moiſt. If the gold has not been well laid on at firſt, this may poſſibly raiſe it, or take it off in ſome places; but if it was originally put on with the help of this ſtone, as all the gold on porcelain now is, the rubbing it with it a ſecond time never gives it any ſcratches, but recovers its priſtine luſtre and beauty. It muſt be obſerved that the rubbing with this ſtone muſt be all done one way, both in the firſt laying

on the gold, and in the brightening of it up afterwards. This may ſerve as a method for us as well as the Chineſe, not only to recover the beauty of our tarniſhed gilt *chinaware*, but alſo to lay gold upon ſome of our home manufactures of this kind. Obſerv. ſur les Coutûmes de l'Aſie. See PORCELAIN.

GILDING *on enamel and glaſs* is performed by burning or annealing, i. e. by producing a cohesion of the gold with the glaſs or enamel, by the intermediation of a flux, or by producing the like effect without any. In both theſe methods, the gold is made to adhere to the enamel or glaſs, in conſequence of the fuſion or approach to that ſtate, either of the flux uſed, or of the body of the enamel or glaſs itſelf, by which the gold is cemented to ſuch body. The flux, when any is uſed, may be either ſimple glaſs of borax, or any of the preparations of FLUXES powdered; and the gold is uſed, either in the form of *leaf* GOLD, or in that of powder made mechanically, or by precipitation. See GOLD *powder*. When leaf gold is employed without any flux, the enamel or glaſs may be moiſtened with a very weak ſolution of gum arabic, and again dried. After being thus prepared, it ſhould be breathed upon till it becomes a little adhelive or ſticky, and then laid upon a ſufficient number of leaves of gold; when the gold is thus united to the enamel or glaſs by the cementing quality of the gum arabic, the work is ready for burning. If a flux be uſed, it ſhould be finely levigated, tempered with a very weak ſolution of gum arabic, and very thinly ſpread on the part of the work to be gilded; and when the gum water is almoſt dry, the leaf gold ſhould be laid on the part thus prepared for it, which is then in a ſtate proper for burning. In the preſent practice, the *purum fulminans*, or precipitation of gold by alkaline ſalts, is made by thoſe who gild glaſs in the greateſt perfection; and the volatile alkali is employed for the precipitation by the chemiſt, who prepares it for this purpoſe. But when this kind of precipitate is choſen, the uſe of any flux muſt be avoided, and a very conſiderable degree of heat applied. The manner of uſing the precipitate powders of gold, the *purum fulminans* excepted, as well as the leaf gold, may be varied, by adding to it or omitting any flux; but in what way ſoever the powder is uſed, it is to be tempered with the oil of ſpike, and worked as the ENAMEL colours; and the quantity of flux, when any is uſed, may be a third of the weight of the gold. In caſes where the glaſs is very hard, or where the opportunity of a ſtrong heat cannot be conveniently obtained, the expedient of uſing a flux in the following manner may be adopted with great advantage. Grind glaſs of borax to a fine powder; and, having tempered it with oil of ſpike, lay it on the glaſs where the *gilding* is to be made; then burn the glaſs with a degree of heat, that will cauſe the borax to run; and when it is cold, apply the precipitate or leaf gold, and burn it again, as in other caſes. After the work is burnt, if it be intended to be burniſhed, a proper luſtre may be given to it, by rubbing the gilded part with a dog's tooth, or with a fine agate, or ſtone burniſhers. Handmaid to the Arts, vol. i. p. 374, &c. See *Ruby* GLASS.

Drinking glaſſes, with gilt edges, have been much admired in this country; the beſt of theſe are brought from Germany; thoſe that are made in England, though equal in beauty to the foreign, being greatly inferior in the durability of the *gilding*. Dr. Lewis made ſeveral experiments with a view of diſcovering this art; from which he concludes, that the gold is cemented to them by means of an intervening matter, which will adhere to glaſs ſo as not eaſily to be rubbed off. He tried maſtich, and other reſinous bodies rubbed warm on the glaſs, and ſeveral ſpirituous varniſhes; but none of theſe were found to adhere ſufficiently to the glaſs. He recommends to the trial of the artiſts in this way the hardeſt oil varniſhes; and glaſſes have been ſince prepared in England, probably on the principles which he has pointed out, with as durable *gilding* as thoſe brought from Bohemia and Thuringia.

M. Zeigler, in a German tranſlation of the Commercium Philoſophico-Technicum, deſcribes a varniſh for this purpoſe, with the method of uſing it, which appeared from his experiments to be the beſt. This varniſh is prepared by boiling fine tranſparent amber, reduced to powder, in a braſs veſſel, to the cover of which a valve is fitted, with as much drying oil as will juſt cover it; and by diluting the above ſolution with four or five times its quantity of oil of turpentine. This varniſh may be made to dry ſooner, and acquires greater firmneſs by grinding in with it a little white lead, or rather with a mixture of white lead and minium. It is to be applied very thin on the glaſs, and the gold leaf laid lightly on the varniſhed part; when the varniſh is thoroughly hardened, the gold may be burniſhed, by laying a piece of ſmooth paper between the tooth or ſteel burniſher, and the gold. This *gilding*, M. Zeigler obſerves, is durable, and of a fine luſtre. Com. Phil. Techn. p. 65, and 614.

GILDING *of figures and letters on paper*, and for the embelliſhments of manuſcripts, is performed with *ſhell*-GOLD, tempered with gum-water; or the characters may be drawn with a milky ſolution of gum ammoniacum made in water, and gold-leaf applied upon them when almoſt dry; or if all or any part of them is become quite dry, they may be again ſufficiently moiſtened for receiving the gold by breathing on them. Letters raiſed from the ſurface of paper or parchment, in the manner of embolſed work, ſuch as are ſeen on ancient manuſcripts, may be formed either by friction on a proper body with a ſolid piece of gold, or by leaf gold. The former method is practiſed by tempering pulverized cryſtal with ſtrong gum water, and with this paſte forming the letters; when they are dry, they are rubbed with a piece of ſolid gold, as in poliſhing, and the letters will appear as if gilt with burniſhed gold. The letters are formed with an embolſed figure, either of the ſeparate letters, or of whole words, cut in ſteel; and each letter of theſe ſtamps, when they are uſed, is anointed evenly with a feather dipt in oil. Then fill theſe concave letters with the above paſte, and ſtrike the ſtamps in a perpendicular direction on the paper or vellum, laid over ſome ſheets of paper.

When the embolſed letters are formed with leaf gold, the following, or a ſimilar compoſition, muſt be uſed. Thicken beaten whites of eggs with as much vermilion as is neceſſary to give them the conſiſtence of paſte; uſe the ſtamps as before; and when the letters are dry, moiſten them by a ſmall pencil with ſtrong gum water, and when this is almoſt dry, cover the letters with leaf-gold, preſſing it cloſe to every part of them with cotton or ſoft leather; after the *gilding* is dry, poliſh it with proper burniſhers. Com. Phil. Techn. p. 64, and Handmaid to the Arts, p. 450, &c.

GILDING *of fine fiſh*, as craw-fiſh, carps, &c. may be performed without injuring the fiſh, by means of a cement, which Mr. Hooke, in his poſthumous papers, directs to be prepared in the following manner: put ſome Burgundy pitch into a new earthen pot, and warm the veſſel till it receives ſo much of the pitch as will ſtick round it; then ſtrew ſome finely powdered amber over the pitch when growing cold; add a mixture of three pounds of linſeed oil, and one of oil of turpentine; cover the veſſel, and boil the contained ingredients over a gentle fire; grind the mixture as it is wanted, with ſo much pumice-ſtone in fine powder as will reduce it to the conſiſtence of paint. When the fiſh has been wiped dry, this mixture is ſpread upon it, and the gold leaf laid over it, and gently preſſed down: after which, the fiſh may be immediately put into water, and the cement will harden, and be in no danger of falling off.

GILDING *on leather*. See LACQUERING.

GILDING *of metals* may be done by cleaning the ſurface of the metal, and applying gold leaves to it, which, by means of rubbing with a poliſhed blood-ſtone, and a certain degree of heat, are made to adhere perfectly well. In this manner ſilver leaf is fixed and burniſhed upon braſs, in making French plate; and ſometimes alſo gold leaf is burniſhed upon copper and upon iron. Some metals, and particularly ſilver, may be gilt in the following manner: dip pieces of linen in the ſolution of gold by aqua regia, and then burn them to aſhes; rub theſe aſhes on the ſurface of the ſilver, well cleanſed from any uneteuous matter, with a wet linen rag, and the particles of gold contained in them will thus be applied to the ſilver, and adhere to it, without the application of heat, or intervention of any other body. Burniſh the ſilver with a blood-ſtone, till it acquires the colour of gold. Moſt gilt ornaments on fans, ſnuff-boxes, and other toys of much ſhow and little value, are nothing but ſilver gilt in this manner. See *Method of* GILDING *metals by the fire*.

GILDING *on paper, parchment*, and *vellum*. There are various methods uſed for this purpoſe, according to the ſeveral ends which the *gilding* is deſigned to anſwer. But for the moſt part ſize, properly ſo called, and gum water, are uſed as the cements, and the powders are more generally employed than the leaf gold. See the three firſt articles in GILDING.

The *gilding* proper to be uſed with water-colours may be either with the leaf-gold or powder: the leaf-gold may be laid on the deſigned ground by means either of gum water, or iſinglaſs ſize; obſerving, that the gum water or ſize be of the weaker kind, and laid ſparingly on the ground, and at that proper time be allowed for it to be dry; and then the gold is applied to it, as in the articles above recited; and it may be poliſhed, if neceſſary, by the dog's tooth, or other kind of burniſher. In *gilding* larger ſurfaces, it will be found uſeful to colour the ground with the gall-ſtone; and when colours are to be laid on the

gilding, the gall of any beast brushed over the gold will adapt it for receiving the colours. When the gold powders are used along with paintings in water-colours, they are previously formed into *shell*-GOLD. The *gilding* proper for the coloured paper used in binding books, and for other such purposes, is performed much in the same manner; only, that the gum water and size may be much stronger, and that they are generally conveyed to the ground by means of a wooden plate or print, or by an engraved roller, which make an impression of the intended figure or design. In this kind of *gilding*, the japanners gold-size may be also commodiously employed; and this should be always used when the embossed appearance is wanted in the greatest degree; and for this purpose it should be thickened with yellow oker, mixed with as much red lead as the proper working of the print will admit. Instead of the genuine leaf-gold, or gold powder, the German powder, formed of the leaves called Dutch gold, is commonly used in this kind of *gilding*. The edges of books or paper are gilt in the manner directed under the article BOOK-*binding*. The cement to be used for this purpose may be strong gum-water, isinglass size, or glover's size; or isinglass melted, with the addition of some common proof spirit of wine, and a fifth part of honey or sugar-candy, to which should be added a third part of bole armoniac. Or the following composition may be used: mix equal parts of bole armoniac and sugar-candy, well powdered, with the whites of eggs beaten to an oily consistence.

GILDING *on thread and wire*. See GOLD-*thread*, and GOLD-*wire*.

GILDING *on wood*. See the three first articles in GILDING.

Method of GILDING *metals, or of* gilding *by the fire*. There are two ways of *gilding* by fire; viz. that with liquid gold, and that with leaf-gold.

The first is performed with gold amalgamated with mercury, in the proportion of about six or eight parts of mercury to one of gold.

In order to this operation, they heat a crucible red-hot, then put the gold and mercury in it, and stir them gently about, till the gold be found melted and incorporated into a mass with the mercury. See AMALGAMATION *of gold*. They then cleanse it by grinding it in a glass, stone, or wooden mortar, with some common salt and water, and occasionally renewing the water, till the amalgam ceases to discolour it, and appears of a pure vivid brightness. From the mass they separate the mercury not united therewith, by squeezing it between the fingers through a piece of shamoy skin, or a linen cloth. To prepare the matter to receive this amalgam, they scrub it with a wire-brush, and wet it with water or beer; continuing to rub and wet it till all the foulness which might hinder the close union of the metals be removed; which done, to quicken the work farther, they rub a mixture of quick-silver and aqua fortis over it; the aqua fortis serving not only to cleanse the surface of the metal from any rust or tarnish it may have acquired, but also to facilitate the application of the amalgam to its surface, by dissolving part of the mercury of the amalgam; and besides, when this solution is applied to the copper, this latter metal having a stronger disposition to unite with the nitrous acid than the mercury has, precipitates the mercury upon its surface.

They proceed now to apply the amalgam of gold, in order to which they use a little knife, or a brush made of brass wire for the purpose; with which they spread or overlay the whole work, as evenly as may be, being careful to miss no part. Then giving the work a gentle heat before the fire, with the hair-brush they dab and spread the amalgam farther and nearer on it.

Thus far advanced, the metal is set over the fire, upon a grate, or in a sort of cage, under which is a pan of charcoal, yielding a heat just sufficient for evaporating the mercury; by which means the mercury is raised in fumes, and leaves the gold alone adhering to the work: in proportion as the mercury, evaporating and flying off, discovers places where gold is wanting, they take care to supply them, by adding new pieces of amalgam with the knife or brush.

If a thicker *gilding* be required than can result from so much of the amalgam as is applied at once, the metal, after the first quantity has left its gold fixed on the surface, is rubbed afresh with the mixture of mercury and aqua fortis, and more of the amalgam spread upon it.

After the evaporation of the mercury from this, another quantity may be applied in the same manner. When the mercury is evaporated, so that the surface becomes uniformly of a pale yellow colour, the metal is made to undergo other operations, by which its colour and lustre are heightened. For this purpose, it is first rubbed with a scratch brush, composed of fine brass wire, till its surface is made clean and smooth; then it is covered over with a composition called *gilding* wax, and again exposed to the fire till the wax be burnt off; and this application is repeated till the gold appears of a proper colour. This *gilding* wax is composed of bees wax, mixed with some of the following fubftances; viz. red oker, verdegrise, copper scales, alum, vitriol, and borax. Thus the colour of the *gilding* is heightened by a perfect diffipation of some mercury remaining after the former operation. The gilt surface is then covered over with a saline compofition, confisting of equal quantities of nitre, sal armoniac, green vitriol, and verdegrise, finely powdered, and mixed up into a paste with water or urine. The piece of metal thus covered is heated till the mixture smokes, and quenched in water or urine. This effect seems to be produced by the acid of nitre, which is disengaged by the vitriolic acid of the alum, or other vitriolic salt, during the rarefaction to heat, acting upon any particles of copper which may happen to be on the gilded surface. Some artists think they give an additional lustre to their gilt work, by rinsing it in a liquor prepared by boiling some yellow materials, as saffron, orpiment, or turmeric. The only advantage of this operation is, that a part of the yellow matter remains in some of the hollows of the carved work, in which the *gilding* is apt to be more imperfect, and to which it gives a rich and solid appearance.

This method of *gilding* by amalgamation is chiefly used for *gilding* copper, or rather copper mixed with a seventh part of brass, thus forming a composition of copper and zinc; which more readily receives the amalgam, and yields a colour more resembling that of gold than the colour of copper.

Iron cannot be gilt by amalgamation, unless it be previously coated with copper, by dipping it in a solution of blue vitriol, or rubbed with the vitriol itself a little moistened. Iron may also receive a golden coat from a saturated solution of gold in aqua regia, mixed with spirit of wine; because the iron, having a greater affinity with the acid, precipitates the gold from it. But the method commonly used of fixing gold upon iron is that mentioned in the next article.

GILDING *by the fire with gold leaves*. To prepare the metal for this *gilding*, it must be first well scratched, or raked, then polished with a polisher; and then set to the fire to blue, i. e. to heat, till it appear of a blue colour. This done, the first lay of gold is clapped thereon, and lightly rubbed down with a polisher; and thus exposed to a gentle fire.

They usually only give it three such lays, or four at most, each lay consisting of a single leaf for the common works, and of two for the extraordinary ones; after each lay they set it afresh to the fire. After the last lay, the gold is in a condition to be burnished.

Another method is mentioned by authors of *gilding* upon metals, and also upon earthen-ware and glass, which is, to fuse gold with regulus of antimony, to pulverize this mass, and spread the powder upon the piece to be gilt; afterwards to expose it to such a fire that the regulus may be evaporated while the gold remains fixed. Bos Dr. Lewis mentions the following inconveniencies to which this method is subject: the powder does not adhere to the piece, and cannot be equally spread; part of the gold is dissipated along with the regulus; gold is fusible with the heat necessary for the evaporation of regulus of antimony; and copper is liable to be corroded by the regulus, and to have its surface rendered uneven. See Lewis's Com. Phil. Tech. p. 77, &c. p. 82, 87 & 88. 104. Macquer's Dict. Chem. Eng. edit. 1777. art. GILDING.

GILDING-*cushion*. See CUSHION.

GILDING-*knife*, a flip of the hollow agamba cane, cut up to a smooth and sharp edge, with a good pen-knife: this cane knife cuts the gold leaf better than one of steel, as it is apt to stick to this last.

GILDING-*pallet*, a flat piece of wood, about three inches long, and an inch broad, covered with a piece of fine woollen cloth.

By breathing upon this pallet, to moisten the cloth a little, and then clapping it gently down upon the gold leaf, this may be raised from the cushion, and conveyed to the work to be gilded.

GILDING-*size*. See GILDING *of Metals*.

GILEAD, *balm of*. See BALSAM.

GILEAD, *balm of*, *Dracocephalum*, in *Botany*. See DRACOCEPHALUM.

GILGUL *hammethim*, a Hebrew phrase, literally signifying *the rolling of the dead*. To conceive the use of this expression it is to be observed, that the Jews have a tradition that, at the coming of the Meshiah, no Israelite shall rise any-where but in the Holy Land. What, then, shall become of all the faithful interred in other parts? shall they perish, and remain in the state of death?

No.

No, say the Jewish doctors; but God will dig them subterraneous canals, or cavities, through which they shall roll from their tombs to the Holy Land; and, when they are arrived there, God will blow on them, and raise them again.

This imaginary passage of the carcases, or ashes, of the Jews, from their tombs to the Holy Land, by rolling under-ground, is what they call *gilgul hammethim*, the rolling of the dead.

GILL. See GROUND-IVY.

GILLA, in *Chemistry* and *Pharmacy*, is an *Arabic* term for salt, peculiarly used among us for the emetic salt of vitriol.

This salt is prepared from that mineral, by three or four repeated operations; viz. dissolution, in May-dew; filtration, and crystallisation. In defect of May-dew, rain-water may serve.

Gilla is used in tertians, and all fevers arising from a corruption of humours, in the first passages. It destroys worms, and prevents putrefaction. The dose is from twenty grains to half a drachm, taken in broth, or in cordial waters.

GILLAROO, *trout*. See TROUT.

GILLS, *branchiæ*, in *Natural History*, those membranous cartilaginous parts in fishes, whereby they respire.

What we call *gills*, in fishes, serve the purposes of lungs: respiration of air is necessary to fishes as to terrestrial animals: there is always a quantity of air included among water; and it is this air that fishes respire. The whole mechanism of their *gills* is contrived with this view; viz. to separate, and imbibe this air, from the water, and present it to the blood, after the same manner as it is presented to the lungs of other animals. All fish, therefore, have these *gills*, except the cartilaginous and petromyzon.

M. Du Verney has unravelled this infinitely complicated piece of mechanism, in the *gills* of a carp: the first thing that offers is a fabric, consisting of a great number of bony laminæ, each subdivided into an infinity of bony fibres, whose office is, to sustain the innumerable ramifications of an artery dispatched thither from the heart: the use of these ramifications is, to present the blood, extremely subdivided, and, as it were, each globule of blood by itself, to the water. Between these laminæ, and throughout the whole contexture of the *gills*, are an infinite number of very narrow passages, destined to receive and subdivide the water which the fish takes in by the mouth, into little parcels. In this state the air, its prison-doors being now in some measure opened, makes its escape, and joins itself to the blood of all the little arteries.

The *gills* have necessarily an alternate motion of dilatation and compression, which is effected by another very curious piece of mechanism; when they dilate, the water is taken in; and when they contract, it is expelled again. Hence it is probable, that it is in the very instant of contraction, that the air expanded from the water is forced to enter the pores of the little blood-vessels, because the force is then greater than at any other time; and this action requires a considerable force. The same reason holds with respect to the lungs of men: accordingly, M. du Verney maintains, that though the air enter the lungs in the time of inspiration, it is only received into the blood in that of expiration, when the superfluous air is carried off by the trachea; so that the real inspiration, i. e. the entrance of the air into the blood, should be the expiration.

The water is taken in by the mouth, and carried off again, freed of its air, by the *gills*; and the air gained from it, is distributed, first to the arterioles of the *gills*, and thence, by the law of circulation, to all the little veins intercurrent therewith.

The *gills* in all fish are eight in number, four being placed on each side the throat. The lowest *gill* is always much smaller than either of the others; the other three on each side are gradually larger to the upper one, which is in all fish the largest. Every one of these *gills* is composed of a bony substance formed into a semicircle, in small links, or bent into the shape of a bow. On the convex side of which there is formed a sort of plume, or the resemblance of a leaf.

Each leaf (so the small bow is composed of a double row of bony lamellæ, somewhat like to many sickles, and each of these lamellæ is fixed to the convex part of the bow, by means of the membrane with which that bow is covered. These lamellæ have one part convex, and the other concave. The convex side is covered with numerous hairs as all guns, and these are longest near the base, and diminish now and then. They are left hairy on the concave side; the hairs there being shorter, and continued only to the middle of the lamellæ, not running all the way along it. These hairs are all the way connected to the *gill* by a very tender membranous substance which covers the lamellæ, but they are each single at the base. Attedi, Ichthyolog.

The concave part of every lamina is applied to the convex part of the next opposite lamina, and the laminæ are all connected one with another, by means of a membrane which arises at their base, and is continued by half their length; at this part the membrane becomes stronger, and forms a sort of cord. The rest of the lamina is free, and terminates in an extremely fine and flexible point. Every one of these laminæ is invested with a fine and thin membrane, and each serves to receive the ramifications of the vessels which are brought into the branchiæ. The inside of every bow or bony semicircle which makes one *gill*, gives place to one artery, one vein, and one nerve. The conformation of this hollow part of each *gill* is different in different fish; in some it contains a number of smooth tubercles, which are short, and scarce stand out beyond the surface: this is the case in the *gills* of the cyprinus, &c. In some it is in this manner beset with very rough tubercles, as in the cottus; in some others these tubercles are rough, and resemble teeth, as in the labrus, &c. In some also this surface, instead of tubercles, is beset with a sort of long hairs resembling rays as in the clupea and sinuffy, in some this part is beset with real, but short prickles, as in the echeneis. The use of the *gills* in fish seems to be to receive the blood which is protruded from the heart into the aorta, and drive it to the utmost parts of the lamina, from whence it is returned by veins which distribute it to every part of the body, and to serve for the office of respiration. The motion of the *gills* of fish is no way so beautifully seen as in the viewing those of a small eel with a microscope. Two rows of these are always beaded together against the other, while their ends play against one another, touching and going back again very regularly and successively, and imitating the opening and shutting of a pair of bellows, in a regular succession; and, in the generality of fish, one pair does this, while another pair only continues advancing, so as to close with their base, and this is done alternately by one and another pair all the time that the observation is continued. Phil. Trans. N° 225.

GILLS, *apertures of the*. See BRANCHIÆ.

GILLS, *leaf of the*. See FOLIUM *branchiarum*.

GILLY-*flower*, or JULY-*flower*. See PINK.

GILLY-*flowers*, *queen's*. See *Dame's* VIOLET.

GILLY-*flower*, *stock*. See STOCK *Gilly-flower*.

GILT-*head*, *Bartata*, in *Ichthyology*, the name of a broad and flat fish, not unlike the bream in shape. It sometimes grows to eight or ten pounds weight; its scales are moderately large, its back is of a blackish green, and its sides of a dusky brown, with a faint cast of yellow. At the upper angle of the coverings of the *gills* is the usually a black spot, and under that often a purple one between its eyes. It has a fine gold-coloured, arched, or situated mark, the convex or gibbous part of which is toward the mouth, the points toward the eyes; and, therefore, in the Linnæan system, it is the SPARUS *lunula aurea inter oculos*. The dorsal fin extends almost the whole length of the back, and consists of twenty-four rays, the eleven first spiny, the others soft; the pectoral fins consist of seventeen soft rays; the ventral of six rays, the first of which is very strong and spiny; the anal fin of fourteen, the three first spiny; and the tail is much forked. The grinders of this fish are flat and strong, like those of certain quadrupeds; besides which they have certain bones in the lower part of the mouth, which assist in grinding their food.

It is common in the markets of Rome, Venice, &c. and caught in great plenty in the summer months in different parts of the Mediterranean; in winter it is more scarce, but more valued. Some have confounded this fish with the sea-bream of ARABUS *pagrus* of Linnæus. See PAGRUS.

GIMBOLS, denote the brass-rings by which a sea-compass is suspended in its box that usually stands in the GIMBLE.

GIMBLETING, in *Sea-language*, is applied to the anchor, to denote the action of turning it round by the shank, so that the motion of the beck appears similar to that of the handle of a gimblet, when it is employed to turn the wire.

GIMMER-*lamb*, or GAIMER-*lamb*, a term used for the female or ewe lamb.

GIN, in *Artillery* and *Mechanics*, is a machine for raising great weights, composed of three long legs, two of which are kept at a proper distance by means of two iron or wooden bars fixed to one of the legs by means of a bolt at one end, and by the other end to the other leg with a bolt and key, so that it may be put on or off at pleasure. At three feet from the bottom is a roller moving in cheeks, that are fastened to these poles by two iron bands and two iron bolts. The three legs of this machine are joined together

gilding, the gall of any beast brushed over the gold will adapt it for receiving the colours. When the gold powders are used along with paintings in water colours, they are previously formed into *shell*-GOLD. The *gilding* proper for the coloured paper used in binding books, and for other such purposes, is performed much in the same manner; only, that the gum water and size may be much stronger, and that they are generally conveyed to the ground by means of a wooden plate or print, or by an engraved roller, which make an impression of the intended figure or design. In this kind of *gilding*, the japanners gold-size may be also commodiously employed; and this should be always used when the embossed appearance is wanted in the greatest degree; and for this purpose it should be thickened with yellow oker, mixed with as much red lead as the proper working of the print will admit. Instead of the genuine leaf-gold, or gold powder, the German powder, formed of the leaves called Dutch gold, is commonly used in this kind of *gilding*. The edges of books or paper are gilt in the manner described under the article BOOK-*binding*. The cement to be used for this purpose may be strong gum-water, isinglass size, or glover's size; or isinglass melted, with the addition of some common proof spirit of wine, and a fresh part of honey or lump sugar, to which should be added a third part of bole armoniac. Or the following composition may be used: mix equal parts of bole armoniac and sugar-candy, well powdered, with the whites of eggs beaten to an even consistence.

GILDING *on thread and wire*. See GOLD-*thread*, and GOLD-*wire*.

GILDING *on wood*. See the three first articles in GILDING.

Method of GILDING *metals, or of* gilding *by the fire*. There are two ways of *gilding* by fire; viz. that with liquid gold, and that with leaf-*gold*.

The first is performed with gold amalgamated with mercury, in the proportion of about six or eight parts of mercury to one of gold.

In order to this operation, they heat a crucible red-hot, then put the gold and mercury in it, and stir them gently about, till the gold be found melted and incorporated into a mass with the mercury. See AMALGAMATION *of gold*. They then cleanse it by grinding it in a glass, stone, or wooden mortar, with some common salt and water, and occasionally renewing the water, till the amalgam ceases to discolour it, and appears of a pure vivid brightness. From the mass they separate the mercury not united therewith, by squeezing it between the fingers through a piece of shamow skin, or a linen cloth. To prepare the metal to receive this amalgam, they scrub it with a wire-brush, and wet it with water or beer; continuing to rub and wet it till all the foulness which might hinder the close union of the metals be removed; which done, to quicken the work farther, they rub a mixture of quicksilver and aqua fortis over it: the aqua fortis serving not only to cleanse the surface of the metal from any rust or tarnish it may have acquired, but also to facilitate the application of the amalgam to its surface, by dissolving part of the mercury of the amalgam; and besides, when this solution is applied to the copper, this latter metal having a stronger disposition to unite with the nitrous acid than the mercury has, precipitates the mercury upon its surface.

They proceed now to apply the amalgam of gold, in order to which they use a little knife, or a brush made of brass wire for the purpose; with which they spread or smear the whole work, as evenly as may be, being careful to miss no part. Then giving the work a gentle heat before the fire, with the hair-brush they dab and spread the amalgam farther and evener on it.

Thus far advanced, the metal is set over the fire, upon a grate, or in a sort of cage, under which is a pan of charcoal, yielding a heat just sufficient for evaporating the mercury; by which means the mercury is raised in fumes, and leaves the gold alone adhering to the work: in proportion as the mercury, evaporating and flying off, discovers places where gold is wanting, they take care to supply them, by adding new pieces of amalgam with the knife or brush.

If a thicker *gilding* be required than can result from so much of the amalgam as is applied at once, the metal, after the first quantity has left its gold fixed on the surface, is rubbed afresh with the mixture of mercury and aqua fortis, and more of the amalgam spread upon it.

After the evaporation of the mercury from this, another quantity may be applied in the same manner. When the mercury is evaporated, so that the surface becomes uniformly of a pale yellow colour, the metal is made to undergo other operations, by which its colour and lustre are heightened. For this purpose, it is first rubbed with a scratch brush, composed of fine brass wire, till its surface is made clean and smooth; then it is covered over with a composition called *gilders* wax, and again exposed to the fire till the wax be burnt off; and this application is repeated till the gold appears of a proper colour. This *gilding* wax is composed of bees wax, mixed with some of the following substances; viz. red oker, verdegrise, copper scales, alum, vitriol, and borax. Thus the colour of the *gilding* is heightened by a perfect diffusion of some mercury remaining after the former operation. The gilt surface is then covered over with a saline composition, consisting of equal quantities of nitre, sal ammoniac, green vitriol, and verdegrise, finely powdered, and mixed up into a paste with water or urine. The piece of metal thus covered is heated till the mixture smokes, and quenched in water or urine. This effect seems to be produced by the acid of nitre, which is disengaged by the vitriolic acid of the alum, or other vitriolic salt, during the exposure to heat, acting upon any particles of copper which may happen to lie on the gilded surface. Some artists think they give an addition of lustre to their gilt work, by covering it to a proper degree with boiling some yellow materials, as soot, turmeric, orpiment, or turmeric. The only advantage of this operation is, that a part of the yellow matter remains in some of the hollows of the carved work, in which the *gilding* is apt to be more superficial, and to which it gives a rich and solid appearance.

This method of *gilding* by amalgamation is chiefly used for *gilding* copper, or rather copper mixed with a seventh part of brass, thus forming a composition of copper and zinc; which more readily receives the amalgam, and yields a colour more resembling that of gold than the colour of copper.

Iron cannot be gilt by amalgamation, unless it be previously coated with copper, by dipping it in a solution of blue vitriol, or rubbed with the vitriol itself a little moistened. Iron may also receive a golden coat from a saturated solution of gold in aqua regia, mixed with spirit of wine; because the iron, having a greater affinity with the acids, precipitates the gold from it. But the method commonly used of fixing gold upon iron is that mentioned in the next article.

GILDING *by the fire with gold leaves*. To prepare the metal for this *gilding*, it must be first well scratched, or raked, then polished with a polisher; and then set to the fire to blue, i. e. to heat, till it appear of a blue colour. This done, the first lay of gold is clapped thereon, and lightly rubbed down with a polisher; and thus exposed to a gentle fire.

They usually only give it three such lays, or four at most, each lay consisting of a single leaf for the common works, and of two for the extraordinary ones; after each lay they let it stand in the fire. After the last lay, the gold is in a condition to be burnished.

Another method is mentioned by authors of *gilding* upon metal, and also upon earthenware and glass; which is, to fuse gold with regulus of antimony, to pulverize this mass, and spread the powder upon the piece to be gilt; afterwards to expose it to such a fire that the regulus may be evaporated while the gold remains fixed. But Dr. Lewis mentions the following inconveniences to which this method is subject: the powder does not adhere to the piece, and cannot be equally spread; part of the gold is dissipated along with the regulus; gold is fusible with the heat necessary for the evaporation of regulus of antimony; and copper is liable to be corroded by the regulus, and to have its surface rendered uneven. Lewis's Com. Phil. Tech. p. 77, &c. p. 82, 83. and 168. Marquer's Dict. Chem. Eng. edit. 1777. art. GILDING.

GILDING-*cushion*. See CUSHION.

GILDING-*knife*, a flip of the hollow Spanish cane, cut up to a smooth and sharp edge, with a good pen-knife: this cane knife cuts the gold leaf better than one of steel, as it is apt to flick to this last.

GILDING-*pallet*, a flat piece of wood, about three inches long, and an inch broad, covered with a piece of fine woollen cloth.

By breathing upon this pallet, to moisten the cloth a little, and then clapping it gently down upon the gold leaf, this may be raised from the cushion, and conveyed to the work to be gilded.

GILDING-*size*. See GILDING *of shields*.

GILEAD, *balm of*. See BALSAM.

GILEAD, *false balm of*, *Dracocephalum*, in *Botany*. See DRACOCEPHALUM.

GILGUL *hammethim*, a Hebrew phrase, literally signifying the *rolling of the dead*. To conceive the use of this superstition it is to be observed, that the Jews have a tradition that, at the coming of the Messiah, no Israelite shall rise any-where but in the Holy Land. What, then, shall become of all the faithful interred in other parts? shall they perish, and remain in the state of death?

No, *say* the Jewish doctors; but God will dig them subterraneous canals, or cavities, through which they shall roll from their tombs to the Holy Land; and, when they are arrived there, God will blow on them, and raise them again.

This imaginary passage of the cavesides, or *sluts*, of the Jews, from their tombs to the Holy Land, by rolling under-ground, is what they call *gilgul hammethim*, the rolling of the dead.

GILL. See GROUND-IVY.

GILLA, in *Chemistry* and *Pharmacy*, is an *Arabic* term for salt, peculiarly used among us for the emetic salt of vitriol.

This salt is prepared from that mineral, by three or four repeated operations; viz. dissolution, in May-dew, filtration, and crystallization. In defect of May-dew, rain-water may serve.

Gilla is used in tertians, and all fevers arising from a corruption of humours, in the first passages. It destroys worms, and prevents putrefaction. The dose is from twenty grains to half a drachm, taken in broth, or in cordial waters.

GILLAROO, *trout*. See TROUT.

GILLS, *Branchiæ*, in *Natural History*, those membranous cartilaginous parts in fishes, whereby they respire.

What we call *gills*, in fishes, serve the purposes of lungs: respiration of air is as necessary to fishes as to terrestrial animals: there is always a quantity of air included among water; and it is this air that fishes respire. The whole mechanism of their *gills* is contrived with this view; viz. to separate, and imbibe this air, from the water, and present it to the blood, after the same manner as it is presented to the lungs of other animals. All fish, therefore, have these *gills*, except the cetaceous and petromyzon.

M. Du Verney has unravelled this infinitely complicated piece of mechanism, in the *gills* of a carp: the first thing that offers is a fabric, consisting of a great number of bony laminæ, each subdivided into an infinity of bony fibres, whose office is, to sustain the innumerable ramifications of an artery dispatched thither from the heart: the use of these ramifications is, to present the blood, extremely subdivided, and, as it were, each globule of blood by itself, to the water. Between these laminæ, and throughout the whole contexture of the *gills*, are an infinite number of very narrow passages, destined to receive and subdivide the water which the fish takes in by the mouth, into little parcels. In this state the air, its prison-doors being now in some measure opened, makes its escape, and joins itself to the blood of all the little arteries.

The *gills* have necessarily an alternate motion of dilatation and compression, which is effected by another very curious piece of mechanism: when they dilate, the water is taken in; and when they contract, it is expelled again. Hence it is probable, that it is in the very infancy of contraction, that the air expelled from the water is forced to enter the pores of the little blood-vessels; because the force is then greater than at any other time; and this action requires a considerable force. The same reason holds with respect to the lungs of men: accordingly, M. Du Verney maintains, that though the air enter the lungs in the time of inspiration, it is only received into the blood in that of expiration, when the superfluous air is carried off by the trachea; so that the real inspiration, i. e. the entrance of the air into the blood, should be the expiration.

The water is taken in by the mouth, and carried off again, freed of its air, by the *gills*; and the air gained from it, is distributed, first to the arterioles of the *gills*; and thence, by the law of circulation, to all the little veins immediately therewith.

The *gills* in all fish are eight in number, four being placed on each side the throat. The lowest *gill* is always much smaller than either of the others; the other three on each side are gradually larger to the upper one, which is in all fish the largest. Every one of these *gills* is composed of a bone substance formed into a semicircle, in most kinds, or bent into the shape of a bow. On the convex side of which bone is formed a sort of plume, or the resemblance of a feather.

Each leaf (so are that word is composed of a double row of bony lamellæ, some shorter than others, and each of these lamellæ is bent to the convex part of the bow, by means of the membrane with which that bow is covered. These lamellæ have one part convex, and the other concave. The convex side is covered with numerous hairs, or papillæ, and these are longest near the base, and diminish towards the apex. They are set hairy on the concave side; the hairs there being shorter, and continued only to the middle of the lamellæ, not running all the way along it. These hairs are all the way connected to the *gill* by a very tender membranous substance which covers the lamellæ, but they are each single at the base. Artedi, Ichthyolog.

The concave part of every lamina is applied to the convex part of the next opposite lamina, and the laminæ are all connected one with another, by means of a membrane which arises at their base, and is continued by half their length; in this part the membrane becomes stronger, and forms a sort of cord. The rest of the lamina is free, and terminates in an extremely fine and flexile point. Every one of these laminæ is invested with a fine and thin membrane, and each serves to receive the ramifications of the vessels which are brought into the branchiæ. The inside of every bow or bony semicircle which makes one *gill*, gives place to one artery, one vein, and one nerve. The conformation of this hollow part of each *gill* is different in different fish; in some it contains a number of smooth tubercles, which are short, and scarce stand out beyond the surface: this is the case in the *gills* of the cyprinus, &c. In some it is in this manner beset with very rough tubercles, as in the cods; in some others these tubercles are rough, and resemble teeth, as in the salmon, &c. In some also this surface, instead of tubercles, is beset with a sort of long hairs resembling rays as in the clupea; and finally, in some this part is beset with real, but short prickles, as in the sloces. The use of the *gills* in fish seems to be to receive the blood which is protruded from the heart into the aorta, and drive it to the utmost parts of the laminæ, from whence it is returned by veins which distribute it to every part of the body, and to serve for the office of respiration. The motion of the *gills* of fish is no way so beautifully seen as in the viewing those of a small eel with a microscope. Two rows of these are always bended roundish one against the other, while their ends play against one another, touching and going back again very regularly and successively, and imitating the opening and shutting of a pair of bellows, in a regular succession; and, in the generality of fish, one pair does this, while another pair only continues advanced, so as to close with their base, and this is done alternately by one and another pair all the time that the observation is continued. Phil. Trans. N° 222.

GILLS, *apertures of the*. See BRANCHIA.

GILLS, *leaf of the*. See FOLIUM *branchiorum*.

GILLY-*flower*, or JULY-*flower*. See PINK.

GILLY-*flower*, *queen's*. See *Dame's* VIOLET.

GILLY-*flower*, *stock*. See STOCK *Gilly-flower*.

GILP *head*, *Surat*, in *Ichthyology*, the name of a broad and flat fish, not unlike the bream in shape. It sometimes grows to eight or ten pounds weight; its scales are moderately large, its back is of a blackish green, and its sides of a dusky brown, with a faint cast of yellow. At the upper angle of the coverings of the *gills* it has usually a black spot, and under that often a purple one between its eyes. It has a fine gold-coloured, arched, or lunated mark, the convex of which is toward the mouth, the points toward the eyes; and, therefore, in the *Linnæan* system it is the *sparus aureis inter oculos*. The dorsal fin extends almost the whole length of the back, and consists of twenty-four rays, the eleven first spiny, the others soft: the pectoral fins consist of seventeen soft rays; the ventral of six rays, the first of which is very strong and spiny; the anal fin of fourteen, the three first spiny; and the tail is much forked. The grinders of this fish are flat and strong, like those of certain quadrupeds; besides which they have certain bones in the lower part of the mouth, which assist in grinding their food.

It is common in the markets of Rome, Venice, &c. and caught in great plenty in the summer months in different parts of the Mediterranean; in winter it is more scarce, but more valued. Some have confounded this fish with the sea-bream or *sparus pagrus* of Linnæus. See PAGRUS.

GIMBOLS, denote the brass-rings by which a sea-compass is suspended in its box that usually stands in the GIMBALS.

GIMBLETING, in *Sea-language*, is applied to the anchor, to denote the action of turning it round by the stock, so that the motion of the flock appears similar to that of the handle of a gimblet, when it is employed to turn the wire.

GIMMER-*lamb*, or GAMMER-*lamb*, a term used for the female or ewe lamb.

GIN, in *Artillery* and *Mechanics*, is a machine for raising great weights, composed of three long legs, two of which are kept at a proper distance by means of two iron or wooden bars fixed to one of the legs by means of a bolt at one end, and by the other end to the other leg with a bolt and key, so that it may be put on or off at pleasure. At three feet from the bottom is a roller moving in cheeks, that are fastened to these poles by two iron bands and two iron bolts. The three legs of this machine are joined together

gether with an iron bolt, about which they move; to this bolt is fixed an iron half ring to hook on the windlass, containing two brass pullys. When the *gin* stands upright, and its legs are at a proper distance, one end of the cable is fixed to the dolphins of a gun or mortar with another windlass, containing likewise two brass pullys, and the other passes through the pullys and round the roller, which is turned round by means of handspikes passing through the holes in the ends of the roller: while a man holds the cable tight, the *gin* is raised to such a height as to admit a carriage being put under it.

GIN, in *Distillery*. See GENEVA.

GINETTA, or GENETTA, GENET, the VIVERRA *genetta* of Linnæus, the name of a small animal of the weasel-kind, of a tawny red colour, ornamented with several black spots in different parts of the body, and the ridge of the back marked with a black line. It is naturally a very tame and inoffensive creature. It is usually found about rivers, ferding on what it finds about their banks. It is found in some parts of Spain, and at Constantinople, and in some other parts of the Turkish dominions. It runs hoofe about the houfes like a cat, and is as ufeful in catching mice; its tail, which is long, is variegated with circles of black and tawny colours; its feet are black, its ears a little pointed, and its fkin is of a fomewhat perfumed fmell.

GINGER, *Amomum*, in *Botany*, a genus of the *monandria monogynia* clafs. Its characters are thefe: the flowers are collected in a fcaly fpike, each having a double fheath; the flower is of one leaf, tubulous below, and divided into three parts at the brim. In the bofom of the flower is fituated an oblong thick nectarium; from the tube of the flower arife two ftender ftamina, crowned with thick, fhort fummits. Under the receptacle of the flower is placed the round germen, fupporting a fingle ftyle as long as the tube of the flower, and crowned with a hairy ftigma, which afterward becomes an oval three-cornered feed-veffel, opening in three parts, containing feveral feeds. There are three fpecies.

The firft, which is the common *ginger*, is cultivated for fale in moft of the iflands in America; but is a native of the Eaft Indies, and alfo of fome parts of the Weft Indies, where it is found growing naturally without culture. The dried roots of this fort furnifh a confiderable export from the Britifh colonies in America.

The fecond fort grows naturally in India: the roots of this are much larger than thofe of the firft, but are jointed in the fame manner. The latter hath thick fleffy roots, refembling thofe of the large flag iris. Thefe forts are tender, and require a warm houfe to preferve them in this country.

They are propagated by parting the roots; the beft feafon for doing which is early in fpring, before they begin to fhoot. Every large part of the root may then be divided into feveral flips, with two or three eyes to each, all which will fucceed: thefe are to be planted feparately in pots of a light rich earth, and plunged into a hot-bed of tanners bark, where they muft be fparingly watered, till their ftalks appear above ground; afterwards, during the fummer months, more plentifully; but in autumn and winter lefs frequently; and in hot weather muft often have the glaffes taifed with a brick to give them air. They will increafe greatly at the root, and fometimes flower with us; but they muft be kept in the hot-bed all the fummer, and in winter be removed into the ftove. Miller.

When arrived at maturity, they dig the root up, and dry it on hurdles, either in the fun, or an oven: the beft is that which is new, dry, well filled, hard to break, of a brownifh colour without, refinous within, and of a hot, pungent taffe.

They ufe to candy the root, when green, with fugar and honey; having firft fteeped it fome time in water, to take away part of its acrimony, and to difpofe it to let go the outer fkin. They alfo make a marmelade of it, and dry cakes.

The northern people make great ufe of this confection, as holding it fovereign againft the fcurvy. The Indians eat the root, when green, by way of fallad, firft chopping it fmall, mixing it with other herbs, and feafoning it with oil and vinegar.

This warm aromatic root appears to be much lefs liable to heat the conftitution than might be expected from the penetrating heat and pungency of its taffe, and the fubtilties of its active principles. It gives part of its virtue to water, and the whole to rectified fpirit, tinging the latter of a deep, and the former of a pale yellow colour. In the fhops is kept a fyrup made from an infufion of three or four ounces of the root in three or four pints of boiling water, which is agreeably impregnated with its warmth and flavour; and the candied *ginger*, brought from abroad, which is likewife moderately aromatic. Lewis.

As to its medicinal ufe, it is hot and penetrating; it is alfo held good to ftrengthen the ftomach, and promotes appetite: it promotes alfo digeftion, prevents putrefaction, &c. and is an ingredient in many of the compofitions, and powders of the fhops.

Ginger may be preferved by waffhing it, and boiling it to fteep for ten or twelve days in white wine and water, ftirring them every day; then boil a pound of roots with two quarts of white wine, and about a pint of lemon juice, for a quarter of an hour; then add two pounds and a half of fine fugar, and boil it to a fyrup, fcumming it as it rifes; fet it by till the next day in a glazed pan; then boil it for half an hour, and repeat this boiling at the fame interval till the *ginger* is clear. Put it into glaffes, and cover them with paper, and it will afford a fine fweet meat for the winter feafon.

GINGERBREAD, a richer kind of bread; the flavour and taffe whereof are heightened and improved with fpices, and particularly *ginger*; whence the name.

There are various forms and preparations of *gingerbread*: we fhall content ourfelves with the following receipt, which is well recommended.

Into a pound of almonds, blanched and pounded, grate a penny white loaf; fift and beat them together; to the mixture add an ounce of ginger, fcraped fine; and liquorice, and aniffeed in powder, of each a quarter of an ounce; pour in two or three fpoonfuls of rofe-water, and make the whole into a paffe, with half a pound of fugar; mould and roll it, print it, and dry it in a ftove. Others make it of treacle, ritron, lemon, and orange-peel; with candied *ginger*, coriander, and caraway-feeds, mixed up with as much flour as will make it into a paffe.

GINGIBRACHIUM, a name given by fome medicinal authors to the fcurvy, when it affects the arms and other extremities.

GINGIDIUM. See ARTEDIA.

This is alfo a term ufed by *Botanifts* for a fpecies of FENNEL.

GINGIPEDIUM, a name given by fome authors to the fcurvy when it affects the feet.

GINGIVA, in *Anatomy*, the GUM; a hard fort of fleffy, inveiling the alveoli, or fockets, of the teeth.

The *gingivæ* are formed by the union of two membranes; one of which is a production of the periofteum, and the other of the internal membrane of the mouth.

GINGLYMUS, *Ἐγγλυμος*, in *Anatomy*, one of the fpecies of articulation.

The *ginglymus* is that jointure of the bones where each bone mutually receives the other; fo that each bone both receives, and is received.

There are three fpecies of *ginglymus*: the firft, when the fame bone, at the fame extremity, receives, and is reciprocally received by another bone, after the manner of a hinge; fuch is that of the cubitus and humerus.

The fecond, when a bone receives another at one of its extremes; and is received into another, at the other; as the vertebræ do.

The third is that where a bone is received into another, after the manner of a wheel, or the axis of a wheel, in a box; fuch is that of the fecond vertebra of the neck in the firft.

GINGRA, in *Antiquity*, a kind of dance ufed at funerals.

GINGRINA, in *Antiquity*, a name given to a fmall kind of flute for beginners.

GINORA, in *Botany*, a genus of the *dodecandria digynia* clafs: the characters of which are, that the calyx is divided into fix fegments; the number of petals is fix; and the fruit is a fingle veffel, four-valved, colonized, polyfpermous capfule.

GIN-SENG, or NIN-SENG, *Panax*, in *Botany*, a genus of the *polygamia dioecia* clafs. Its characters are thefe: it hath male and hermaphrodite flowers on diftinct plants; the male have fimple globular umbels, compofed of feveral coloured rays, which are equal; the flower has five narrow, oblong, blunt petals, which are reflexed, fitting on the empalement, and five oblong, ftender ftamina inferted in the empalement, terminated by fingle fummits; the hermaphrodite umbels are fimple, equal, and cluftered; the involucrum is fmall, permanent, and compofed of feveral awl-fhaped leaves; the flowers have five oblong equal petals, which are recurved, and five fhort ftamina, terminated by fingle fummits, which fall off, with a roundifh germen under the empalement, fupporting two fmall erect ftyles, crowned by fimple ftigmas; the germen afterwards becomes an umbellicated berry with two cells, each containing a fingle, heart-fhaped, convex, plain feed. There are two fpecies, both of which grow naturally in North America; one of them is believed to be the fame with the Tartarian *ginfeng*, the figures and defcription of that plant, which have been

sent to Europe by the missionaries, agreeing perfectly with the American plant.

This hath a fleshy taper root, as large as a man's finger, which is jointed, and frequently divided into two smaller fibres downward: the stalk rises above a foot high, naked to the top, where it generally divides into three smaller foot-stalks, each sustaining a leaf composed of five spear-shaped lobes, which are sawed on their edges; they are of a pale green and a little hairy: the flowers arise on a slender foot-stalk, just at the division of the foot-stalks which sustain the leaves, and are formed into a small umbel at the top; they are of a herbaceous yellow colour, composed of five small petals, and recurved: these appear the beginning of June, and are succeeded by compressed heart-shaped berries, which are first green, but afterward turn red, including two hard, compressed, heart-shaped seeds, which ripen in the beginning of August. Miller.

The *gin-seng* is one of the principal medicines of the Chinese and Tartars; and their most eminent physicians have written many volumes concerning its virtues.

It is known among them by divers other names, expressing only *spirit*, or *the pure spirit of the earth*; *the plant that gives immortality*, &c. It makes, in effect, the whole materia medica for the people of condition, but is too precious for the populace.

All the writers of the Chinese affairs make mention of the *gin-seng*: as Martinius, in his Atlas; F. Kercher, in his China Illustrata; F. Tachard, in his Voyages; and F. Le Comte, in his Memoirs.

And yet we know but very little of this plant before F. Jartoux, a Jesuit, and missionary in China; who, being employed, by order of the emperor, in making a map of Tartary, in the year 1709, had an opportunity of seeing it growing, in a village about four leagues from the kingdom of Corea, inhabited by Tartars, called *Calin-Tatze*.

That father took this opportunity to make a draught of the plant, and give an accurate description thereof, with its virtues and manner of preparing it; which, being a great curiosity, we shall here gratify the reader with.

The *gin-seng*, represented *Tab. Nat. Hiſtory, fig.* 10. has a white root, somewhat knotty, about thrice the thickness of the stem, and which goes tapering to the end; at a few inches from the head it frequently parts into two branches, which gives it some resemblance of a man, whose thighs the branches represent; and it is hence it takes the denomination *gin-seng*, which signifies a figure of a man.

It is hard to say, why the Chinese should call it *gin-seng*, a word which signifies *figure*, or *representation of a man*: neither that father, nor any he enquired of, could ever find that it bore more resemblance to the figure of a man than is ordinarily seen among other roots. The Tartars, with more reason, call it *orhota*, that is, the first of plants. It grows to the height of about eighteen inches.

The plant dies away every year: the number of its years may be known by the number of stalks it has shot forth, of which there always remains some mark, as is shewn in the figure by the letters *b b b*, &c. from whence it appears that the root A was seven years old.

Those who gather the *gin-seng* preserve only the root, and all they can get of it in ten or fifteen days time they bury together, in some place under ground; then they take care to wash it well, and scour it with a brush; then dry it in scalding water, and prepare it in the fumes of a sort of yellow millet, which gives it part of its colour. The millet is put in a vessel, with a little water, and boiled over a gentle fire; the roots are laid over the vessel, upon small transverse pieces of wood, being first covered with a linen cloth, or some other vessel placed over them.

They may also be dried in the sun, or by the fire; but then, though they retain their virtue well enough, they have not that yellow colour which the Chinese so much admire. When the roots are dried, they must be kept close in some very dry place; otherwise they are in danger of corrupting, or of being eaten by worms. The method of curing *gin-seng* is described in the Med. Transf. vol. iii. p. 35.

As to the place where this root grows, it is between the thirty-ninth and forty-seventh degree of north latitude, and between the tenth and twentieth degree of east longitude, reckoning from the meridian of Pekin. Here is found a long tract of mountains, which thick forests, that cover and encompass them, render almost impassable: it is upon the declivities of these mountains, and in these thick forests, upon the banks of torrents, or about the roots of trees, and amidst a thousand other different sorts of plants, that the *gin-seng* is found; it is not to be met with in plains, valleys, marshes, the bottoms of rivulets, or in places too much exposed and open.

If the forest takes fire and be consumed, this plant does not appear till two or three years after; it also lies hid from the sun as much as possible, which shews that heat is an enemy to it.

The places where the *gin-seng* grows are, on every side, separated from the province of Quan-tong by a barrier of wooden stakes, which encompasses this whole province, and about which guards continually patrol, to hinder the Chinese from going out and looking after this root. Yet, how vigilant soever they are, greatness after gain incites the Chinese to look about privately in these deserts, sometimes to the number of two or three thousand, at the hazard of losing their liberty, and all the fruits of their labour, if they are taken either as they go out of, or come into the province.

The emperor, in order that the Tartars should reap all the advantage that is to be made of this plant rather than the Chinese, gave orders, in 1700, to ten thousand Tartars, to go and gather all they could find of the *gin-seng*, upon condition that each person should give him two ounces of the best, and that the rest should be paid for, weight for weight, in pure silver.

It was computed, that, by this means, the emperor would get this year above twenty thousand Chinese pounds of it, which would not cost him above one fourth part of its value.

We met, by chance, says F. Jartoux, with some of those Tartars, in the midst of those frightful deserts, and their mandarins, who were not far out of the way, came, one after another, and offered us oxen for our subsistence, according to the commands they had received from the emperor.

This army of herbalists observed the following order: after they had divided a certain tract of land among their several companies, each company, to the number of a hundred persons, spread itself out in a right line, to a certain fixed place, every ten of them keeping at a distance from the rest.

Then they searched carefully for the plant, going on leisurely in the same order; and in this manner, in a certain number of days, they run over the whole space of ground appointed them.

When the time was expired, the mandarins, who were encamped in their tents in such places as were proper for the subsistence of their horses, sent to view each troop, to give them fresh orders, and to inform themselves if their number was complete.

If any one of them was wanting, as it often happened, either by wandering out of the way, or being attacked by wild beasts, they always looked for him a day or two, and then returned again to their labour as before.

The *gin-seng*, we have observed, is an ingredient in most of the medicines which the Chinese physicians prescribe to the better sort of patients: they affirm, that it is a sovereign remedy for all weaknesses occasioned by excessive fatigues, either of body or mind; that it attenuates and carries off pituitous humours; cures weakness of the lungs and the pleurisy; stops vomitings; strengthens the stomach, and helps the appetite; dispersles fumes or vapours; fortifies the breast; is a remedy for short and weak breathing; strengthens the vital spirits, and is good against dizziness of the head and dimness of sight; and that it prolongs life to extreme old age. Nobody can imagine, that the Chinese and Tartars would set so high a value upon this root, if it did not constantly produce a good effect: those that are in health often make use of it to render themselves more vigorous and strong. And I am persuaded, says the father just mentioned, it would prove an excellent medicine in the hands of any European who understands pharmacy, if he had but a sufficient quantity of it to make such trials as are necessary to examine the nature of it chemically, and to apply it to a proper quantity, according to the nature of the disease for which it may be beneficial.

It is certain, that it fortifies, increases the motion of and warms the blood, that it helps digestion, and invigorates in a very sensible manner.

After I had designed the root, he goes on, I observed the state of my pulse, and then took half of a root, raw as it was, and unprepared; in an hour after I found my pulse much fuller and quicker; I had an appetite, and perceived myself much more vigorous, and could bear labour better and easier than before. Four days after, finding myself to fatigued and weary, that I could scarce sit on horseback, a mandarin, who was in company with us, perceiving it, gave me one of these roots; I took half of it immediately, and an hour after I was not in the least sensible of any weariness. I have often made use of it since, and always with the same success. I

have observed alſo, that the green leaves, and eſpecially the ſiſhous part of them, chewed, would produce nearly the ſame effect. The Tartars often bring people the leaves of *gin-ſeng* inſtead of tea; and I always find myſelf ſo well after words, that I ſhould readily prefer them before the beſt tea: their decoction is of a grateful colour, and, when one has taken it twice or thrice, its taſte and ſmell become very agreeable.

As for the root, it is neceſſary to boil it a little more than tea, to allow time for extracting its virtue, as is practiſed by the Chineſe, when they give it to ſick perſons; on which occaſion they uſually uſe more than the fifth part of an ounce of the dried root.

To prepare the root for exhibition they cut it into thin ſlices, and put it into an earthen pot well glazed, with about half a pint of water; the pot is to be well covered, and ſet to boil over a gentle fire; and, when the water is conſumed to the quantity of a cup full, a little ſugar is to be mixed with it, and to be drank; immediately after this, as much more water is to be put to the remainder, and to be boiled as before, to extract all the juice, and what remains of the ſpirituous part of the root.

Theſe two doſes are to be taken, the one in the morning, and the other in the evening. Phil. Tranſ. N° 337. or Abridg. vol. iv. part ii. p. 314, &c.

The *gin-ſeng* root, though far unequal to the character that has been commonly given of it, promiſes, from its ſenſible qualities, to be an uſeful addition to the officinal drugs. To the taſte it diſcovers a mucilaginous ſweetneſs, approaching to that of liquorice, accompanied with ſome degree of bitteriſhneſs, and a ſlight aromatic warmth, with little or no ſmell. The ſweet matter of the *gin-ſeng* is preſerved entire in the watery as well as in the ſpirituous extract; and the ſlight aromatic impregnation is partly reſolved in the former, and perfectly in the latter, which laſt is a very pleaſant, buttereſh, warm ſweet. Lewis.

GIOAR, in the *Materia Medica* of the ancient Arabians, a word applied to ſeveral different ſubſtances, and ſometimes uſed as the diſtinct names of them; ſometimes only as an epithet to them. It is generally uſed by Avicenna as a name for arſenic, ſometimes for antimony; and in Serapion, we often find it ſtanding for any of the mineral poiſons. The original meaning of the word is no more than what the Greeks expreſſed by the word ἀρσ. *ſubſtance*; but it became applied to ſeveral things moſt eminent in their way; as to arſenic, the moſt fatal of poiſons; to antimony, ſuppoſed at that time the moſt valuable of medicines; and to pearls as the moſt valuable of gems.

GIOMELLI, a body of the ſpahis, or horſe, in the ſervice of the grand ſignior.

GIR, a name by which ſome of the chemical writers have called quick-lime.

GIRAFFE, or *Camelopardal*, in *Zoology*. See *Tab. Quadrupeds, fig.* 7. and CAMELOPARDAL.

GIRANDOLE, a large kind of branched candleſtick. See BRANCH and JESSE.

GIRDERS, in *Architecture*, the largeſt pieces of timber in a floor. Their ends are uſually faſtened into the ſummers, or breſt-ſummers; and the joiſts are framed in at one end to the *girder*.

By the ſtatute for rebuilding London, no *girder* is to lie leſs than ten inches into the wall, and their ends to be always laid in loam, &c.

GIRDING-*beams*, in *Building*, the ſame as GIRDERS.

GIRDING-*ſtrap*, in *Sea-language*. The ſeamen ſay a ſhip is *girt*, or hath a *girding-girt*, when her cable is ſo tight or ſtrained, that upon the running of the tide ſhe cannot go over it with her ſtern part, but will lie across the tides.

GIRDLE, *Cingulum*, or *Zona*, a belt or band of leather, or other matter, tied about the reins, to keep that part more firm and light.

It was anciently the cuſtom for bankrupts, and other inſolvent debtors, to put off and ſurrender their *girdle* in open court. The reaſon hereof was, that our anceſtors uſed to carry all their neceſſary utenſils, as purſe, keys, &c. tied to the *girdle*; whence the *girdle* became a ſymbol of the eſtate. Hiſtory relates, that the widow of Philip I. duke of Burgundy, renounced her right of ſucceſſion by putting off her *girdle* upon the duke's tomb. The Romans always wore a *girdle*, to tuck up the tunics when they had occaſion to do any thing: this cuſtom was ſo general, that ſuch as went without *girdles*, and let their gowns hang looſe, were reputed idle, diſſolute perſons.

GIRDLE, *Maldon* or *Virgin*. It was the cuſtom among the Greeks and Romans, for the huſband to untie his wife's *girdle*. Homer, lib. xi. of his Odyſſey, calls the *girdle* ζωστῆρα ἅμα, *ſimul girdle*. Feſtus relates, that it was made of ſheep's wool, and that the huſband untied it in bed: he adds, that it was tied in the Herculean knot; and that the huſband untied it, as a happy preſage of his having as many children as Hercules, who at his death, left ſeventy behind him.

The poets attribute to Venus a particular kind of *girdle*, called CESTUS, to which they annexed a faculty of inſpiring the paſſion of love.

GIRDLE, *quickſilver*, in *Mechaniſm*, is a ſort of *girdle*, ſmeared over with mercury, or having mercury incloſed within it.

It is made of leather, linen cloth, cotton, fluff, or the like; and the mercury is prepared or killed various ways; as with faſting ſpittle, &c. or the like.

It is applied as a topical medicine about the waiſt, ſometimes with good effect; but, frequently, it proves dangerous, principally in weak conſtitutions, and thoſe ſubject to convulſions. Its intention is, the cure of the itch, driving away vermin, killing lice, &c.

GIRDLE, *Queen's*, is an ancient duty or tax, raiſed at Paris every three years, at the rate of three deniers upon each muid of wine, and ſix for each queen: it was intended for the maintenance of the queen's houſhold; afterwards they augmented and extended it to other commodities, as coals, &c.

Vigenere ſuppoſes it to have been originally thus called, becauſe the *girdle* anciently ſerved for a purſe; but he adds, that a like tax had been raiſed in Perſia, and under the ſame name, above two thouſand years ago; as appears from Plato, in his Alcibiades, Cicero, Athenæus, &c.

GIRDLE, *Chriſtians of the*, Motawekkel, tenth Caliph of the family of the Abaſſides, enjoined the Chriſtians and Jews, in the year of the Hegira 235, of Jeſus Chriſt 856, to wear a large leathern *girdle*, as a badge of their profeſſion; which they bear to this day throughout the Eaſt; from which time the Chriſtians of Aſia, and particularly thoſe of Syria and Meſopotamia, who are almoſt all Neſtorians or Jacobites, have been called *Chriſtians of the Girdle*.

GIRDLE, *order of the*, the order of Cordeliers. See CORD and CORDELIER.

GIRDLE, in *Architecture*. See CINCTURE.

GIRDLE, among *Jewellers*, the line which encompaſſes the ſtone, parallel to the horizon; or, which determines the greateſt horizontal expanſion of the ſtone.

GIRDLE-*wheel*, a ſmall ſpinning-wheel, made for handling to a woman's girdle or apron-ſtring, ſo that ſhe may ſpin with it though walking about.

GIRGILIM, in the *Materia Medica*, a name given by ſome authors to the ſeſamum, or oily purging grain.

GIRGITES, a name uſed by ſome chemical writers for a ſort of white ſtones found in rivers, of which they make a peculiarly fluxing lime. The ſtones are of the ſparry kind, worn into roundneſs by the motion of the water; and they have their name *girgites*, from the word *gir*, uſed by the chemiſts for lime.

GIRKIN, among *Gardeners*. See GHERKIN.

GIRLE, among *Sportſmen*, denotes the roe-buck in its ſecond year.

GIRMER, a word uſed by ſome of the chemical writers to ſignify tartar.

GIRON, or GUIRON, in *Heraldry*, denotes a triangular figure, having a long ſharp point, not unlike a wedge, terminating in the centre of the eſcutcheon.

The word is French, and literally ſignifies the *gore-cloth*, or *lap*, becauſe, in ſitting, the knees being ſuppoſed ſomewhat aſunder, the two thighs, together with a line imagined to paſs from one knee to the other, form a figure ſomewhat ſimilar to this.

When a coat has ſix, eight, or ten of theſe *girons*, meeting or centring in the middle of the coat, it is ſaid to be *gironne* or *gironny*.

GIRROCK, the common Engliſh name of the ſiſh called the LUMPUS, a large ſpecies of gar-ſiſh, caught in the Mediterranean and Engliſh ſeas.

GIRONNE, GIRONNY, in *Heraldry*, is when a ſhield or coat is divided into ſeveral girons, which are alternately colour and metal. See *Tab.* II. *Herald. fig.* 63. which is blazoned *gironné* of ſix argent and ſable.

When there are eight pieces, or girons, it is abſolutely ſaid to be *gironné*; when there are more, or fewer, the number is to be expreſſed: *gironné* of four, of fourteen, &c.

Some,

Some, instead of *girouni*, fay, *parti*, *cruppli*, *trunchi*, and *taili*, because the girons are formed by fuch divifions of the field. Four girons form a SALTIER, and eight a croſs.

GIRT, in meaſuring TIMBER, is uſed for the circumference of a tree. See *Coggeſhall*'s SLIDING-*rule* and DENDROMETER.

Some call the fourth part of the circumference the *girt*, and ſuppoſe the ſquare of this equal to the area of the ſection of the tree.

GIRT, in *Architecture*, the ſame with fillet. See FILLET.

GIRT, *girdle*, in *Sea Language*. See GIRDING-*girt*.

GIRT-*line* is a rope paſſing through a ſingle block, on the head of the lower maſts, to hoiſt up the rigging thereof: this is the firſt rope employed to rig a ſhip, and by means of this all the reſt are drawn up and fixed; after which it is removed until the ſhip is to be unrigged.

GIRTHS *of a ſaddle*, the ſtrong ſtraps, made of a canvas ſtuff called *girth*-web, which being buckled under the horſe's belly, ſerves to fix the SADDLE.

GISARMS, or GUISARMES, in *our Old Writers*, an halbert or hand-ax: it comes from the Latin *bis arma*, becauſe it wounds on both ſides. Skene. *Eſt armorum genus longo manubrio & parvella cuſpide*. It is mentioned in the ſtatute 13 Edw I. cap. 6.

GISCARA, a name uſed by ſome botanical authors for the *palma ſemina minor Breſilienſis*, a ſmall palm common in the Braſils.

GISON, or GESON, in the *Jewiſh Antiquities*, a little wall about breaſt high, made round the temple properly ſo called, and the altar of burnt ſacrifices, to keep the people at a diſtance. Joſephus, in his Book of Antiquities, makes it to be three cubits high; and but one, in his Hiſtory of the Jewiſh war. Joſ. Antiq. lib. viii. cap. 2. p. 362. & De Bello Jud. lib. vi. p. 918. Calm. Dict. Bibl.

GITHAGO, in *Botany*, a name uſed by ſome authors, particularly by Pliny, for the lolium or darnel-graſs.

GITTITH. This word occurs frequently in the Pſalms, and is generally tranſlated *wine-preſſes*. The conjectures of interpreters are various concerning this word *gittith*. Some think it ſignifies a ſort of muſical inſtrument; others, that the Pſalms, with this title, were ſung after the vintage; laſtly, others, that the hymns of this kind were invented in the city of Gath. Calmet is rather of opinion, that it was given to the claſs of young women, or ſongſtreſſes of Gath, to be ſung by them. Pſ. viii. 1. Inſcript. Habac. 1. Dr. Hammond thinks that the Pſalms, with this title, were all ſet to the ſame tune, and made on Goliah the Gittite.

GIVEN, *datum*, a term very frequently uſed in *Mathematics*, ſignifying a thing which is ſuppoſed to be known.

Thus, if a magnitude be known, or we can find another equal to it, we ſay, it is a *given* magnitude, or that ſuch a thing is *given in* magnitude.

If the poſition of any thing be ſuppoſed as known, we ſay, *given* in poſition.

Thus if a circle be actually deſcribed on a plane, its centre is *given* in poſition, its circumference *given* in magnitude, and the circle is *given* both in poſition and magnitude.

A circle may be *given* in magnitude only; as when only the diameter is *given*, and the circle not actually deſcribed.

If the kind or ſpecies of any figure be given, they ſay, given in ſpecies. If a ratio between any two quantities is known, they are ſaid to be *given* in proportion. See DATA.

GLAUX, in the *Materia Medica* of Galen and the ancients, a name given to the fineſt and beſt kind of caſſia fiſtula. The ancients had ſeveral ſorts of this drug, ſome collected ſeparate from the wood, ſome with it; the young ſhoots being cut bark and all, and preſerved together.

GLABELLA, *ſmall glabra*, a term uſed by ſome writers to expreſs the ſpace between the two eye-brows: it is ſo called from its ſmoothneſs, being uſually without hair.

GLACIALIS, icy, of *glacies*, *ice*, ſomething relating to ice; and particularly a place that abounds in ice.

Thus we ſay, the *Mare Glaciale*, or *Congelatum*, that is, the Icy or Frozen Sea; called alſo the Chronian or Sarmatian Sea.

GLACIES *Mariæ*. See SPECULARIS *lapis*.

GLACIS, in *Building*, an eaſy inſenſible ſlope or declivity. The deſcent or inclination of the *glacis* is leſs ſteep than that of the talut. In gardening, a deſcent ſometimes begins in talut, and ends in *glacis*.

The *glacis* of the cornich is an eaſy imperceptible ſlope in the cymatium of the cornich, to promote the deſcent and draining off of the rain-water.

GLACIS, in *Fortification*, is particularly uſed for that of the counterſcarp, being a ſloping bank, which reaches from the parapet of the counterſcarp, or covert-way, to the level ſide of the field, at the diſtance of about twenty fathoms. See *Tab. Fort. fig.* 21. *lit. a a a* and *z*.

The conſtruction of the covert-way and *glacis* is more diſtinctly illuſtrated in Tab. VII. *Fortif. fig.* 42. When the body of the place, and all the neceſſary out-works are conſtructed, lines are drawn parallel to the outermoſt counterſcarp of the ditches, at ſix toiſes diſtant from it; and the ſpace *m m n*, included between theſe two and the counterſcarp, will be the COVERT-way required. If lines are drawn parallel to the lines which terminate the covert-way, and the places of arms *n*, *n*, &c. at twenty toiſes diſtant from them, the ſpace *z z z*, between theſe lines will be the *glacis*. A, in this figure, repreſents the ARROW; B, the *detached* REDOUBT; C, C, the TRAVERSES; *z z z*, the SALLY-*ports*. When the ground is low, and water to be found, there is often a ditch of about ten or twelve toiſes made round the *glacis*; beyond which there is a ſecond covert-way of four toiſes, with traverſes and places of arms, and a ſecond *glacis* from fifteen to eighteen toiſes broad. Muller's Fort. p. 42.

GLADDON, or GLADWIN, the name of a plant otherwiſe called SOURGE-*wort*.

GLADE, in *Agriculture*, *Gardening*, &c. a viſta, or open and light paſſage made through a thick wood, grove, or the like, by lopping off the branches of trees along the way.

GLADE, in *Zoology*. See GLEAD.

GLADIATORS, in *Antiquity*, perſons who were retained to fight ordinarily in the arena, for the entertainment of the people.

The *gladiators* were uſually ſlaves, and fought out of neceſſity: though, ſometimes, freemen made profeſſion thereof, like our prize-fighters, for a livelihood. After a SLAVE had ſerved on the arena three years, he was diſmiſſed.

The Romans borrowed this cruel diverſion from the Aſiatics: ſome ſuppoſe that there was policy in this practice, the frequent combats of *gladiators* tending to accuſtom the people to deſpiſe dangers and death.

The origin of ſuch combats ſeems to be as follows: from the earlieſt times with which we have any acquaintance in prophane hiſtory, it had been the cuſtom to ſacrifice captives, or priſoners of war, to the manes of the great men who had died in the engagement: thus Achilles, in the Iliad, lib. xxiii. ſacrifices twelve young Trojans to the manes of Patroclus; and in Virgil, lib. xi. ver. 81. Æneas ſends captives to Evander, to be ſacrificed to the funeral of his ſon Pallas.

In courſe of time they came alſo to ſacrifice ſlaves at the funerals of all perſons of condition; this was even eſteemed a neceſſary part of the ceremony; but, as it would have appeared barbarous to have maſſacred them like beaſts, they were appointed to fight with each other, and endeavour to ſave their own lives by killing their adverſary. This ſeemed ſomewhat leſs inhuman, becauſe there was a poſſibility of avoiding death, by an exertion of ſkill and courage.

This occaſioned the profeſſion of *gladiator* to become an art: hence aroſe maſters of arms, and men learned to fight and exerciſe this art.

Theſe maſters, whom the Latins called *laniſtæ*, bought them ſlaves to be trained up to this cruel trade, whom they afterwards ſold to ſuch as had occaſion to preſent the people with ſo horrible a ſhew.

They were at firſt performed near the ſepulchre of the deceaſed, or about the funeral pile; but were afterwards removed to the circus and amphitheatres, and became ordinary ſpectacles.

The firſt ſhew of *gladiators*, called *munus gladiatorum*, was exhibited at Rome, according to Valerius Maximus, by M. and D. Brutus, upon the death of their father, in the year of the city 490. On this occaſion there were probably only three pair of *gladiators*: in the year of Rome 537, the three ſons of M. Æmilius Lepidus the augur, who had been three times conſul, entertained the people with the cruel pleaſure of ſeeing twenty-two *gladiators* fight in the forum. In the year of Rome 547, the firſt Africanus diverted his army at New Carthage with a ſhew of *gladiators*, which he exhibited in honour of his father and uncle, who had begun the reduction of Spain. In proceſs of time, the Romans became ſo fond of theſe bloody entertainments, that not only the heir of any great and rich citizen lately deceaſed, but all the principal magiſtrates, preſented the people with ſhews of this nature, to procure their affection. The ædiles, prætors, conſuls, and, above all, the candidates for offices, made their court to the people, by entertaining them frequently with theſe fights: and the prieſts were ſometimes the exhibitors of the barbarous ſhews: for we meet with the *ludi pontificales* in Suetonius, Auguſt. cap. 44. and with the *ludi ſacerdotales*, in Pliny, Epiſt. lib. vii. As for the emperors, it was ſo much their intereſt to ingratiate themſelves with the populace, that they obliged them with combats of *gladiators* almoſt upon all occaſions; and as theſe increaſed, the number of combatants increaſed

ceased likewise. Accordingly, Julius Cæsar, in his ædileship, diverted the people with three hundred and twenty couple. Titus exhibited a shew of *gladiators*, wild beasts, and representations of sea-fights, which lasted a hundred days; and Trajan continued a solemnity of this nature for a hundred and twenty-three days, during which time he brought out a thousand pair of *gladiators*. Before this time, under the republic, the number of *gladiators* was so great, that when the conspiracy of Catiline broke out, the senate ordered them to be dispersed into the garrison and secured, lest they should have joined the disaffected party. See GLADIATOR'S war.

These sports were become so common, and their consequences, in a variety of respects, so dangerous, that Cicero preferred a law, that no person should exhibit a shew of *gladiators* within two years before he appointed candidate for any office. Julius Cæsar ordered, that only a certain number of men of this profession should be in Rome at a time. Augustus decreed, that only two shews of *gladiators* should be presented in a year, and never above sixty couple of combatants in a shew. And Tiberius provided, by an order of the senate, that no person should have the privilege of gratifying the people with such a solemnity, unless he was worth four hundred thousand sesterces. They were also considerably regulated by Nerva.

The emperor Claudius restrained them to certain occasions; but he soon afterwards annulled what he decreed, and private persons began to exhibit them at pleasure, as usual; and some carried the brutal satisfaction so far as to have them at their ordinary feasts.

And not slaves only, but other persons, would hire themselves to this infamous office.

The master of the *gladiators* made them all first swear, that they would fight to death; and if they failed, they were put to death, either by fire, or swords, clubs, whips, or the like.

It was a crime for the wretches to complain when they were wounded, or to ask for death, or seek to avoid it, when overcome; but it was usual for the emperor, or the people to grant them life, when they gave no figns of fear, but waited the fatal stroke with courage and intrepidity: Augustus even decreed, that it should always be granted them.

From slaves and freedmen, the inhuman sport at length spread to people of rank and condition; so that Augustus was obliged to issue a public edict, that none of the senatorian order should become *gladiators*; and soon after he laid the same restraint on the knights: nevertheless, Nero is related to have brought upwards of four hundred senators, and six hundred Roman knights upon the arena; though Lipsius takes both these numbers to be falsified, and, not without reason, reduces them to forty senators, and sixty knights: yet Domitian, that other monster of cruelty, refined upon Nero, exhibiting combats of women in the night-time.

Constantine the Great is said to have first prohibited the combats of *gladiators* in the East; at least, he forbad those who were condemned to death for their crimes, to be employed; there being an order still extant to the præfectus prætorii, rather to send them to work in the mines in lieu thereof; it is dated at Berytus, in Phœnicia, the first of October, 325.

The emperor Honorius forbad them at Rome, on occasion of the death of Telemachus, who coming out of the East into Rome, at the time of one of these spectacles, went down into the arena, and used all his endeavours to prevent the *gladiators* from continuing the sport; upon which the spectators of that carnage, fired with anger, stoned him to death.

It must be observed, however, that the practice was not entirely abolished in the West before Theodoric, king of the Oltrogoths. Honorius, on the occasion first mentioned, had prohibited them; but the prohibition does not seem to have been executed. Theodoric, in the year 500, abolished them finally.

Some time before the day of battle, the person who presented the people with the shews, gave them notice thereof, by programmas, or bills, containing the names of the *gladiators*, and the marks whereby they were to be distinguished; for each had his several badge, which was, most commonly, a peacock's feather, as appears from the scholiast of Juvenal, on the 158th verse of the third satire, and Turnebus Advers. lib. ii. cap. 8.

They also gave notice what time the shews would last, and how many couples of *gladiators* there were; and it even appears, from the 52d verse of the seventh Satire of the second book of Horace, that they sometimes made representations of these things in painting, as is practised among us by those who have any thing to shew at fairs.

The day being come, they began the entertainment by bringing two kinds of weapons; the first were staves, or wooden files, called *rudes*; and the second were effective weapons, as swords, poniards, &c.

The first were called *arma lusoria*, or *exercitoria*; the second *decretoria*, as being given by decree or sentence of the prætor, or of him at whose expence the spectacle was exhibited. They began to fence or skirmish with the first, which was to be the prelude to the battle; and from these, when well warmed, they advanced to the second, at the sound of the trumpets, with which they fought naked.

Then they were said *certare arma*, the terms of striking were *petere* & *repetere*; of avoiding a blow, *cavere*; and when one of the combatants received a remarkable wound, his adversary or the people cried out *habet*, or *habet habet*.

The first part of the engagement was called *ventilare*, *præludere*; and the second, *dimicare ad certum*, or *certa arma pugnare*: and some authors think, with much probability, that it is to these two kinds of combat that St. Paul alludes, in the passage 1 Cor. ix. 26, 27. "I fight "not as one that beateth the air; but I keep my body, "and bring it into subjection."

If the vanquished surrendered his arms, it was not in the victor's power to grant him life; it was the people, during the time of the republic, and the prince or people, during the time of the empire, that were alone impowered to grant the boon.

The reward of the conqueror was a branch of palm-tree, and a sum of money, probably collected among the spectators; sometimes they gave him his congé, or dismissed him, by putting one of the wooden files or rudes in his hand; and sometimes they even gave him his freedom, putting the pileus on his head.

The sign, or indication, whereby the spectators shewed that they granted the favour, was *premere pollicem*, which M. Dacier takes to be a clenching of the fingers of both hands between one another, and to holding the two thumbs upright close together; and, when they would have the combat finished and the vanquished slain, they *tertebant pollicem*, bent back the thumb; which we learn from Juvenal, Sat. iii. ver. 36.

The *gladiators* challenged or defied each other, by shewing the little finger; and, by extending this, or some other, during the combat, they owned themselves vanquished, and begged mercy from the people: *Victi ejusdem digiti venium a populo postulabant*, says the old scholiast on Persius. Vide Plin. lib. xxviii. cap. 2. Prudentius, lib. ii. contra Symm. ver. 1098. Horace, lib. iv. 18. ver. 66. Pollian. Miscel. cap. 42. Turneb. Advers. lib. 26. cap. 6. Lipf. Saturn. lib. ii. cap. 21.

There were divers kinds of *gladiators*, distinguished by their weapons, manner, and time of fighting, &c. as, the *andabatæ*, of whom we have already given an account under ANDABATÆ.

The *catervarii*, who always fought in troops or companies, number against number; or, according to others, who fought promiscuously, without any certain order. Lipf. lib. ii. cap. 16.

The *consummati*, whom authors mention as a species of *gladiators*, the same with the ruditæ and veterani; founding the opinion on a passage in Pliny, lib. viii. cap. 7. But Lipsius shews, that they have mistaken Pliny. Saturn. lib. ii. cap. 16. and Turnebus Advers. lib. xxi. cap. 36.

The *cubicularii*, which are a little precarious, being chiefly founded on a passage in Lampridius, in the life of the emperor Commodus: *Inter hæc, bellua vastissima, vastissimas immolavit, in arena trucidans, inter subcubicularios gladiatores pugnum incautibus allegando mire ridens.*

Turnebus reads *radiarios* instead of *subcubicularios*; and understands it of those who had been dismissed, and could no longer be obliged to fight, except with files.

Salmasius reads *gladiatos*, and refers it to the emperor, who fought not only on the arena, and with files, or blunted instruments, but at home, with his servants and valets de chambre, and with sharps.

Lipsius will have nothing altered in the text: the *gladiatores cubiculorii*, he observes, were those who fought at private houses, during feasts, &c. Accordingly, Dion says expressly, that Commodus sometimes fought at home, and even killed some persons in such rencounters; but that, in public, he only fought with blunted weapons.

The *dimachæri*, who fought armed with two poniards, or swords; or with sword and dagger. Lipf. Saturn. lib. ii. cap. 13.

The *essedarii*, who fought in cars; called also, in an inscription lately discovered at Lyons, *equidarii*. Saturn. sern. lib. ii. cap. 13.

The *fiscales*, or *Cæsariani*, who belonged to the emperor's company; and who, being more robust and dexterous than the rest, were frequently called for; and therefore

therefore named alſo *pyllatitii*. Saturn. lib. ii. cap. 16. The other kinds were, the *hoplomachi*, *meridiani*, *myrmillones*, *ordinarii*, *pinnirapi*, *protocatorei*, *retiarii*, *rudiarii*, *samnites*, *ſecutores*, *ſmittatores*, and *Thraces*: which ſee deſcribed under MERIDIANI, RETIARII, SECUTORES, &c.

Some authors, and particularly Vigenere on Livy, rank the *obſequentes*, mentioned by Spartian, in his life of Marcus Aurelius, among the number of *gladiators*: Lipſius laughs at him, Saturn. lib. ii. cap. 10. and with ſome reaſon: the obſequentes properly were the troops which that emperor raiſed among the *gladiators*; or whom of *gladiators* he made ſoldiers.

GLADIATORS *war*, *bellum* GLADIATORIUM, or *Spartacum*, called alſo the *ſervile war*, was a war which the Romans ſuſtained about the year of their city 680. Spartacus, Crinus, Oenomaus, having eſcaped, with other *gladiators*, to the number of ſeventy-four, out of the place where they had been kept at Capua, gathered together a body of ſlaves, put themſelves at their head, rendered themſelves maſters of all Campania, and gained ſeveral victories over the Roman prætors. At length they were defeated, in the year 682, at the extremity of Italy; having, in vain, attempted to paſs over into Sicily.

This war proved very formidable to the Romans. Craſſus was not able to finiſh it: the great Pompey was forced to be ſent as general.

GLADIATOR, *vir.*, is a moſt valuable monument of ancient ſculpture, which is now preſerved in the palace of Chigni. This man, when he had received the mortal ſtroke, is particularly careful, *ut procumbat honeſte*, that he might fall honourably: he is ſeated in a reclining poſture on the ground, and has juſt ſtrength ſufficient to ſupport himſelf on his right arm; and in his expiring moments it is plainly ſeen that he does not abandon himſelf to grief and dejection, but is ſolicitous to maintain that firmneſs of aſpect, which the *gladiators* valued themſelves on preſerving in this ſeaſon of diſtreſs, and that attitude which they had learnt of the maſters of defence. He fears not death, nor ſeems to betray any tokens of fear by his countenance, nor to ſhed one tear: *quis mediocris gladiator ingemuit, quis vultum mutavit unquam, quis non modo ſtetit, verum etiam decubuit turpiter*, ſays Cicero, in that part of his Tuſculan, where he is deſcribing the aſtoniſhing firmneſs of theſe perſons. We ſee, in this inſtance, notwithſtanding his remaining ſtrength, that he has but a moment to live, and we view him with attention, that we may ſee him expire and fall: thus the ancients knew how to animate marble, and to give it almoſt every expreſſion of life. Encyclopedie.

GLADIOLUS, in *Botany*. See CORN-FLAG.

GLADIUS, *ſword*. *Jus* GLADII, or *right of the ſword*, is uſed, in our ancient Latin authors, and in the Norman laws, for ſupreme juriſdiction.

Camden, in Britannia, writes *Comitatus Flint pertinet ad* gladium *Ceſtriæ*: and Selden, Tit. of Honour, p. 640. *Curiam ſuam libram de omnibus placitis, &c. exceptis ad* gladium *ejus pertinentibus*.

And it is probably from hence, that, at the creation of an earl, he is *gladio cingitur*; to ſignify, that he had a juriſdiction over the county.

GLADIUS *piſcis*, in *Ichthyology*, a name uſed by many for the SWORD-FISH, called alſo the XIPHIAS.

GLADWIN. See IRIS.

GLAIR *of eggs*, is the ſame as the white of eggs, and is uſed by a varniſh for preſerving paintings. For this purpoſe it is beat to an unctuous conſiſtence, and commonly mixed with a little brandy or ſpirit of wine, to make it work more freely, and with a lump of ſugar to give it body and prevent its cracking: and then ſpread over the picture or painting with a brush.

GLAMA, in *Natural Hiſtory*, the name of a ſpecies of CAMEL, called alſo *elaphocamelus*, by many authors, and by many erroneouſly accounted a ſheep; its length from head to tail is about ſix feet; its height about four feet; its head, neck, and the general appearance of the upper part of the body, greatly reſemble the camel; and its upper lip is divided in the ſame manner as in that creature. Its parts of generation are alſo the ſame as in the camel; and it is deſtitute of the fore-teeth, and covers the cud like other animals that are ſo. It has no horns, and its feet are divided into two portions, which terminate in a ſort of claws, and are faſtened by a ſkin round the anterior part of the foot; the ſole of the foot is tender, and covered over only with a thick ſkin, as in the camel.

It has at the place where the breaſt joins to the belly a protuberance, like that which the camel and dromedary have in the ſame part, and in this animal Mathiolus obſerves that there is a continual diſcharge of a ſort of liquid excrement from it: but this has been ſuppoſed by ſome to be only accidental. It is a very tame animal, and fit for domeſtic uſes. It never offends any creature; but when provoked, revenges itſelf by diſcharging the contents of its ſtomach, by vomit, upon whatever injures it, and this it will do to a great diſtance.

The fleſh of this animal is eaten, and ſaid to be as good as mutton.

It is a native of Peru, and is of vaſt uſe to the inhabitants for carrying burdens; the weaker of them eaſily carry a hundred and fifty pounds weight, and the ſtronger two hundred and fifty. Ray's Syn. Quad. p. 143.

The guanaco of Peru may probably be the *glama* in its wild and ſavage ſtate: theſe are very timid and wary animals, for, whilſt they are feeding in great herds on the hills, one keeps watch, and on perceiving the approach of any one, nights, and thus gives the alarm to the herd, which run off with incredible ſpeed. They are killed for the ſake of their fleſh, and of their hair, which the Indians weave into cloth. Peumant's Synop. of Quad. p. 66.

GLAMA, in the *Old Writers of Medicine*, is ſometimes uſed to ſignify the ſordes of the eyes in ſuppuſions, and other diſorders attending them.

GLAND, GLANDULA, in *Anatomy*, a ſoft, ſpongy, lax kind of body; ſerving to ſeparate ſome particular HUMOUR from the maſs of BLOOD.

The ancients took the *glands* to be nothing more than a kind of pillow, or cuſhions, for the neighbouring parts to reſt on. Some of them, at length, began to fancy them ſponges, deſtined to receive and imbibe the ſuperfluous moiſture of the other parts.

Later phyſicians thought proper to aſſign them nobler and more important uſes. They conſidered them as ciſterns, which contained proper ferments, whereby the blood, upon its mixing therewith, was put into a fermentation; in the progreſs whereof it worked, or threw off certain of its parts, and ſent them away by excretory ducts.

The moderns, who allowed the *glands* to be the organs whereby the vital fluids are ſeparated for the uſes of the body, conſidered them as filtres, the pores whereof, being of different ſizes, would only admit of ſimilarly figured particles to paſs through them.

But the lateſt authors rather conceive the *glands* as ſieves, whoſe perforations, being of different ſizes, though of the ſame figure, only ſeparate ſuch particles whoſe diameters are leſs than their own.

The *glands*, to the eye, appear a ſort of whitiſh, membranous maſſes compoſed of an outer cover, or integument; within which a vaſcular plexus is contained. They are denominated from their reſemblance, in form, to acorns, which the Latins call *glandes*.

By diſſection, and the microſcope, they are found to be real plexuſes or pelotons, of veſſels, variouſly wound, and implicated among themſelves: but the modern anatomiſts Malpighi, Bellini, Warton, Nuck, Peyer, &c. have gone farther; and diſcovered them to be no more than continued convolutions of the capillary arteries.

Their formation appears to be thus. An artery, arriving at a certain part, is divided into an infinite number of exceedingly fine branches, or ramifications: theſe capillary branches are laid in various beds, and circumvolutions; and from the returns thereof ariſe new branches, or veſſels for veins; which a little farther unite, or terminate, in ſome larger branch or vein.

All theſe ramifications, both veins and arteries, are rolled up in a bundle; making numerous gyres, and circumvolutions: and from the various bends and angles, formed by both kinds, ariſe numerous other minute veſſels, which make the principal and moſt eſſential part of the *gland*.

The blood brought from the heart by the artery, into the glandular plexus, purſues all the turns and meanders in the arterial part thereof, till, arriving at the venous part, it is by it brought back again to the heart: in the mean time, during its progreſs through the arterial and venous folds, ſome part of it is abſorbed, or drained off, at the orifice of the tubules ariſing from the flexures thereof.

What is thus received into theſe, which we may call the *ſecretory ducts*, is commonly taken up by other tubules, ſpringing out of them: theſe, joining together, form a ſingle canal, which is called the *excretory duct*; which, paſſing out of the body of the *gland*, carries off the ſecreted matter into ſome proper receptacle deſtined to retain or receive it.

Though, ſometimes, the ſecretory veſſels themſelves terminate in a baſon or reſervoir; and depoſit their contents therein. Such is the general ſtructure, and office of the *glands*; which we ſhall farther illuſtrate, under SECRETION.

A *gland*, then, is a compoſition of divers kinds of veſſels;

fels; viz. an artery, and a vein; fecretory and excretory ducts: to which may be added, a nerve, which is found in every *gland*, diffufed through the whole fubftance thereof, to furnifh fpirits for promoting the fecretion; and a membrane, which fupports the convolutions of the vein and artery, accompanying them together through all the minuteft diviſions; to which add, lymphatics, which have been difcovered in feveral *glands*.

The fecretory tubes, however, are what we principally conſider as the organ of the *gland*: theſe, alone, ſometimes form the greateſt part of what is called a *gland*, or *glandulous body*.

The *glands* are liable to be ſo altered by accidents as to be fcarce known for what they really are; and their diſtemperatures are too often productive of the moſt miſchievous conſequences. The Paris memoirs give an account of a woman, who, attempting to lift a large weight, had a ſwelling that appeared the ſame day on the lower part of her arm, which continued increaſing in ſize for eighteen months. After this there appeared a hole in the inner part of the hand, from which there was diſcharged a quantity of matter daily, but yet the ſwelling continued to increaſe. At the end of two years ſhe conſented to have it laid open. There was very little matter diſcharged, the whole not amounting to more than two ſpoonfuls of a thick viſcous fluid; all the reſt of the tumor was ſolid, and contained about two hundred white bodies, of a roundiſh, but ſomewhat oblong figure, and not unaptly reſembling ſome of the kinds of kidney-beans. Theſe were covered with a ſolid membrane, and had no cavity within: and ſome of them had at one end a ſort of ſtalk, or pedicle, by which they ſeemed to have been faſtened to ſome other body. Theſe were the *glands* which had loſt their natural uſe, and were become hard, and what ſeemed a pedicle or ſtalk to ſome of them was their excretory duct which had not periſhed. Mem. Acad. Par. 1708.

The *glands* which have no particular ſecretory ducts, are called *glandulæ cavæ*, or *clauſæ*.

Dr. Quelmalius argues for theſe *glands* being deſigned to prepare nouriſhment for the other parts, from the obſervation that they decreaſe after birth to full growth, then continue in the ſame condition till old age comes on; after which they gradually ſhrivel. Select. Medic. Francfurt. tom. ii. vol. i. § 3.

M. Winſlow has diſcovered a kind of tomentum, or down, within their cavity, which he ſuppoſes to do the office of a ſtrainer, and to be that whereby ſuch a certain humour is ſeparated from the common maſs of blood. His ſyſtem will be explained, when we come to treat of SECRETION.

The down-veſſel being the grand organ of ſecretion, its ſtructure and application are diverſified, according to the different purpoſes nature has in view. Sometimes the liquor, ſtrained through it, trickles out, drop by drop, upon a membrane, to which one extremity of the veſſel is faſtened; as where the filtration is only intended for moiſtening and lubricating the part with that liquor: in which caſe, the down-veſſel is both ſecretory, and excretory; which is the moſt ſimple caſe. Such are thoſe innumerable *glands* ſpread through the greater part of the viſcera.

Sometimes a great number of theſe down-veſſels are ſpread over the inner ſurface of a little membranous cell, into which they all pour their liquor, which is diſcharged hence at a little aperture in the cell. Such are the ſolitary *glands* of the inteſtines, which appear like ſo many little ſeparate grains.

Sometimes a veſſel is bent, and has only down in the firſt part thereof, which alone is ſecretory, and the reſt excretory, pouring the liquor into ſome other common cavity. Such are the *glands* that compoſe a calf's kidney.

The ſecretory veſſels are ſometimes of a very great length, notwithſtanding that they take up but little room; being wound over themſelves, again and again, ſometimes in a ſingle peloton, or knot: and ſometimes in ſeveral, inclofed in a common membrane.

The *glands* are of ſeveral kinds, in reſpect to their form, ſtructure, office, and uſe: authors uſually divide them into *conglobate* and *conglomerate*.

GLANDS, *ſimple*, or *conglobate*, are thoſe conſiſting of one continuous maſs, with an uniform ſurface. Such are ſubcutaneous *glands*.

A conglobate *gland* is, more ſtrictly, a little ſmooth body, wrapped up in a fine double ſkin, by which it is ſeparated from all the other parts; only admitting an artery and nerve to paſs in, and a vein and excretory duct to go out.

Theſe *glands* either diſcharge their ſecreted humour into the chyle, or venous blood; or elſe it tranſpires through the pores of the ſkin, or the coats of the looſer membranes found in moſt parts of the body.

Of the conglobate kind are the *glands* in the cortical part of the brain, in which the animal ſpirits are ſuppoſed to be ſecreted: ſuch, alſo, are the labial *glands* and the teſtes. See LYMPHATICS.

GLANDS, *conglomerate*, or *compound*, is an irregular aſſemblage of ſeveral ſimple *glands* tied together, and wrapped up under one common membrane. Such are the maxillary glands, &c.

The humours ſecreted in theſe *glands* are ſometimes diſcharged at a common excretory duct, formed of an union of the excretory ducts of all the particular ones: this is the caſe in the pancreas, and parotides.

Sometimes the ducts, uniting, form ſeveral tubes, only communicating with each other by croſs canals; as in thoſe of the breaſts.

Some again, have ſeveral excretory tubes, without any communication together: as the glandulæ lacrymales, and proſtatæ.

Others have their ſeveral excretory ducts inſerted into a common canal, which opens, at laſt, into ſome of the greater cavities: as the ſalival *glands*, inteſtinal *glands*, &c.

Laſtly, in others, each *gland* has its own excretory duct, through which it tranſmits its liquor into a common baſon: ſuch are thoſe of the kidneys.

Some ſuppoſe and endeavour to prove the neceſſity of veſicles to the conglomerate *glands*, in order to receive all the different particles required in the compoſition of ſecerned liquors, which muſt be conveyed in different ſeries of veſſels, to be intimately blended in the veſicle, which will be conſiderably aſſiſted by the ſyſtole and diaſtole, which it is ſuppoſed the veſicle undergoes. See Acad. Bonon. Com. p. 336.

The *glands* are again divided into *vaſcular*, and *veſicular*.

GLANDS, *vaſcular*, are only cluſters of little veſſels, which, uniting together, form the canal, or excretory duct, through which the ſecreted juice is diſcharged.

GLANDS, *veſicular*, are aſſemblages of veſicular communicating with each other, and all terminating in two or three large veſſels; by a prolongation whereof, the excretory duct is formed.

The *glands*, again, are diviſed into the *adventitious*, and the *perpetual*, or *natural*.

GLANDS, *adventitious*, are thoſe kernels ariſing occaſionally under the arm-pits, on the neck, &c. Such are the ſtrumæ, and the tumors found on the larynx, and middle of the trachea.

GLANDS, *perpetual*, or *natural*, are of two kinds; conglobate, and conglomerate, as above deſcribed.

GLANDS of the *arteria aſperæ*. See ASPERA *Arteria*.

GLANDS, *axillary*, are thoſe ſituated in the AXILLA, or arm-pit. See HIRCUS.

GLANDS of the *Breaſt*. See BREAST.

GLANDS, *bronchial*. See BRONCHIAL.

GLANDS, *buccal*. See BUCCALES.

GLANDS, *ceruminous*, are thoſe which ſerve to ſeparate the ear-wax, or CERUMEN. See EAR.

GLANDS, *ciliary*. See CILIA.

GLANDS, *cyſtic* and *hepatic*. See LIVER and BILE.

GLAND, *dorſal*, is found in the thorax, about the fifth vertebra of the back, adhering to the poſterior part of the œſophagus. In different ſubjects it is of various ſizes: but it is commonly about the ſize of an almond; though it is ſometimes ſo ſmall as not to be found without great difficulty. Two *glands* are ſometimes ſeen in this part. The *dorſal gland* has been deſcribed by Veſalius and other ancient anatomiſts. Some have ſuppoſed that this *gland* ſerves to ſecrete a fluid to aſſiſt digeſtion, and others that it diſcharges a mucous fluid into the cavity of the œſophagus.

GLANDS, *inguinal*, are ſituated on each ſide in the groin, near the crural veſſels, and, in various diſeaſes, are apt to become tumid and inflamed. Abſceſſes are often formed in theſe *glands*.

GLANDS, *inteſtinal*. See INTESTINES.

GLANDS, *jugular*. See JUGULAR.

GLANDS, *labial*. See LIPS.

GLANDS, *lachrymal*. See LACHRYMAL.

GLANDS, *lumbal*, *glandulæ lumbares*, are three *glands* thus called by Bartholine, as lying on the loins.

The two largeſt lie upon one another, betwixt the deſcending cava and aorta, in the angle made by the emulgents with the cava; the third, and ſmalleſt, ſtands over the former, under the appendices of the diaphragm; they communicate, and are connected together by ſmall lacteal veſſels. Bartholine concluded them to ſerve as a common receptacle of the chyle; but Dr. Wharton's opinion is more probable, viz. that they ſupply the place of thoſe larger *glands* found in the meſentery of brutes.

GLANDS, *lymphatic*. See LYMPHATICS.

GLANDS, *maxillary*. See MAXILLARY.

GLANDS, *meſenteric*. See MESENTERY.

GLANDS, *miliary*, *glandulæ miliares*. See MILIARY *glands*.

GLANDS,

GLANDS, *molar*. See MOLAR.

GLANDS, *mucilaginous*. See MUCILAGINOUS *glands*.

GLANDS, *mucous, glandulæ mucosæ*. See MUCOUS *glands*.

GLANDS, *myrtiform*, are contractions of the hymen, broke by the firſt act of venery. See CARUNCULÆ *myrtiformes* and HYMEN.

GLANDS, *Nuckian*. See NUCKIANA.

GLANDS, *odoriferous, glandulæ odoriferæ*, are certain ſmall *glands*, diſcovered by Dr. Tyſon, in that part of the PENIS where the prepuce is contiguous to the balanus.

He gave them the name from the briſk ſcent which their ſeparated liquor emits. In ſuch perſons as have the prepuce longer than ordinary, theſe are not only more in number, but larger, and ſeparate a greater quantity of juice, which, lodging there, often grows rancid, and corrupts the *glands*. Theſe *glands* are very conſpicuous in moſt quadrupeds, eſpecially in dogs and the boar.

GLANDS *of the œſophagus*. See OESOPHAGUS.

GLANDS, *palatine*. See PALATE.

GLANDS, *parotid*. See PAROTIDES.

GLAND, *pineal, glandula pinealis*. See PINEAL *gland* and CONARION.

GLAND, *pituitary, glandula pituitaria*. See PITUITARY *gland*.

GLANDS, *renal, glandulæ renales*, called alſo *capſulæ atrabilares*, are two *glands*, firſt diſcovered by Euſtachius, between the aorta and the kidneys, a little above the emulgent veſſels, though their ſituation and figure are varied; in ſome they are round, in others ſquare, triangular, &c. The right is uſually bigger than the left, and each about the ſize of a hen's egg: they are incloſed in fat.

Their uſe is not certainly known: it is ſuppoſed to be to ſeparate a liquor from the arterial blood, before it goes to the kidneys. See CAPSULÆ *atrabilares*.

Mr. Du Vernoy remarks the *glandulæ renales* to be very variable in their magnitude, figure, &c. but that they are always contiguous, and firmly connected to the kidneys. In ſome foetuſes they appear ſolid, without any cavity; in others, they are diſtended with thin blood; in adults, they are always flat: they are readily diſtended, by blowing air into them by the vein. When the *glands* are opened, and quickſilver is injected, a great many ducts are ſeen, at which the mercury runs out. Two arteries and a vein belong to each *gland*, and a great many ducts, like rays, make a circle round it. An artery, ariſing from the aorta, is ſent down from the lower edge of the *gland* to the teſtes of men, and ovaria of women, which Valſalva miſtook for ducts. Comment. Acad. Petrop. tome v. See RENES *ſuccenturiati*.

GLANDS, *ſalival*. See SALIVA.

GLANDS, *ſebaceous, glandulæ ſebaceæ*, are a number of *glands* placed under the ſkin of the auricle of the ear, firſt diſcover by Valſalva, and thus denominated, becauſe they ſeparate a greaſy matter, like ſebum, or tallow.

This ſebum, he aſſerts, being carried to the ſurface of the ſkin, turns it into a ſcaly ſubſtance, not unlike bran. There are many *glands*, of different kinds, which bear this name from their uſe.

GLANDS, *ſplenic*. See SPLEEN.

GLANDS, *ſublingual*. See SUBLINGUAL.

GLANDS, *thyroid*. See THYROIDES.

GLANDS, *diſeaſes of*. See CANCER and SCIRRHUS.

GLANDES *terræ*, a name uſed by ſome authors for the tuberous root of a plant of the LATHYRUS kind, called the *lathyrus repens tuberoſus*.

GLANDERS, a filthy diſeaſe in a horſe, conſiſting in a corrupt ſlimy matter, running from the noſe, of a different colour according to the degree of the malignity, or as the infection has been of a ſhorter or longer continuance; being white, yellow, green, or black, ſometimes tinged with blood.

Authors aſcribe it to various cauſes: ſome to infection; ſome to a diſorder of the lungs; others to the ſpleen; ſome to the liver; and others to the brain. *After* it has been of ſo long ſtanding, that the matter is of a blackiſh colour, which is uſually in its laſt ſtage, they ſuppoſe it to come from the ſpine; and hence they call it the *mourning of the chine*.

Kernels and knots are uſually felt under the caul in this diſorder; and as theſe grow bigger and more inflamed, ſo the *glanders* increaſe more.

M. La Foſſe, farrier to the king of France, has lately taken great pains, by repeated diſſections, to diſcover the ſource and cauſe of this diſorder, and to aſcertain the proper and effectual method of cure. He has diſtinguiſhed ſeven different kinds of *glanders*, four of which are incurable. The firſt proceeds from ulcerated lungs, the purulent matter of which comes up the trachea, and is diſcharged through the noſtrils, like a whitiſh liquor, appearing ſometimes in lumps and grumes: the ſecond is a waſting humour, that uſually ſeizes horſes at the deceaſe of a diſeaſe cauſed by too hard labour, and proceeds from the lungs: the third is a malignant diſcharge, which ſometimes attends the STRANGLES, falls upon the lungs, and is diſcharged at the noſtrils: the fourth is when an acrimonious humour in the PAROTY ſeizes thoſe parts: the fifth ariſes from a horſe's taking cold: the ſixth is a diſcharge from the ſtrangles, which ſometimes vents itſelf at the noſtrils: the ſeventh, or real *glanders*, is that above deſcribed.

M. La Foſſe, after examining, by diſſection, the carcaſes of glandered horſes, and making a ſtrict ſcrutiny into the ſtate of the viſcera, aſſiſted in his enquiry by ingenious anatomiſts for the ſpace of ten years, affirms this diſeaſe to be altogether local, and that the true ſeat of it is in the pituitary membrane which lines the partition along the inſide of the noſe, the maxillary ſinuſes or cavities of the cheek-bones on each ſide of the noſe, and the frontal ſinuſes or cavities above the orbits of the eyes; that the viſcera, as the liver, lungs, &c. of glandered horſes are, in general, very ſound; and, therefore, that the ſeat of the diſorder is not in thoſe parts, as many authors have aſſerted.

He found theſe cavities more or leſs filled with a viſcous ſlimy matter; the membrane, which lines both them and the noſtrils, inflamed, thickened, and corroded with ſordid ulcers, which, in ſome caſes, had eat into the bones. He obſerves, that, when glandered horſes diſcharge matter from both noſtrils, both ſides of the membrane and cavities were affected; but when they ran at one noſtril only, that ſide only was found diſtempered: and if one gland only was affected, the horſe diſcharged from one noſtril only; but if both were affected, the diſcharge was from both. It has been obſerved, that the *glanders* in horſes very much reſembles a diſorder in men, called the OZENA.

In this diſeaſe, if the matter ſticks to the inſide of the noſtrils, like glue or ſtiff paſte; if the inſide of the noſe is raw, and appears of a livid or leaden hue, and the matter becomes bloody, fœtid, and of an aſh colour; theſe ſymptoms are very unfavourable: but when only a limpid fluid is firſt diſcharged, and afterwards a whitiſh matter, the gland under the jaw does not much increaſe, and the *diſorder* has been of no long continuance, a ſpeedy cure may be expected. The cure of this milder kind of *glanders* may firſt be attempted by injections and fumigations. When theſe latter ſymptoms appear, the horſe ſhould firſt be bled, and treated as in the common diſorder of cold; and then, let an emollient injection, prepared with a decoction of linſeed, marſh-mallows, elder, chamomile flowers, and honey of roſes, or ſuch like, be thrown up as far as poſſible with a ſtrong ſyringe, and repeated three times a day: if the running is not leſſened or removed in a fortnight by theſe means, a reſtringent injection may be prepared with tincture of roſes, lime-water, &c. and the noſtrils fumigated with the powders of frankincenſe, maſtic, amber, and cinnabar, burnt on an iron heated for that purpoſe, the fumes of which may eaſily be conveyed through a tube into the noſtrils. When the diſeaſe is inveterate, recourſe muſt be had to the operation of trepanning, which M. La Foſſe performed on three horſes, two of which diſcharged from one noſtril only, and the third from both: he trepanned the two firſt on that ſide of the head which was affected, and the other on both ſides, and found that the wound and perforation filled up with good fleſh in twenty-ſix days, and the horſes ſuffered no inconvenience from the operation. The method of performing this operation will be underſtood by means of *fig.* 22. *Tab. Miſcellany*, and the following explication: B, B, are two lines repreſenting the bounds of the cerebellum, or back part of the brain, which commences from the line D. C C is a line, where the ſuperior part of the ſinus frontalis commences, together with a view of the bottom of the ſinus, terminating between the lines D and E, where appears a ſubſtance in the form of a pear, which is the os ethmoides, or ſieve-like bone through which the olfactory nerves paſs, communicating ſenſibility to the pituitary membrane. E repreſents the beginning of the maxillary ſinus, terminating at M: the ſhaded ſpace between theſe lines repreſents the great cavities. F is a bony partition, ſeparating this ſinus into two parts that have no communication; of which partitions there are ſometimes two, repreſented by F and G. Some horſes have neither of theſe. N ſhews the place of the cornets or horns; O, the redoubtings; P, their middle part; Q_2 the lower part of them: and M, the bony pipe or canal which guards the maxillary nerve: A A is the ſeptum narium, dividing the noſe from top to bottom, and ſeparating the two noſtrils; L ſhews the place where the trepan ſhould be applied, when there is reaſon to apprehend that the *glanders* is ſpread into the frontal ſinus; E is the place where it ſhould be applied

to

to cleanse the maxillary sinus, though the round spot between D and E is preferable, because one orifice in this place will serve to wash all the parts, both above and below, with one injection. H shews the place where another perforation should be made, as a drain for discharging the foul matter washed away by the injection: and this hole, kept open by a hollow leaden pipe, would, in all recent cases, be sufficient. I represents the injection thrown in by the syringe, which flows out by the orifice and the nostril K; and, during this part of the operation, the nostrils should be held close. If there should be two boars in the maxillary sinus, it is absolutely necessary to pierce through both, with a thillet or sharp-pointed trocar, as in the figure. The trepan should be directed towards the interior part of the nose, to prevent its being obstructed by the roots of the teeth. E is the trepan, S the handle which turns it, and T the saw-part to be applied to the bone. The surgeon's trephine will answer the purpose for this operation; but before the instrument is applied, a circular piece of the skin, of about the size of half a crown, should be first cut off with the membrane which covers the bone. The syringe should be large enough to contain half a pint of injection. The injection first used should be of a detersive nature, as a decoction of birth-wort, gentian, and centaury, to a quart of which may be added two ounces of Egyptiacum and tincture of myrrh; and when the discharge abates, and the matter becomes of a thick consistence and white colour, this injection may be changed for barley-water, honey of roses, and tincture of myrrh; and for completing the cure, Bates's alum-water, or a solution of colcothar, vitriol, lapis medicamentosus, and such like, in lime water, will serve to dry up the moisture, and to restore the tone of the relaxed glands. For this purpose Dr. Bracken recommends the following mixture: take of alum and white vitriol, powdered, of each four ounces; calcine them in a crucible; when cold, powder the calx, and mix it with a gallon of lime-water and a quart of vinegar, and decant the mixture clear for use. The perforations that are made in this operation should be kept open, after the use of the injection, by fitting to the upper one a piece of cork waxed over, and a hollow leaden tent to the lower, through which there will be a constant drain of matter from the sinuses; and both may be secured by a proper bandage. The growth of the flesh should be also checked by rubbing with caustic medicines, or applying the actual cautery. The cure will be expedited, by giving every day a quart or three pints of a strong decoction of guaiacum chips, by purging at proper intervals, and putting a towel into the horse's chest: and if these fail, mercurials may be administered with the physic, and the alterative powders with lime-water may be given and continued for some time.

The following remedy is said to have succeeded, in fifty cases out of fixty, for curing the *glanders*, without trepanning. Keep the horse a day or two with small quantities of choice hay, and scalded bran; then blow up his nostrils as much assafœtida, in fine powder, as will lie on a six-pence, evening and morning, giving him for drink small lime-water, during four or five days: then boil two ounces of elecampane roots in a quart of milk, till they mix, and give it once a day during three or four days more; then boil two handfuls of the white moss that grows on oaken pales, in two quarts of milk, till one is consumed; strain it and squeeze the moss and give the milk luke warm: repeat this for four or five days. About an hour after the horse has had his drink each day, take a piece of sweet butter, about the size of an egg, and about half an ounce of brimstone finely powdered, and work them well together; then take two clean goose feathers, as long as they can be procured, and make a hole in each of the quill ends, in which fasten two long threads; then anoint the feathers well with the mixture, and roll them in dry flower of brimstone: open the horse's nostrils, and thrust the feathers up into his head, fastening the threads to the top of his head, to prevent their dropping out: ride him an hour or two morning and evening, and let him stand half an hour after he returns to the stable before the feathers are taken out: pursue this course eight or nine days, bathing his head with camphorated spirits of wine, and afterwards confining his head over a tub of hot grains, that he may breathe the steam. A rowel may prevent a relapse.

GLANDULA, in *Anatomy*, the same as GLAND.

The word is a diminutive of the Latin *glans*, *quæ*; and is here used on account of some external resemblance between the glands of the body and the fruit of the oak.

GLANDULA *Gaudinii*, among *Surgeons*, is a tumor resembling a gland; soft, fingle, moveable, with roots, and separate from the adjacent parts.

GLANDULE, in *English*, fignifies a little gland. Thus the amygdalæ, or almonds of the ears, are by some called *glandulæ*.

GLANDULOUS, or GLANDULAR, something compofed of glands, or that abounds with glands.

The BREASTS are *glandulous* bodies. The cortical fubftance of the brain is commonly reputed to be *glandulous*; though Ruyfch, from the difcoveries made by his admirable injections, holds, that there is no fuch thing as a gland therein.

The ancients diftinguifhed a particular kind of flefh, which they called *caro glandulofa*, or *glandulous* FLESH.

GLANDULOUS *body*, *glandulofum corpus*, more particularly denotes the PROSTATA.

GLANDULOUS *root*, among *Botanifts*, fuch tuberofe roots as are faftened together in large numbers by fmall fibres or threads.

GLANIS, in *Ichthyology*, the name of a fifh, called in Engliſh the ſheat-fiſh, and in Latin SILURUS.

GLANS, *Acorn*, in *Natural Hiſtory*, a fruit contained within a fmooth but hard bark, including a fingle feed; its hind-part being covered with a kind of cup, and the fore-part bare. See ACORN and OAK.

GLANS, in *Anatomy*, the tip or button of the PENIS, or that part covered with the prepuce, called alſo *balanus*. See *Tab. Anat.* (*Splanch.*) *fig.* 10. *let. d. fig.* 15. *let. a.*

The *glans* is only a dilatation of the extremity of the fpongeous fubftance of the urethra, which is here bunched, and turned back to the two conical tips of the corpora cavernoſa, which terminate therein.

The extremity of the prepuce is apt to grow ſo ſtreight in old men, that they cannot bare the *glans*; perhaps through the defect of frequent erections.

We read of a *glans penis* regenerated after amputation, in the Medical Eſſ. Edinb. vol. v. art. 35.

GLANS is alſo uſed to denote the tip or extremity of the CLITORIS, from its reſemblance, both in form and uſe, to that of the penis. See *Tab. Anat.* (*Splanch.*) *fig.* 13. *let. c.*

The principal difference conſiſts in this, that it is not perforated. This *glans* is alſo covered with a prepuſium, formed of the inner membrane of the labia.

GLANS *marina*, in *Natural Hiſtory*, a name given to a genus of ſhell-fiſh, more uſually called BALANUS, and in Engliſh the centre-ſhell.

GLANS *lenticulifera*, in *Natural Hiſtory*, a name given by Geſtner, and ſome other writers, to a kind of figured foſſil, found uſually among the trochitæ and entrochi, and evidently appearing to have in ſome manner belonged to them. All the writers, who have themſelves examined the places where the trochitæ are found, have mentioned theſe under the names of *glandes trochitiferæ*, others under leſs determinate ones. Agricola calls them *lapides informes*; and Liſter, after him, *rude ſtones* having impreſſions of the entrochi. See farther Philoſ. Tranſ. N° 100.

GLANUS, or GLANIS, in *Ichthyology*, a name given by Pliny, and many other of the old writers, to that ſpecies of the ſiluros which we in England call the ſheat-fiſh, the *glanis* and SILURUS of authors, diſtinguiſhed by Artedi by the name of the ſiluros with four boards on the chin.

GLAREANA, in *Ornithology*, the name of a bird deſcribed by Geſner from the figure, and ſuſpected to be no way different from the SPIPOLETTA, called tordino by the Venetians, a kind of lark.

GLASS, *vitrum*, a tranſparent, ſolid, brittle, factitious body, produced of a ſalt and ſand, or ſtone, by the action of fire.

The word is formed of the Latin *glaſtum*, a plant called by the Greeks, *ἰσατις*; by the Romans, *vitrum*; by the ancient Britons, *guadum*; by the Engliſh, WOAD. We find frequent mention of this plant in ancient writers, particularly Cæſar, Vitruvius, Pliny, &c. who relate, that the ancient Britons painted or dyed their bodies with glaſtum, guadum, vitrum, &c. i. e. with the blue colour procured from this plant. And hence the factitious matter we are ſpeaking of, came to be called *glaſs*, as having always ſomewhat of this bluiſhneſs in it.

The chemiſts hold that there is no body but may be vitrified, i. e. converted into *glaſs*. By intenſe heat, even GOLD itſelf gives way to the ſun's rays collected in a BURNING-*glaſs*, and becomes *glaſs*.

Add, that as *glaſs* is the effect or fruit of fire, ſo it is the laſt effect of that element; all the chemiſt's art, and all the force of fire not being able to carry the change of any natural body beyond its VITRIFICATION.

GLASS, *nature and characters of*. Naturaliſts are divided in what claſs of bodies to rank *glaſs*. Agricola conſiders it as a concrete juice; Bellovacenſis, as a ſtone; Fallopius ranks it among the *ſucci mineralia*; and the workmen, when in fuſion, call it metal: but Dr. Merret, with reaſon, ſets aſide all theſe opinions; from this conſideration, that all the forementioned bodies are natural concretes; whereas *glaſs* is a compound made by art, and is never found in the earth as the others.

Fallopius,

Fallopius, indeed, contends, that *glass* is no more artificial than a metal, and that they are both equally extracted or educed from other bodies; the one from sand, the other from its ore. He adds, that though salts or ashes be added to sand for the making of *glass*, yet it is false that they contribute to the composition of *glass*; their use, according to him, being only for the better extracting of the *glass* from the mineral stone

This Dr. Merret easily confutes: for if *glass* were extracted from stones or sand only, the weight of the metal must be much less than that of the stones alone; whereas it is, in reality, much greater, a hundred weight of sand sufficing for one hundred and fifty of *glass*.

In effect, the ashes contribute a deal of salt to the composition of *glass*. Accordingly, in pieces of old *glass* one may sometimes pick out grains of salt, easily discoverable to the taste; beside that the finest *glass*, standing long in a subterraneous place, will moulder or resolve into its first ingredients, salt and sand, by the decay of the union thereof: whence it appears, that the salt remains in the *glass* in specie. To which may be added that experiment of Van Helmont: "Melt *glass*-dust with "fandiver, and set them in a moist place, and the *glass* "will resolve into water; pour on aqua regia, enough "to saturate the fandiver, and the sand will precipitate "to the bottom in the same quantity and weight as was "first used." Helm. cap. De Terra.

Here, then, is a true analysis of *glass*, or a solution into its first principle or ingredients, the salt being imbibed by the fandiver and aqua regia. Merret. Not. in Ant. Neri De Art. Vitrar.

The learned and curious author just mentioned gives us the following characters or properties of *glass*, whereby it is distinguished from all other bodies, viz. 1. That it is an artificial concrete of salt and sand, or stones. 2. Fusible by a strong fire. 3. When fused, tenacious and coherent. 4. It does not waste or consume in the fire. 5. When melted, it cleaves to iron. 6. Ductile, when red-hot, and fashionable into any form, but not malleable; and capable of being blown into a hollowness, which no mineral is. 7. Frangible, when thin, without annealing. 8. Friable when cold. 9. Always diaphanous, whether hot or cold. 10. Flexible and elastic. 11. Dissoluble by cold and moisture. 12. Only capable of being graven, or cut with a diamond or other hard stones, and emery. 13. Receives any colour or dye both externally and internally. 14. Not dissolvable by aqua fortis, aqua regia, or mercury. 15. Neither acid juices, nor any other matter, extract either colour, taste, or any other quality, from it. 16. It admits of polishing. 17. Neither loses of weight nor substance, by the longest and most frequent use. 18. Gives fusion to other metals, and softens them. 19. The most pliable thing in the world, and that which best retains the fashion given it. 20. Not capable of being calcined. 21. An open *glass*, filled with water in the summer-time, will gather drops of water on the outside, just so far as the water on the inside reaches; and a man's breath blown upon it will manifestly moisten it. 22. Little glass balls, filled with water, mercury, or other liquor, and thrown into the fire, as also drops of green *glass* broken, fly asunder with a loud noise. 23. Neither wine, beer, nor any other liquor, will make it musty, nor change its colour, nor rust it. 24. It may be cemented as stones and metals. 25. A drinking-*glass*, partly filled with water, and rubbed on the brim with a wet finger, yields musical notes, higher or lower, as the *glass* is more or less full; and this makes the liquor fritk and leap.

GLASS, *ductility of.* See DUCTILITY.

GLASS, *origin and history of.* De Neri will have *glass* as ancient as Job; for that writer, chap. xxviii. ver. 17. speaking of wisdom, says, Gold and *glass* shall not be equalled to it.

This, we are to observe, is the reading of the Septuagint, Vulgate Latin, St. Jerom, Pineda, &c. for in the English version, instead of *glass*, we read *crystal*; and the same is done in the Chaldee, Arias Montanus, and the king of Spain's edition. In other versions, &c. it is read *stone*; in others, *beryl*: in the Italian, Spanish, French, High and Low Dutch, &c. *diamond*; in others, *carbuncle*; and in the Targum, *looking-glass*.

In effect, the original word is נקוכות, which is derived from the root נקה, *to purify, cleanse, shine, be white, transparent*: and the same word, Exod. xxx. 34. is applied to frankincense; and rendered in the Septuagint, *pellucid*. Hence the reason of so many different renderings; for the word signifying *beautiful* and *transparent*, in the general, the translators were at liberty to apply it to whatever was valuable and transparent.

Most authors will have Aristophanes to be the first author who mentions *glass*: that poet, in his comedy called the Clouds, scene i. act ii. uses the word ὑαλοῦν, which is now ordinarily rendered *glass*. He there introduces Strepsiades, teaching Socrates a new way to pay old debts, viz. "by placing a fair transparent stone, "fold by the druggists, from which the fire is struck, "between the sun and the writing, and so melting away "the letters thereof." This stone Socrates calls λιθον, which the scholiast on Aristophanes derives from ὕω, *to rain*, from the likeness it bears to ice, which is rain, or water congealed; though, it must be owned, the word λιθος is ambiguous, and signifies *crystal* as well as *glass*: and Gorræus observes, that the ancients had a kind of yellow amber, transparent as *glass*, called by some λιθος.

Aristotle has two problems upon *glass*: the first, Why we see through it? The second, Why it is not malleable? If these problems be Aristotle's, which the learned doubt very much, this would probably be the earliest testimony in favour of the antiquity of *glass*; but the first author, who makes unquestionable mention of this matter, is Alexander Aphrodiseus, who uses it in a simile: "As the floridness of a colour is seen through "*glass*," &c.

After him the word occurs commonly enough: Lucian mentions large drinking-*glasses*; and Plutarch, in his Symposiacon, says, that the fire of tamarisk-wood is the fittest for the making of *glass*.

Among the Latin writers, Lucretius is the first that takes notice of *glass*. *Nisi recta foramina transmit, Quale fuit vitri.* Dr. Merret, however, adds, that *glass* could not be unknown to the ancients, but that it must needs be as ancient as pottery itself; or the art of making bricks; for scarcely can a kiln of bricks be burnt, or a batch of pottery ware be made, but some of the bricks and ware will be at least imperfectly turned to *glass*.

Hence, Ferrarius Impertus, lib. xxv. cap. 7. "*Glass*, "like the common kind, is found under ground, in "places where great fires have been. Other *glasses* are "found in round clods, like fire-stone, some brittle, "others firm, &c. This fossil *glass* is wrought by the "Americans, and used instead of iron."

And no doubt but vitrifications were more common in the ancient bricks than they are in ours; as they tempered their earth two years together, and burnt them better.

Pliny relates the manner of the discovery of *glass*. It was found, according to that author, by accident, in Syria, at the mouth of the river Belus, by certain merchants driven thither by the fortune of the sea. Being obliged to live there, and dress their victuals by making a fire on the ground, and there being store of the plant kali upon the spot, this herb being burnt to ashes, and the sand or stones of the place accidentally mixed with it, a vitrification was undesignedly made; from whence the hint was taken, and easily improved.

Indeed, how old soever *glass* may be, the art of making and working it appears of no great antiquity. The first place mentioned for the making hereof, is Sidon in Syria, which was famous for *glass* and *glass*-houses, as observed by Pliny, lib. xxxvi. cap. 26. § 66. Mr. Nixon, in his observations on a plate of *glass*, found at Herculaneum, which was destroyed A. D. 80, on which occasion Pliny lost his life, offers several probable conjectures as to the uses to which such plates might be applied.

Such plates, he supposes, might serve for *specula*, or looking-*glasses*; for Pliny, in speaking of Sidon, adds, *fecundem etiam specula excogitaverat*: the perfection of images from these ancient specula being effected by bestowing them behind, or tinging them through with some dark colour. Another use in which they might be employed, was for adorning the walls of their apartments, by way of wainscot, to which Pliny is supposed to refer by his *vitreæ cameræ*, lib. xxxvi. cap. 25. § 64. Mr. Nixon farther conjectures, that these *glass* plates might be used for windows, as well as the lamina of *lapis* SPECULARIS and PHENGITES, which were improvements in luxury mentioned by Seneca, and introduced in his time, Ep. xc. However, there is no positive authority relating to the usage of *glass*-windows earlier than the close of the third century: *Manifestius est*, says Lactantius, *mentem esse, quæ per oculos ea quæ sunt opposita, transpiciat, quasi per fenestras lucentes vitro aut speculari lapide obductas.* De Opificio Dei, cap. 5. See Phil. Trans. vol. I. art. 80. p. 601. vol. iii. art. 23. p. 123.

The first time we hear of *glass* made among the Romans was in the time of Tiberius, when Pliny relates, that an artist had his house demolished for making *glass* malleable, or rather flexible; though Petronius Arbiter, and some others, assure us, that the emperor ordered the artist to be beheaded for his invention.

According to venerable Bede, artificers skilled in making *glass* were brought over into England, in the year 674,

by abbot Benedict, who were employed in glazing the church and monastery of Weremouth. According to others, they were firſt brought over by Wilfrid, biſhop of Worceſter, about the ſame time. Till this time the art of making *glaſs* was unknown in Britain; though *glaſs* windows did not begin to be uſed before the year 1180: till this period they were very ſcarce in private houſes, and conſidered as a kind of luxury, and as marks of great magnificence. Italy had them firſt, next France, from whence they came into England.

Venice, for many years, excelled all Europe in the fineneſs of its *glaſſes*: and in the thirteenth century, the Venetians were the only people that had the ſecret of making cryſtal looking-*glaſſes*. The great *glaſs*-works were at Murano, a village near the city, which furniſhed all Europe with the fineſt and largeſt *glaſſes*.

The *glaſs* manufacture was firſt begun in England in 1557: the finer ſort was made in the place called Cruſched Friars, in London; the fine flint *glaſs*, little inferior to that of Venice, was firſt made in the Savoyhouſe, in the Strand, London. This manufacture appears to have been much improved in 1635, when it was carried on with ſea-coal or pit-coal, inſtead of wood, and a monopoly was granted to ſir Robert Manſell, who was allowed to import the fine Venetian flint *glaſſes* for drinking, the art of making which was not brought to perfection before the reign of William III. But the firſt *glaſs* plates, for looking-*glaſſes*, and coach windows, were made in 1673, at Lambeth, by the encouragement of the duke of Buckingham; who, in 1670, introduced the manufacture of fine *glaſs* into England, by means of Venetian artiſts, with amazing ſucceſs. So that within a century paſt, the French and Engliſh have not only come up to, but even ſurpaſſed the Venetians, and we are now no longer ſupplied from abroad.

The French made a conſiderable improvement in the art of *glaſs*, by the invention of a method to caſt very large plates, till then unknown, and ſcarce practiſed yet by any but themſelves and the Engliſh.

That court applied itſelf with a laudable induſtry to cultivate and improve the *glaſs* manufacture. A company of *glaſs*-men was eſtabliſhed by letters patent: and it was provided by an arret, not only that the working in *glaſs* ſhould not derogate any thing from nobility, but even that none but nobles ſhould be allowed to work therein.

GLASS, *ingredients of*. The materials uſed in the compoſition of *glaſs*, we have obſerved, are ſalt and ſand, or elſe ſome kind of ſtone.

The ſalt is of the fixed kind, ſuch as will not evaporate with the moſt intenſe heat: the ſand or ſtone muſt be ſuch as will melt eaſily; this is what gives firmneſs and conſiſtence to the *glaſs*.

1. This ſalt is procured chiefly from a kind of aſhes, called POLVERINE, or *rochetta*, brought from the Levant, and particularly from Alexandria and Tripoly. The aſhes are thoſe of a vegetable, frequent in the country, commonly called KALI; ſometimes *kalli*, *kallu*, *calli*; by Geſner, *altuh*; by Lobel, *ſoda*; by Dodonæus, *ſalſola*; and by Camer, Gordonus, Fuſchius, &c. *anthyllis*. Dr. Merret calls it *Engliſh ſalt-wort*, from its ſaline taſte; and *glaſs-wood*, from the uſe made of its aſhes in making of *glaſs*.

Bauhin mentions ten ſpecies of this plant, whereof there are four uſed by the Alexandrians, &c. for the making of polverine and ſoap, viz. *kali genuinlatum*, *kali ſecundæ ſpeciei*, *kali Ægyptiacum*, and *kali ſpinoſum*.

The firſt and laſt our own coaſts afford, where they are called by the people *frog-graſs* and *ſea-graſs*; but they are of no uſe for making of *glaſs*: being laid on a hot iron, they fly off almoſt wholly in fumes, leaving almoſt no aſhes at all; whereas the kalia brought from the Levant, applied on the ſame iron, are ſoon converted almoſt wholly into polverine, i. e. very ſaline aſhes of a dark colour.

To get this ſalt from the polverine, they pulverize and ſift it very fine; then boil it in a braſs copper, with fair water and tartar, till a third part of the water is conſumed, taking care to ſtir it from time to time; then, filling up the copper with freſh water, they boil it a ſecond time, till half be conſumed: this done, they have a ley impregnated with ſalt. To get the ſalt from the ley, they boil them till the ſalt ſhoots at the top, which they ſcum off as it riſes into earthen pans, and thence into wooden vats to drain and dry.

When the ſalt is dry, they beat it groſly, and put it into a furnace, to dry it farther with a gentle heat. When it is made ſufficiently dry, they pound and ſift it very fine, and lay it by to make FRIT.

Note, Inſtead of the aſhes of the plant kali, thoſe of fern will alſo yield a ſalt which makes excellent *glaſs*, nothing inferior to that of polverine: the method of preparation is the ſame. Add, that the aſhes of the cods and ſtalks of beans, as alſo thoſe of coleworts, brambles-buſhs, millet ſtalks, ruſhes, cyperuſes, and many other plants, may be uſed for the like purpoſe, and after the ſame manner.

Pearl-aſhes form a leading flux in the manufacture of *glaſs*, and moſtly ſupply the place of the Levantine, the barilla of Spain, and many other kinds, which were formerly brought here for making both *glaſs* and ſoap. See PEARL-*aſhes*.

There are other fluxes uſed for different kinds of *glaſs*, and for various purpoſes, as calcined lead, nitre, ſea-ſalt, borax, arſenic, ſmiths clinkers, and woodaſhes, containing the earth and lixiviate ſalt as produced by incineration. With regard to theſe ſeveral fluxes, we may obſerve, in general, that the more calx of lead, or other metallic earth enters into the compoſition of any *glaſs*, ſo much the more fuſible, ſoft, coloured, and denſe this *glaſs* is, and reciprocally.

The colours given to *glaſs* by calxes of lead, are ſhades of yellow: on the other hand, *glaſſes* that contain only ſaline fluxes partake of the properties of ſalts; they are leſs heavy, leſs denſe, harder, whiter, more brilliant, and more brittle than the former; and *glaſſes* containing both ſaline and metallic fluxes, do alſo partake of the properties of both theſe ſubſtances. *Glaſſes* too ſaline are eaſily ſuſceptible of alteration by the action of air and water; eſpecially thoſe in which alkalies prevail; and theſe are alſo liable to be injured by acids. Thoſe that contain too much borax and arſenic, though at firſt they appear very beautiful, quickly tarniſh and become opake when expoſed to air. By attending to theſe properties of different fluxes, phlogiſtic or ſaline, the artiſt may know how to adjuſt the proportions of theſe to ſand, or powdered flints, for the various kinds of *glaſs*. If a *glaſs* be required that is denſe, fuſible, and not ſaline, one part and a half of red lead or litharge may be mixed with one part of ſand, and fuſed together: if equal parts of ſand and of calx of lead be employed, a *glaſs* ſomewhat leſs denſe and harder will be produced: if a *glaſs* be required of very little denſity, only ſaline fluxes muſt be employed. A *glaſs* of this kind may be compoſed of ſix parts of ſalt of tartar, or of pot-aſh, or of purified ſoda, mixed with eight parts of ſand or of flints; or of four parts of any of the above mentioned alkalies, mixed with two parts of nitre or of borax, and eight parts of vitrifiable earth. When a cryſtal *glaſs* is required, which ſhall be of an intermediate quality betwixt the metallic and ſaline *glaſſes*, it may be made from a mixture of one part of the above mentioned ſalts, one part of calx of lead, and two parts of ſand or other vitrifiable earth.

By varying the proportion of theſe ingredients, many different kinds of *glaſſes* may be produced, each of which may be good, if the quantity of each of the fluxes employed be proportionable to its vitrifying power. Dict. Chem. art. *Vitrification*.

2. For ſtone, the ſecond ingredient in *glaſs*. The beſt, we have obſerved, is that which will melt, is white, and tranſparent. This is found principally in Italy, being a ſort of ſtony ſubſtance, called *tarſo*: the next is *pureth*, or cuogola, a ſort of pebbles found at the bottoms of rivers, and gathered for the Venetian manufacture out of the river Po, which are ſaid not to be inferior in whiteneſs to alabaſter.

Indeed, nothing makes finer and clearer *glaſs* than common flint, diſtinguiſhed by this uſe for their clear, tranſparent, black colour: but the charge of preparing it deters the *glaſs*-men from uſing it. The preparation neceſſary for ſtone is to calcine, powder, and ſierce it.

Ant. Neri obſerves, that all white tranſparent ſtones, which will not burn to lime, are fit to make *glaſs*; and that all ſtones which will ſtrike fire with ſteel, are capable of being employed in making of *glaſs*. But this latter rule, Dr. Merret obſerves, does not hold univerſally.

Where proper ſtone cannot be had, ſand is uſed; and it is now almoſt the only kind of ſubſtance employed in the Britiſh manufactures of *glaſs*. The beſt for this purpoſe is that which is white, ſmall, and ſhining; examined by the microſcope, it appears to be ſmall fragments of rock cryſtal. For green *glaſs*, that which is of a ſoft texture, and more gritty; it is to be well waſhed, which is all the preparation it needs. Our glaſs-houſes are ſupplied with white ſand for their cryſtal *glaſſes* from Alum-bay in Norfolk, and Maidſtone in Kent: and with the coarſer for green *glaſs*, from Woolwich.

Some mention a third ingredient in *glaſs*; viz. MANGANESE, or MAGNESIA, or *ſyderos*, a kind of pſeudo-loadſtone, dug up in Germany, Italy, and even in Mendip hills in Somerſetſhire. But the proportion hereof to the other is very inconſiderable; beſides that it is not uſed in all *glaſs*. Its office is to purge off the natural green colour and give it ſome other tincture required.

For this purpose it ſhould be choſen of a deep colour, and free from ſpecks of a metalline appearance, or a lighter caſt; magneſia requires to be well calcined in a hot furnace, and then to undergo a thorough leviga-tion. The effect of magneſia in deſtroying the colours of *glaſs*, and hence called the ſoap of *glaſs*, is accounted for by M. Montamy, in his Traite des Couleurs pour la Peinture en Emaile, in the following manner: the magneſia de-ſtroys the green, olive, and blue colours of *glaſs*, by adding to them a purple tinge, and by the mixture produc-ing a blackiſh brown colour; and, as blackneſs is cauſed merely by an abſorption of the rays of light, the blackiſh colour given to the *glaſs* by the mixture of colours, pre-vents the reflection of ſo many rays, and thus renders the *glaſs* leſs coloured than before. But the black pro-duced by this ſubſtance ſuggeſts an obvious reaſon for uſing it very ſparingly in thoſe compoſitions of *glaſs*, which are required to be very tranſparent. Nitre or ſalt-petre is alſo uſed with the ſame intention; for by deſtroying, in a certain degree, the phlogiſton, which gives a ſtrong tinge of yellow to *glaſs* prepared with lead as a flux, it ſerves to free it from this coloured tinge; and in ſaline *glaſſes*, nitre is requiſite in a ſmaller proportion to render them ſufficiently tranſparent, as in the caſe of looking-*glaſs*, and other kinds of plates. For an account of Mr. Dollond's excellent contrivance for deſtroying the colours in the object-glaſſes of teleſcopes, &c. ſee ABERRA-TION.

After all, the moſt tranſparent *glaſs* is ſubject to bubbles and veins, the method of preventing which are yet little known; and this is an inconvenience by which Mr. Dol-lond's excellent diſcovery is affected; for the flint *glaſs*, which he uſes, is peculiarly ſubject to ſmall veins, that diſturb the rays in their paſſage, and render the viſion confuſed. This effect is owing to the denſity of theſe veins being greater than that of the reſt of the *glaſs*, as appears from their image received on white paper, when the *glaſs* is held between the paper and a candle, or other luminous object; for this image of a vein, thus receiv-ed, is a line brighter than the reſt of the image of the *glaſs*, and this bright line is defined by a dark edge on each ſide. But the bright line evidently ſhews a conver-gency of rays, which can only be effected by the veins being denſer than the medium in which they are placed. The reaſon why flint *glaſs* is more ſubject to veins than any other *glaſs* is, ſays the tranſlator of Macquer's Che-mical Dictionary, becauſe it is compoſed of materials of more different denſities.

M. Macquer, with a view of improving the manufacture of this *glaſs*, propoſes to facilitate the union of the calx of lead and ſand, of which it is compoſed, by depriving the calx of lead, as much as poſſible, of its phlogiſton, which may be done by combining the vitriolic acid with minium, or red-lead, and expoſing this compoſition to the operation of fire, to diſengage it from the acid, and alſo by giving theſe two ſubſtances the greateſt poſſible degrees of fluidity and mobility, which may be done by mixing with the compoſition of them a conſiderable quantity of ſolvents. Hiſt. Acad. Scienc. for 1773.

As impenetrable as *glaſs* is to the common menſtruums, we find it eaten by the air in length of time, when ex-poſed in old windows; but the effects of its being kept in a ſubterraneous place are much more ſtrange. Borri-chius tells us, that at the time when he was at Rome, there was dug up a whole houſe from under the kitchen garden of a citizen. The houſe had been buried there ten ages, and there were found in it ſeveral glaſs urns, or lacrymatories. The *glaſs* of theſe had no holes made in it, as our old *glaſs* in chamber-windows has, but ſtill retained its ſmooth ſurface and tranſparence; but it was ſplit into a vaſt number of thin lamin, which were as pellucid and fine as Muſcovy glaſs; and in ſome places were tinged with all the beautiful colours that art could have given. We are not acquainted perfectly with the ancient way of working their *glaſs*; but it is not probable there could be any thing particular in the formation of the veſſel, to determine it to ſplit thus into flakes; but that *glaſs* of the ſame kind, in any form, would have done the ſame. Borrich. De Orta Chemiæ.

GLASS, *kinds of*. The manufactured *glaſs* now in uſe may be divided into three general kinds; white tranſparent *glaſs*, coloured *glaſs*, and common green or bottle *glaſs*. Of the firſt kind, there is a great variety; as the flint *glaſs*, as it is called with us, and the German cryſtal *glaſs*, which are applied to the ſame uſes; the *glaſs* for plates for mirrors or looking-*glaſſes*; the *glaſs* for win-dows and other lights; and the *glaſs* for phials and ſmall veſſels. And theſe again differ in the ſubſtances em-ployed as fluxes in forming them, as well as in the coarſe-neſs or fineneſs of ſuch as are uſed for their body. The flint and cryſtal, mirror and beſt window *glaſs*, not only require ſuch purity in the fluxes, as may render it prac-ticable to free the *glaſs* perfectly from all colour; but for the ſame reaſon likewiſe, either the white Lynn ſand, calcined flints, or white pebbles, ſhould be uſed. The others do not demand the ſame nicety in the choice of the materials; though the ſecond kind of window *glaſs*, and the beſt kind of phial, will not be ſo clear as they ought, if either too brown ſand, or impure alkas, be ſuf-fered to enter into their compoſition.

Of coloured *glaſs* there is a great variety of ſorts, dif-fering in their colour, or other properties, according to the occaſions for which they are wanted. The differ-ences in the latter kind depend on the accidental prepa-ration and management of the artiſt by whom they are manufactured. See the ſubſequent articles.

GLASS, *inſtruments for manufacturing*. Theſe are ſubſer-vient to two different purpoſes; viz. the levigation and mixture of the ingredients, and the fuſion or vitrification of them. To the former claſs belong horſe or hand-mills, mortars and peſtles, flat ſtones and mullars, and ſeatces or ſieves. The other ſort of utenſils are furnaces, with the proper iron work, pots for containing the com-poſition when put into the fire, and iron inſtruments for ſhifting the matter out of one into the other, in caſe of accidents; and for taking out ſmall portions, in order to judge of the progreſs of the vitrification, and the quali-ties of the *glaſs*, &c. See the following articles.

GLASS, *method of making white and cryſtal*. There are three ſorts of furnaces uſed in the *glaſs*-works: one to prepare the frit, called the *calcar*; a ſecond, to work the *glaſs*; and a third, called the *lear*, to anneal it. See them all deſcribed under the article FURNACE.

To make cryſtal *glaſs*, take of the whiteſt *tarſo*, pounded ſmall, and ſifted as fine as flour, two hundred pounds; of the ſalt of polverine, a hundred and thirty pounds: mix them together, and put them into the furnace, called the *calcar*, firſt heating it. For an hour keep a moderate fire, and keep ſtirring the materials with a proper rake, that they may incorporate and calcine together; then in-creaſe the fire for five hours; after which take out the matter; which, being now ſufficiently calcined, is called FRIT. From the calcar put the frit in a dry place, and cover it up from the duſt for three or four months.

Now, to make the *glaſs*, or cryſtal: take of this cryſtal frit, called *alio-kalino*; ſet it in pots in the furnace, add-ing to it a due quantity of magneſia, or manganeſe: when the two are fuſed, caſt the fluor into fair water, to clear it of the ſalt, called *ſandiver*; which would other-wiſe make the cryſtal obſcure and cloudy. This lotion muſt be repeated again and again, as often as needful, till the cryſtal be fully purged; or, this ſcum may be taken off by means of proper ladles. Then ſet it to boil four, five, or ſix days; which done, ſee whether it have manganeſe enough; and if it be yet greenith, add more manganeſe, at diſcretion, by little and little at a time, taking care not to overdoſe it, becauſe the manganeſe in-clines it to a blackiſh hue. Then let the metal clarify, till it becomes of a clear and ſhining colour; which done, it is fit to be blown, or formed into veſſels at pleaſure.

GLASS, *flint*, as it is called in our country, is of the ſame general kind with that which in other places is called cryſtal *glaſs*. It has this name from being originally made with calcined flints, before the uſe of the white ſand was underſtood; and retains the name, though no flints are now uſed in the compoſition of it. This flint *glaſs* differs from the other, in having lead for its flux, and white ſand for its body; whereas the fluxes uſed for the cryſtal *glaſs* are alkas or arſenic, and the body conſiſts of calcined flints, or white river pebbles, tarſo, or ſuch ſtones. To the white ſand and lead a proper proportion of nitre is added, to burn away the phlogiſton of the lead, and alſo a ſmall quantity of magneſia; and in ſome works they uſe a proportional quantity of arſenic to aid the fluxing ingredients. The moſt perfect kind of flint *glaſs* may be made by fuſing with a very ſtrong fire a hundred and twenty pounds of the white ſand, fifty pounds of red lead, forty pounds of the beſt pearl-aſhes, twenty pounds of nitre, and five ounces of magneſia. Another compoſition of flint *glaſs*, which is ſaid to come nearer to the kind now made, is the following: a hun-dred and twenty pounds of ſand, fifty four pounds of the beſt pearl-aſhes, thirty-ſix pounds of red-lead, twelve pounds of nitre, and ſix ounces of magneſia. To either of theſe a pound or two of arſenic may be added, to in-creaſe the flux of the compoſition. A cheaper compoſi-tion of flint *glaſs* may be made with a hundred and twenty pounds of white ſand, thirty-five pounds of the beſt pearl-aſhes, forty pounds of red lead, thirteen pounds of nitre, ſix pounds of arſenic, and four ounces of mag-neſia; or, inſtead of the arſenic, may be ſubſtituted fif-teen pounds of common ſalt; but this will be more brittle than the other. The cheapeſt compoſition for the worſt kind of flint *glaſs* conſiſts of a hundred and twenty pounds

pounds of white fand, thirty pounds of red-lead, twenty pounds of the beſt pearl-aſhes, ten pounds of nitre, fifteen pounds of common ſalt, and ſix pounds of arſenic.

The beſt German cryſtal *glaſs* is made of a hundred and twenty pounds of calcined flints, or white ſand, ſeventy pounds of the beſt pearl-aſhes, ten pounds of ſalt-petre, half a pound of arſenic, and five ounces of magneſia.

And a cheaper compoſition is formed of a hundred and twenty pounds of calcined flints or white ſand, forty-ſix pounds of pearl-aſhes, ſeven pounds of nitre, ſix pounds of arſenic, and five ounces of magneſia.

A *glaſs* much harder than any prepared in the common way, may be made by means of borax in the following method: take four ounces of borax, and an ounce of fine ſand; reduce both to a ſubtile powder, and melt them together in a large cloſe crucible ſet in a wind-furnace, keeping up a ſtrong fire for half an hour; then take out the crucible, and when cold break it, and there will be found at the bottom a pure hard *glaſs*, capable of cutting common *glaſs* like a diamond. This experiment, duly varied, may lead to ſeveral uſeful improvements in the art of *glaſs*, enamels, and factitious gems, and ſhews an expeditious method of making *glaſs*, without any fixed alkali, which has been generally thought an eſſential ingredient in *glaſs*, and it is not yet known whether calcined cryſtal, or other ſubſtances, being added to this ſalt inſtead of ſand, it might not make a *glaſs* approaching to the nature of a diamond. Shaw's Lectures, p. 326.

There are three principal kinds of *glaſſes*, diſtinguiſhed by the form or manner of working them; viz. *round glaſs*, as thoſe of our veſſels, phials, drinking-*glaſſes*, &c. *table* or *window-glaſs*, of which there are divers kinds; viz. *crown-glaſs*, *ſaulen-glaſs*, &c. and *plate-glaſs*, or *looking-glaſs*.

GLASS, *working or blowing round*. The working furnace we have obſerved, is round, and has ſix boccas, or apertures: at one of theſe, called the *great bocca*, the furnace is heated, and the pots of frit are at this ſet in the furnace; two other ſmaller holes, called *bocarellas*, ſerve to lade or take out the melted metal, at the end of an iron, to work the *glaſs*. At the other holes they put in pots of fuſible ingredients, to be prepared, and at laſt emptied into the lading pot.

There are ſix pots in each furnace, all made of tobacco-pipe clay, proper to ſuſtain not only the heat of the fire, but alſo the effect of the polverine, which penetrates every thing elſe. There are only two of theſe pots that work: the reſt ſerve to prepare the matter for them. The fire of the furnace is made and kept up with dry hard wood, caſt in, without intermiſſion, at ſix apertures.

When the matter, contained in the two pots, is ſufficiently vitrified, they proceed to blow or faſhion it: the proceſs whereof we ſhall here deliver form Agricola, Dr. Merret, the French Diction. de Commerce, &c.

The operator, or ſervitor (the veſſel being now ſufficiently refined), takes his blowing iron, which is a hollow tube, about two feet and a half long; and dipping it in the melting pot, there turns it about: the metal ſticks to the iron like ſome glutinous, or clammy juice; much like, but more firmly than turpentine, or honey.

For each *glaſs* he dips four times, and at each dip rolls the end of his inſtrument, with the *glaſs* thereon, on a piece of iron, over which is a veſſel of water; the coolneſs whereof helps to conſolidate the *glaſs* more readily, and diſpoſes it the better to bind with the next to be taken out of the pot.

After they have dipt a fourth time, and when there is now matter enough on the inſtrument, the operator begins to blow gently through the iron, by which he raiſes or lengthens it nearly a foot; much as we do by blowing in a bladder, or globe; and to give it a poliſh, he rolls it to and fro on a ſtone, or marble.

This done, he blows a ſecond time, and thus forms the bunch, or belly of the *glaſs*. The matter, by this ſecond blaſt, aſſumes the figure of a gourd, or calebaſs, eighteen or twenty inches in diameter. As often as the operator blows into the iron (which muſt be very often), he removes it haſtily from his mouth to his cheek, leſt he ſhould draw the flame into his mouth, when he re-applies it to the iron.

The operator whirls his iron many times round his head, to lengthen and cool the *glaſs*; ſometimes the *glaſs*, thus blown round, is returned to the fire, where it flattens a little of itſelf: when flatted, it is again taken out, and cooled; and, if needful for the deſign, the workman flats its bottom, by preſſing it on the marble, or moulds it in the ſtamp-irons; and thus delivers it to the maſter-workman, to break off the collet.

The collet, or neck, is the narrow part which cleaves to the iron: to ſet the *glaſs* at liberty, they lay a drop of cold water on the collet; which, by its coldneſs, cuts or cracks about a quarter of an inch: after which, giving it a ſlight blow, the fracture is communicated all around the collet. The waſte piece is thrown by to make green *glaſs*.

This done, they dip an iron rod, or ponteglo, in the melting-pots; and with the matter that ſticks thereto, they apply and faſten it to the bottom of the veſſel oppoſite to the collet. The veſſel, thus ſuſtained by the iron rod, is carried to the great bocca to be heated and ſcaled; and while another perſon takes off the roſe, the former operator reſts, and prepares himſelf for the branching.

To branch, or make the bowl, they thruſt in an inſtrument, called the *paſſage*; and the aperture, opened thereby, they farther augment, and widen with the *procello*: in turning this inſtrument about, to form the bowl, the edge becomes thickened; the *glaſs* being, as it were, doubled in that part; whence the hem obſerved on the circumference of our *glaſſes*. What is ſuperfluous, they cut off with the ſheers.

The veſſel, thus opened, is returned to the great bocca; where being ſufficiently heated a ſecond time, the workman gives the bowl its finiſhing, by turning it about with a circular motion; which it increaſes, in proportion as the bowl opens, and enlarges by means of the heat and agitation.

The *glaſs* thus finiſhed, they carry it from the bocca, ſtill turning it round, to a kind of earthen bench, covered with brands, or coals extinguiſhed: here they let it cool a little, and come to its conſiſtence, having firſt detached it from the iron rod by a ſtroke or two with the hand.

Thus, with blowing, preſſing, ſcalding, amplifying, and cutting, the *glaſs* is framed into the ſhape preconceived in the workman's mind. If need be, he proceeds to put on a foot and handle, or any other decoration.

When the maſter has finiſhed a number of theſe, another ſervitor takes them with an iron fork, and ſpeedily places them in the tower, or leer, to anneal and harden.

What has been here ſaid of white, or cryſtal *glaſs*, holds equally of common, or green *glaſs*, the working being the ſame in all; and the difference only in the ſalt, or polverine, made uſe of.

So many maſters as there are, ſo many pots at the leaſt, and ſo many boccas there muſt be; each man having his proper ſtation: where, ſays Dr. Merret, they receive thoſe ſcorching heats fallying directly into their faces, mouths, and lungs; whence they are forced always to work in their ſhirts, like the Cyclopes, and nudimembra Pyracmones, with a ſtraw broad-brimmed hat on their heads, to defend their eyes from the exceſſive heat and light. They ſit in large, wide, and wooden chairs, with two long elbows, to which their inſtruments are hung. They work ſix hours at a time, meaſured by a ſingle glaſs; after which they are relieved by others, for the like time; ſo that the furnaces are never idle.

Working, or blowing window, or table GLASS. The method of making crown window-*glaſs*, now practiſed in England, is ſaid to have been borrowed from the French. An Engliſh *glaſs* maker went over to work in France, on purpoſe to get into the ſecret; which when he had attained to, he returned, and ſet up a *glaſs-work*, wherein he far outdid the French, his teachers.

This *glaſs* is blown much after the manner of looking-*glaſs*. Some writers, from wrong intelligence, have ſaid that it was run, or caſt in ſand; but the real proceſs is as follows:

The furnace, melting-pots, materials, and fire, are the ſame for window, or *table-glaſs*, as they are for round *glaſs*; and the difference in the operation only commences after the ſervitor has dipped his blowing iron the fourth time in the melted metal.

The *glaſs* then being in this condition, they blow it; but inſtead of rounding, or forming it into a bunch, the particular motion the workman gives it in the directing and managing the wind, and the way of rolling it on the iron, make it extend in length two or three feet, and form a cylinder, which at firſt is but two inches in diameter; but which, by being recommitted to the fire, and blown afreſh when taken out, becomes of the extent required for the table of *glaſs* to be formed; with this circumſtance, however, that the ſide which is faſtened to the iron, goes gradually diminiſhing, and ends in a kind of cone or pyramid.

To render the two ends nearly of the ſame diameter, after adding a little *glaſs* to that oppoſite to the iron, they draw it out with a pair of iron pincers. Then they cut off the ſame end with a little water; and carrying the cylinder back to the bocca, they cut it likewiſe with the ſame in two other places; one place being at the diſtance of eight or ten inches from the iron, and the other throughout the whole length.

The *glass* cylinder, thus abridged of both its extremities, is next heated on a kind of earthen table, somewhat raised in the middle, in order to promote its opening at the place cut longitudinally. The workman here makes use of an iron, wherewith he alternately lowers and raises the two sides, or halves of the cylinder, which now begin to open, and unfold like a sheet of paper, which at length grow perfectly flat. The table of glass is now in its last position, and needs nothing farther but to be heated over again. When taken out, they lay it on a table of copper, whence, after it has cooled, and come to its consistence, they carry it on forks to the tower of the furnace, where they leave it to anneal for twenty-four hours.

The number of tables annealed at a time, which sometimes amount to a hundred, or more, with the perpendicular situation they are set in, occasioned, anciently, that those set in first, sustaining, in some measure, the pressure of the last, were bent, and thus rendered inconvenient for use; but this inconvenience is now remedied, by separating them into tens, with an iron sliver; which, diminishing the weight, by dividing it, keeps the tables as flat and even as they were put in.

GLASS, *kinds of table or window*. There are divers sorts of this *glass* made in divers places, for the use of building, those most known among us, are given us by the author of the Builder's Dictionary, as follows.

GLASS, *crown*, of which, says Neve, there are two kinds, distinguished by the places where they are wrought; viz.

1. *Ratcliff crown glass*, which is the best and clearest, and was first made at the Bear-garden, on the Bank-side, Southwark, but since at Ratcliff: of this there are twenty-four TABLES to the CASE, the tables being of a circular form, about three feet six inches in diameter.

2. *Lambeth crown glass*, which is of a darker colour than the former, and more inclining to green.

The best window, or crown *glass*, is made of white sand, sixty pounds; of purified pearl-ashes, thirty pounds; of salt-petre, fifteen pounds; of borax one pound; and of arsenic, half a pound. If the *glass* should prove yellow, magnesia must be added. A cheaper composition for window *glass* consists of sixty pounds of white sand, twenty-five pounds of unpurified pearl-ashes, ten pounds of common salt, five pounds of nitre, two pounds of arsenic, and one ounce and a half of magnesia. The common or green window *glass*, is composed of sixty pounds of white sand, thirty pounds of unpurified pearl-ashes, ten pounds of common salt, two pounds of arsenic, and two ounces of magnesia. But a cheaper composition for this purpose, consists of a hundred and twenty pounds of the cheapest white sand, thirty pounds of unpurified pearl-ashes, sixty pounds of wood ashes, well burnt and sifted, twenty pounds of common salt, and five pounds of arsenic.

GLASS, *French*, as also called *Normandy glass*, and formerly *Lorraine glass*, because made in those provinces: at present it is made wholly in the nine *glass* works; five whereof are in the forest of Lyons, four in the county of Eu; the last at Beaumont, near Rouen. It is of a thinner kind than our crown *glass*; and when laid on a piece of white paper, appears of a dirtyish green colour. There are but twenty-five TABLES of this to the CASE.

GLASS, *German*, is of two kinds, the *white* and the *green*: the first is of a whitish colour, but is subject to those small curved streaks, observed in our Newcastle *glass*, though free from the spots and blemishes thereof. The *green*, besides its colour, is liable to the same streaks as the white; but both of them are thinner, and less warped, than our Newcastle *glass*.

GLASS, *Dutch*, is not much unlike our Newcastle *glass*, either in colour or price. It is frequently much warped, like that; and the tables are but small.

GLASS, *Newcastle*, is that most used in England. It is of an ash colour, and much subject to specks, streaks and other blemishes; and, besides, is frequently warped. Leybourn says, there are forty-five tables to the case, each containing five superficial feet: some say there are but thirty-five tables, and six feet in each table.

GLASS, *phial*, is a kind of *glass* betwixt the flint *glass* and the common bottle, or green *glass*. The best kind may be prepared with a hundred and twenty pounds of white sand, fifty pounds of unpurified pearl-ashes, ten pounds of common salt, five pounds of arsenic, and five ounces of magnesia. The composition for green or common phial *glass*, consists of a hundred and twenty pounds of the cheapest white sand, eighty pounds of wood-ashes, well burnt and sifted, twenty pounds of pearl-ashes, fifteen pounds of common salt, and one pound of arsenic.

GLASS, *common bottle*, or *green*, is formed of sand of any kind, fluxed by the ashes of burnt wood, or of any parts of vegetables; to which may be added the *scoriæ* or clinkers of forges. When the softest sand is used, two hundred pounds of wood ashes will suffice for a hundred pounds of sand, which are to be ground and mixed together. The composition with the clinkers consists of a hundred and seventy pounds of wood ashes, a hundred pounds of sand, and fifty pounds of clinkers, or *scoriæ*, which are to be ground and mixed together. If the clinkers cannot be ground, they must be broke into small pieces, and mixed with the other matter without any grinding.

Working of PLATE, or LOOKING-GLASS. The materials whereof *looking-glass* is made, are much the same as those of other works of *glass*, viz. an alkali salt, and sand.

The salt, however, it is to be observed, should not be that extracted from polverine, or the ashes of the Syrian kali; but that from barilla, or the ashes of a plant of that name of the genus of kalis, but growing about Alicant in Spain. It is very rare that we can have the barilla pure; the Spaniards, in burning the herb, make a practice of mixing another herb along with it, which alters its quality; or of adding sand to it, to increase the weight, which is easily discovered, if the addition be only made after the boiling of the ashes, but next to impossible if made in the boiling. It is from this adulteration that those threads and other defects in *plate-glass* arise. To prepare the salt, they clean it well of all foreign matters; pound or grind it with a kind of mill, and finally sift it pretty fine.

Pearl-ashes, properly purified, will furnish the alkali salt requisite for this purpose; but it will be necessary to add borax, or common salt, in order to facilitate the fusion, and prevent the *glass* from stiffening in that degree of heat, in which it is to be wrought into plates. For purifying the pearl-ashes, dissolve them in four times their weight of boiling water, in a pot of cast iron, always kept clean from rust. Let the solution be removed into a clean tub, and remain there twenty-four hours, or longer. Having decanted the clear part of the fluid from the dregs or sediment, put it again in the iron pot, and evaporate the water till the salts are left perfectly dry. Preserve them in stone jars, well secured from air and moisture.

Pearl-ashes may also be purified in the highest degree, so as to be proper for the manufacture of the most transparent *glass*, by pulverizing three pounds of the best pearl-ashes, with six ounces of salt petre, in a *glass* or marble mortar, till they are well mixed; and then putting part of the mixture into a large crucible, and exposing it in a furnace to a strong heat. When this is red-hot, throw in the rest gradually; and when the whole is red-hot, pour it out on a moistened stone or marble, and put it into an earthen or clean iron pot, with ten pints of water; heat it over the fire, till the salts be entirely melted; let it then stand to cool, and filter it through paper in a pewter cullender. When it is filtered, put the fluid again into the pot, and evaporate the salt to dryness, which will then be as white as snow; the nitre having burnt all the phlogistic matter that remained in the pearl-ashes, after their former calcination.

As to the sand, it is to be sifted and washed, till such time as the water come off very clear; and when it is well dried again, they mix it with the salt, passing the mixture through another sieve. This done, they lay them in the annealing furnace for about two hours; in which time the matter becomes very light and white: in this state they are called *frit*, or *fritta*; and are to be laid up in a dry clean place, to give them time to incorporate: they lie here for at least a year.

When they would employ this frit, they lay it for some hours in the furnace, adding to some the fragments or shards of old and ill made *glasses*; taking care first to calcine the shards by heating them red hot in the furnace, and thus casting them into cold water. To the mixture must likewise be added manganese, to promote the fusion and purification.

The best composition for *looking-glass* plates consists of sixty pounds of white sand cleansed, twenty-five pounds of purified pearl-ashes, fifteen pounds of salt-petre, and seven pounds of borax. If a yellow tinge should affect the *glass*, a small proportion of magnesia, mixed with an equal quantity of arsenic, should be added. An ounce of the magnesia may be first tried; and if this proves insufficient, the quantity should be increased.

A cheaper composition for *looking-glass* plate consists of sixty pounds of the white sand, twenty pounds of pearl ashes, ten pounds of common salt, seven pounds of nitre, two pounds of arsenic, and one pound of borax. The matter of which the *glasses* are made at the famous manufacture of St. Gobin, in France, is a composition of solder, and of a very white sand, which are carefully cleaned of all heterogeneous bodies; afterwards washed for several times, and dried so as to be pulverized in

mill, conſiſting of many peſtles, which are moved by horſes. When this is done, the ſand is ſifted through ſilk ſieves, and dried.

The matter, thus far prepared, is equally fit for *plate-glaſs*, to be formed either for blowing or by caſting.

The largeſt *glaſſes* at St. Gobin are run; the middle-ſized and ſmall ones are blown.

*Blowing looking-*GLASS *plates.* The workhouſes, furnaces, &c. uſed in the making of this kind of *plate-glaſs*, are the ſame, except that they are ſmaller, and that the carquaiſſes, are diſpoſed in a large covered gallery, over againſt the furnace, as thoſe in the following article, to which the reader is referred.

After the materials are vitrified by the heat of the fire, and the *glaſs* is ſufficiently refined, the workman dips in his blowing iron, ſix feet long, and two inches in diameter, ſharpened at the end, which is put in the mouth, and widened at the other, that the matter may adhere to it. By this means he takes up a ſmall ball of matter, which ſticks to the end of the tube by conſtantly turning it. He then blows into the tube, that the air may ſwell the annexed ball; and carrying it over a bucket of water, which is placed on a ſupport at the height of about four feet, he ſprinkles the end of the tube to which the matter adheres, with water, ſtill turning it, that, by this cooling, the matter may coaleſce with the tube, and be fit for ſuſtaining a greater weight. He dips the tube again into the ſame pot, and proceeds as before; and, dipping it in the pot a third time, he takes it out, loaded with matter, in the ſhape of a pear, about ten inches in diameter, and a foot long, and cools it at the bucket; at the ſame time blowing into the tube, and, with the aſſiſtance of a labourer, giving it a balancing motion, he cauſes the matter to lengthen; which, by repeating this operation ſeveral times, aſſumes the form of a cylinder, terminating like a ball at the bottom, and in a point at the top. The aſſiſtant is then placed on a ſtool three feet and a half high; and on this ſtool there are two upright pieces of timber, with a croſs beam of the ſame, for ſupporting the glaſs and tube, which are kept in an oblique poſition by the aſſiſtant, that the maſter workman may with a punchion ſet in a wooden handle, and with a mallet, make a hole in the maſs: this hole is drilled at the centre of the ball that terminates the cylinder, and is about an inch in diameter. When the *glaſs* is pierced, the defects of it are perceived; if it is tolerably perfect, the workman lays the tube horizontally on a little iron treſſel, placed on the ſupport of the aperture of the furnace. Having expoſed it to the heat for about half a quarter of an hour, he takes it away, and with a pair of long and broad ſhears, extremely ſharp at the end, widens the *glaſs*, by inſinuating the ſhears into the hole made with the punchion, whilſt the aſſiſtant, mounted on the ſtool, turns it round, till, at laſt, the opening is ſo large as to make a perfect cylinder at bottom. When this is done, the workman lays his *glaſs* upon the treſſel, at the mouth of the furnace, to heat it; he then gives it to his aſſiſtant on the ſtool, and with large ſhears cuts the maſs of matter up to half its height. There is at the mouth of the furnace an iron tool, called *pontil*, which is now heating, that it may unite and coaleſce with the *glaſs* juſt cut, and perform the office which the tube did before it was ſeparated from the *glaſs*. This pontil is a piece of iron, ſix feet long, and in the form of a cane or tube, having at the end of it a ſmall iron bar, a foot long, laid equally upon the long one, and making with it a T. This little bar is full of the matter of the *glaſs*, about four inches thick. This red-hot pontil is preſented to the diameter of the *glaſs*, which coaleſces immediately with the matter round the pontil, ſo as to ſupport the *glaſs* for the following operation. When this is done, they ſeparate the tube from the *glaſs*, by ſtriking a few blows with a chiſſel upon the end of the tube, which has been cooled; ſo that the *glaſs* breaks directly, and makes this ſeparation, the tube being diſcharged of the *glaſs* now adhering to the pontil. They next preſent to the furnace the pontil of the *glaſs*, laying it on the treſſel to heat, and holden the end of that *glaſs*, that the workman may open it with his ſhears, as he has already opened one end of it, to complete the cylinder; the aſſiſtant holding it on his ſtool as before. For the laſt time, they put the pontil on the treſſel, that the *glaſs* may become red-hot, and the workman cuts it quite open with his ſhears, right over-againſt the forementioned cut; this he does as before, taking care that both cuts are in the ſame line. In the mean time, the man who looks after the carquaiſſes, comes to receive the *glaſs* upon an iron ſhovel, two feet and a half long without the handle, and two feet wide, with a ſmall border of an inch and a half to the right and left, and towards the handle of the ſhovel. Upon this the *glaſs* is laid, flattening it a little with a ſmall ſtick a foot and a half long, ſo that the cut of the *glaſs* is turned upwards. They ſeparate the *glaſs* from the pontil, by ſtriking a few gentle blows between the two with a chiſſel. The *glaſs* is then removed to the mouth of the hot carquaiſſe, where it becomes red-hot gradually: the workman, with an iron tool, ſix feet long, and widened at the end in form of a club at cards, four inches long, and two inches wide on each ſide, very flat, and not half an inch thick, gradually lifts up the cut part of the *glaſs*, to unfold it out of its form of a flattened cylinder, and render it ſmooth, by turning it down upon the beauft of the carquaiſſe. The tool, already deſcribed, being inſinuated within the cylinder, performs this operation, by being puſhed hard againſt all the parts of the *glaſs*. When the *glaſs* is thus made quite ſmooth, it is puſhed to the bottom of the carquaiſſe, or annealing furnace, with a ſmall iron raker, and ranged there with a little iron hook. When the carquaiſſe is full, it is ſtopped and cemented as in the caſe of run *glaſſes*, and the *glaſs* remains there for a fortnight to be annealed; after which time, they are taken out to be poliſhed. A workman can make but one *glaſs* in an hour, and he works and reſts for ſix hours alternately.

It may be obſerved, that *looking-glaſſes*, thus blown, ſhould never be above forty-five, or at moſt fifty inches long, and of a breadth proportionable. Thoſe exceeding theſe dimenſions, as we frequently find among the Venice *glaſſes*, cannot have the thickneſs ſufficient to bear the grinding; and beſides are ſubject to warp, which prevents them from regularly reflecting objects.

*Caſting or running large Looking-*GLASS *plates.* This art is of French invention, and not quite one hundred years old. It is owing to the Sieur Abraham Thevart, who firſt propoſed it to the court of France, in 1688.

It is performed much like the caſting of ſheet lead among the plumbers; and by means hereof we are not only enabled to make *glaſſes* of more than double the dimenſions of any made by the Venetian way of blowing; but alſo to caſt all kinds of borders, mouldings, &c.

The furnaces for melting the materials of this manufacture are of enormous ſize; and thoſe for annealing the *glaſſes*, when formed, are much more ſo. Round a melting-furnace, there are at leaſt twenty-four annealing furnaces or ovens; each from twenty to twenty-five feet long; they are called carquaiſſes: each carquaiſſe has two tiſſarts, or apertures, to put in wood, and two chimneys. Add, that beſide the annealing furnaces, &c. there are others for making of frit, and calcining old pieces of *glaſs*.

All theſe furnaces are covered over with a large ſhed; under which are likewiſe forges, and workhouſes for ſmiths, carpenters, &c. continually employed in repairing and keeping up the machines, furnaces, &c. as alſo lodges, and apartments for thoſe, and the other workmen, employed about the *glaſs*, and keeping up a perpetual fire in the great furnace; ſo that the *glaſs-houſe*, as that in the caſtle of St. Gobin, in the foreſt of Fere, in the Soiſſonois, appears more like a little city, than a manufactory.

The inſide of furnaces is formed of a ſort of baked earth proper to ſuſtain the action of fire; and the ſame earth ſerves alſo for melting-pots, ciſterns, &c. The furnaces ſeldom laſt above three years; after which they are to be rebuilt, from bottom to top; and to keep them good, even for that time, the inſide muſt be refitted every ſix months, at which time the fire is extinguiſhed. The ſmelting-pots are as big as wine hogſheads, about three feet in height, and in diameter; and contain above two thouſand weight of metal. The ciſterns, or pans, are much ſmaller, being about thirty-ſix inches long, eighteen inches wide, and as many deep: and ſerve for the conveyance of liquid *glaſs*, which is drawn out of the pots, to the caſting tables.

When the furnace is in condition to receive the pots and ciſterns, they heat it red-hot, which requires fifty cords, or a hundred cart-loads of wood: this done, they fill the pots with the materials, or ſolder and ſand, which is done at ſeveral times, to facilitate the fuſion. When the matter is ſufficiently vitrified, refined, and ſettled, which uſually happens in thirty-ſix hours, they fill the ciſterns, which are in the ſame furnace, and which are left there about ſix hours longer, till ſuch time as they appear all white, through the exceſſive heat.

To get the ciſterns with the metal out of the furnace, they make uſe of a large iron chain, which opens and ſhuts with hooks and eyes. From the middle hereof, on each ſide, ariſe two maſſive iron pins, whereby, with the aſſiſtance of pullies, the ciſterns are raiſed upon a kind of carriage of a proper height; and thus conducted to the table where the *glaſs* is to be run. The ciſterns, then raiſed above the tables with an engine, in form of a crane, by means of two iron bars, ſo contrived as to throw the ciſtern into an inclined poſition, which diſ-

charges

charges a torrent of matter, all on fire, wherewith the table, prepared for that purpose, is presently covered.

The table, whereon the *glass* is to be run, is of cast iron, about ten feet long, and five feet broad. It is supported on a wooden frame, with truckles, for the convenience of removing from one carquaisse, or annealing furnace, to another, in proportion as they are filled.

To form the thickness of a *glass*, there are two iron rulers or rims, placed round the edge of the table; and on these rest the two extremes of a kind of roller, of cast iron, which serves to drive the liquid matter before it to the end of the table, or mould. The iron rulers, being moveable, and capable of being set closer, or farther apart, at pleasure, determine the width of the *glasses*, and retain the matter, that it does not run off at the edges.

At soon as the matter is arrived at the end of the table, and the *glass* is come to a consistence, examined by the directors of the manufacture, and approved, they shove it off into the annealing furnace, with an iron raker, as wide as the table, that has a handle two fathoms long; being assisted by workmen on the other side of the carquaisse, who, with iron hooks, pull the *glass* to them, and range it in the carquaisse, which holds six large *glasses*.

What is most surprising throughout the whole of this operation, is, the quickness and address, wherewith such massy cisterns, filled with a flaming matter, are taken out of the furnace, conveyed to the table, and poured therein, the *glass* spread, &c. The whole is inconceivable to such as have not been eye-witnesses of that surprising manufacture.

As fast as the cisterns are emptied, they carry them back to the furnace and take fresh ones, which they empty as before. This they continue to do, so long as there are any full cisterns; laying as many plates in each carquaisse as it will hold, and stopping them up with doors of baked earth, and every chink with cement, as soon as they are full, to let them anneal, and cool again, which requires about fourteen days.

The first running being dispatched, they prepare another, by filling the cisterns anew, from the matter in the pots; and after the second, a third; and even a fourth time, till the melting-pots are quite empty.

The cisterns at each running should remain at least six hours in the furnace to whiten; and when the first annealing furnace is full, the casting-table is to be carried to another. It need not here be observed, that the carquaisses, or annealing furnaces, must first have been heated to the degree proper for them. It may be observed, that the oven-full, or the quantity of matter commonly prepared, supplies the running of eighteen *glasses*, which is performed in eighteen hours, being an hour for each *glass*. The workmen work six hours, and are then relieved by others.

When the pots are emptied, they take them out, as well as the cisterns, to scrape off what *glass* remains, which otherwise would grow green by continuance of fire, and spoil the *glasses*. They are not filled again in less than thirty-six hours, so that they put the matter into the furnace, and begin to run it every fifty-four hours.

The manner of heating the large furnaces is singular enough: the two stors, or persons employed for that purpose, in their shirts, run round the furnace without making the least stop, with a speed scarce inferior to that of the lightest courier: as they go along, they take two billets, or pieces of wood, which are cut for the purpose; these they throw into the first stfart; and continuing their course, do the same for the second. This they hold without interruption for six hours successively; after which they are relieved by others, &c. It is surprising that two such small pieces of wood, and which are consumed in an instant, should keep the furnace to the proper degree of heat; which is such, that a large bar of iron, laid at one of the mouths of the furnace, becomes red-hot in less than half a minute.

It is computed, that a furnace, before it be fit to run *glass*, costs above three thousand five hundred pounds; that at least six months are required for the building it anew, and three months for the refitting it; and that when a pot of matter bursts in the furnace, the loss of matter and time amounts to above two hundred and fifty pounds.

The *glass*, when taken out of the melting-furnace, needs nothing farther but to be ground, polished, and foliated. There is an inland duty of 9*s.* 4*d.* a hundred weight on all materials, &c. for making of crown, plate, and flint *glass*, and all white *glass*; and of 2*l.* 4*d.* a hundred weight on all materials for making common bottles, and other green *glass*. Upon all crown, plate, and flint *glass* imported, there is a duty of 3*d.* per pound weight; and on all green, or other *glass* imported, 2*d.* per pound weight; and on all quart bottles and flasks imported, 2*l.* per dozen; and on all bottles and flasks imported, containing more or less than a quart, 2*s.* per dozen quarts. And if any of the above be landed before entry and payment of duties, they shall be forfeited; and no person is allowed to import into Ireland any of these, that are not of the manufacture of Great Britain, under the penalty of forfeiting the same and ship, and 10*l.* a pound. *Glass* exported is entitled to a drawback of the duty. 19 Geo. II. cap. 12.

GLASS, *annealing of*. The operation of annealing of *glass* is performed in a peculiar furnace called the *leer*, which consists of two parts, the *tower* and the *leer*. The vessels as soon as made are placed by the servitors on the floor of the former, to anneal: which done, they are drawn slowly in a sort of pan, called *frasches*, by an operator called the *sarlo-man*, all along the *leer*, the space of five or six yards, to give them time to cool gradually; so that when they reach the mouth of the *leer*, they are found quite cold. Mertet, Not. to Neri, p. 243, seq.

The particles of *glass* by annealing are supposed to lose part of their springiness, and their brittleness at the same time. A gradual heating or cooling of *glass*, according to Dr. Hook, *anneals* or reduces its parts to a texture more loose, and easy to be broke; but withal more flexible than before. And hence in some measure the phenomena of *glass-drops*.

Borrichius, in his Chemistry, seems to think that the rendering *glass* ductile or malleable, is not so impracticable as it is usually thought: in support of this, he alleges the instance of the *luna cornea*, which is a sort of salt made of silver dissolved in an acid, and which is in some degree ductile, and so far altered from the nature of silver, that it may be melted at a candle, and reduced into small transparent leaves; and adding to this the process for making a ductile salt out of common sal ammoniac, dissolved in a large *glass*, and crystallized a vast many times, the crystals of this salt, he says, at last became half a foot long, and were flexible and elastic, and in some degree ductile under a hammer. From these changes in bodies naturally brittle as salts are, he judges that the same changes may be made in *glass*. Phil. Trans. N° 39.

Glasses unannealed are so excessively brittle, as to fly and break of themselves, even frequently before they are well cold. Hence the practice of nealing or annealing was devised.

Some of the phenomena depending on the fragility of unannealed *glass* deserve the attention of the curious. Those of the lacrymæ, or *glass-drops*, were among the first taken notice of; and it has also been observed, that hollow bells made of unannealed *glass*, with a small hole in them, will fly to pieces, by the heat of the hand only, if the hole by which the internal and external air communicate, be stopped with a finger. Phil. Trans. N° 477. § 3. See RUPERT's *Drops*.

But lately some vessels made of such unannealed *glass* have been discovered, which have the remarkable property of resisting very hard strokes given from without, though they shiver to pieces by the shocks received from the fall of very light and minute bodies dropped into their cavities. These *glasses* may be made of any shape; all that needs be observed in making them, is to take care that their bottoms may be thicker than their sides. The thicker the bottom is, the easier do the *glasses* break. One whose bottom is three fingers breadth in thickness, flies with as much ease at least as the thinest *glass*. Some of these vessels have been tried with strokes of a mallet, sufficient to drive a nail into wood tolerably hard, and have held good without breaking. They also resist the shock of several heavy bodies let fall into their cavities, from the height of two or three feet. For instance, musket-balls, pieces of iron, or other metal; pyrites, jasper, wood, bone, &c. but this is not surprising, as other *glasses* of the same size do the same. But the wonder is, that taking a shiver of flint of the size of a small pea, and letting it fall into the *glass* only from the height of three inches, in about two seconds the *glass* flies, and sometimes in the very moment of the shock: nay, a bit of flint no larger than a grain, drop into several *glasses* successively; though it did not immediately break them, yet they all flew, being set by, in less than three quarters of an hour. Phil. Trans. ibid. p. 509.

Some other bodies produce a like effect with flint: for instance, sapphire, porcelain, diamonds, hard tempered steel, as also marbles, such as boys play with; to which add pearls from the animal kingdom.

The experiments succeeded also when the *glasses* were held in the hand, rested on a pillow, put in water, or filled with water. It is also remarkable, that the *glass* broke, upon their bottoms being slightly rubbed with the finger, though some of them did not fly till half an hour after the rubbing.

If the *glasses* be every where extremely thin, they do not break in theſe circumſtances.

Some have pretended to account for theſe phenomena, by ſaying, that the bodies dropped into theſe veſſels cauſe a concuſſion, that is ſtronger than the cohesion of the parts of the *gliſs*, and that conſequently a rupture of the ſame muſt enſue. But why does not a ball of gold, ſilver, iron, copper, or ſeveral other bodies, even a thouſand times heavier than a ſhiver of flint, equally cauſe this concuſſion, and break the *glaſſes*?

Mr. Euler has endeavoured to account for theſe appearances from his principles of percuſſion. He thinks this experiment entirely overthrows the opinion of thoſe who meaſure the FORCE of perenſſion by the *vis viva*; and he thinks the principles he has eſtabliſhed give a clear ſolution of this phenomenon. According to theſe principles, the extreme hardneſs of the flint, and alſo its angular figure, which makes the ſpace of contact with the *glaſs-veſſel* extremely ſmall, ought to cauſe an impreſſion on the *glaſs* vaſtly greater than lead or any other metal; and this may account for the flint's breaking the veſſel, though the bullet, even falling from a conſiderable height, does no damage. Mem. Acad. Berlin. 1745. p. 47.

Hollow cups made of the green *bottle-glaſs*, ſome of them three inches thick at bottom, were inſtantly broken, by a ſhiver of flint weighing about two grains, though they had reſiſted the ſhock of a muſket ball from the height of three feet. Phil. Tranſ. ibid. p. 515.

GLASS *of Antimony*, in *Chemiſtry*. See *Glaſs of* ANTIMONY, and VITRUM *antimonii ceratum*.

GLASS, *axungia of*. See AXUNGIA and SANDIVER.

GLASS *of borax*. See BORAX.

GLASS, *coloring of*. That the colours given to *glaſs* may have their full beauty, it muſt be obſerved, that every pot when new, and firſt uſed, leaves a foulneſs in the *glaſs* from its own earthy parts; ſo that a coloured *glaſs* made in a new pot can never be bright, or perfectly fine. For this reaſon, the larger of theſe, when new, may be glazed with white *glaſs*; but the ſecond time of uſing, the pots loſe this foulneſs.

The glazing may be done by reducing the *glaſs* to powder, and moiſtening the inſide of the pot with water; while it is yet moiſt, put in ſome of the powdered *glaſs*, and ſhake it about, till the whole inner ſurface of the pot be covered by as much as will adhere to it, in conſequence of the moiſture. Throw out the redundant part of the powdered *glaſs*; and the pot being dry, ſet it in a furnace ſufficiently hot to vitrify the *glaſs* adhering to it, and let it continue there ſome time; after which, care muſt be taken to let it cool gradually.

Theſe pots which have ſerved for one colour muſt not be uſed for another; for the remainder of the old matter will ſpoil the colour of the new. The colours muſt be very carefully calcined to a proper degree; for if they are calcined either too much or too little, they never do well; the proper proportion, as to quantity, muſt alſo carefully be regarded, and the furnaces muſt be fed with dry, hard wood. And all the proceſſes ſucceed much the better if the colour be uſed divided; that is, a part of it in the frit, and the reſt in the melted metal.

A hard *glaſs*, proper for receiving colours, may be prepared by pulverizing twelve pounds of the beſt ſand, cleanſed by waſhing in a *glaſs* or flint mortar, and mixing ſeven pounds of pearl aſhes, or any fixed alkaline ſalt, purified with nitre (ſee *Plate* or *Larking*-GLASS, above), one pound of ſalt-petre, and half a pound of borax, and pounding them together. A *glaſs* leſs hard may be prepared of twelve pounds of white ſand cleanſed, ſeven pounds of pearl-aſhes, purified with ſalt-petre, one pound of nitre, half a pound of borax, and four ounces of arſenic, prepared as before.

GLASS, *amethyſt coloured*. See *Purple* GLASS, and AMETHYST.

GLASS, *bolus-coloured*, is made thus: put into a pot cryſtal frit, three waſhed in water; tinge this with manganeſe, prepared into a clear purple; to this add *alumen catinum*, fixed fine, in ſmall quantities, and at ſeveral times; this will make the *glaſs* grow yellowiſh, and a little reddiſh, but not blackiſh, and always diſſipates the manganeſe. The laſt time you add manganeſe give no more of the *alumen catinum*, unleſs the colour be too full. Thus will the *glaſs* be exactly of the colour of the *bolus-ruby*. See *Ruby* GLASS.

GLASS, *to give the common black colour to*, the *glaſs-makers* uſe the following method: they take old broken *glaſs* of different colours, grind it to powder, and add to it, by different parcels, a ſufficient quantity of a mixture of two parts zaffer, and one part manganeſe: when well purified, they work it into veſſels, &c.

Glaſs BEADS are coloured with manganeſe only. See *Black* ENAMEL.

To give GLASS *the colour of black velvet*. The manner of giving this deep and fine colour to *glaſs*, is this: take of cryſtalline and pulverine frit, of each twenty pounds; of calx of lead and tin four pounds; ſet all together in a pot in the furnace, well heated; when the glaſs is melted and pure, take ſteel well calcined and powdered, half of iron that fly off from the ſmith's anvil, of each equal quantity; powder and mix them well; then put ſix ounces of this powder to the above melted metal, while in fuſion; mix the whole thoroughly together, and let all boil ſtrongly together; then let it ſtand in fuſion twelve hours to purify, and after this work it. It will be a moſt excellent *velvet* black.

There is another way of doing this, which alſo produces a very fair black. It is this: take a hundred pounds of rochetta frit, add to this two pounds of tartar, and ſix pounds of manganeſe, both in fine powder; mix them well, and put them to the metal while in fuſion, at different times, in ſeveral parcels; let it ſtand in fuſion after this for four days, and then work it. Neri.

A *glaſs* perfectly black may alſo be formed of ten pounds of either of the compoſitions for hard *glaſs*, above deſcribed, one ounce of zaffer, ſix drams of manganeſe, and an equal quantity of iron ſtrongly calcined.

GLASS, *blue, of a ſky colour*, may be made by adding ſix drams of zaffer, and two drams of manganeſe, to ten pounds of either of the compoſitions for hard *glaſs*, deſcribed above under *Colouring of* GLASS. For a very cool or pure blue *glaſs*, half an ounce of calcined copper may be uſed inſtead of the manganeſe, and the proportion of zaffer diminiſhed by one half. *Glaſs* reſembling SAPPHIRE may be made with ten pounds of either of the compoſitions for hard *glaſs*, three drams, and one ſcruple of zaffer, and one dram of the *calx auſta*, or precipitation of gold by tin; or inſtead of this latter ingredient, two drams and two ſcruples of manganeſe. Or, a ſapphire-coloured *glaſs* may be made by mixing with any quantity of the hard *glaſs* one eighth of its weight of ſmalt.

GLASS, *brown Venetian, with gold ſpangles*, commonly called the *philoſopher's ſtone*, may be prepared in the following manner: take of the ſecond compoſition for hard *glaſs* above deſcribed, and of the compoſition for EASTS, of each five pounds, and of highly calcined iron an ounce; mix them well, and fuſe them till the iron be perfectly vitrified, and has tinged the *glaſs* of a deep tranſparent, yellow brown colour. Powder this *glaſs*, and add to it two pounds of powdered *glaſs* of antimony; grind them together, and thus mix them well. Take part of this mixture, and rub into it fourſcore or one hundred leaves of the counterfeit leaf gold, called Dutch gold; and, when the parts of the gold ſeem ſufficiently divided, mix the powder containing it with the other part of the *glaſs*. Fuſe the whole with a moderate heat, till the powder run into a viſcous maſs, fit to be wrought into any of the figures or veſſels into which it is uſually formed; but avoid a perfect liquefaction; becauſe that, in a ſhort time, deſtroys the equal diffuſion of the ſpangles, and vitrifies, at leaſt in part, the matter of which they are compoſed; converting the whole into a kind of tranſparent, olive-coloured *glaſs*. This kind of *glaſs* is uſed for a great variety of toys and ornaments with us, who, at preſent, procure it from the Venetians. Handmaid to the Arts, vol. ii. p. 317. See *Gold-coloured* GLASS.

GLASS-*chalcedony*. A mixture of ſeveral ingredients, with the common matter of *glaſs*, will make it reſemble the ſemi-opake gems, the jaſpers, agates, chalcedonies, &c. The way of making theſe ſeems to be the ſame thing with the method of making marbled paper, by ſeveral colours diſſolved in ſeveral liquors, which are ſuch as will not readily mix with one another when put into water, before they are caſt upon the paper which is to be coloured. There are ſeveral ways of making theſe variouſly coloured *glaſſes*, but the beſt is this: diſſolve four ounces of fine leaf ſilver in a *glaſs* veſſel in ſtrong aqua fortis; ſtop up the veſſel, and let it aſide.

In another veſſel, diſſolve five ounces of quickſilver in a pound of aqua fortis, and ſet this aſide.

In another *glaſs* veſſel, diſſolve two pound of aqua fortis three ounces of fine ſilver, firſt calcined in this manner: amalgamate the ſilver with mercury, mix the amalgama with twice its weight of common ſalt well purified, put the mixture in an open fire in a crucible, that the mercury may fly off, and the ſilver be left in form of powder. Mix this powder with an equal quantity of common ſalt well purified, and calcine this for ſix hours in a ſtrong fire; when cold, waſh off the ſalt by repeated boilings in common water, and then put the ſilver into the aqua fortis. Set this ſolution alſo aſide.

In another veſſel, diſſolve in a pound of aqua fortis three ounces of ſal ammoniac; pour off the ſolution, and diſſolve in it a quarter of an ounce of gold. Set this alſo aſide.

In another veſſel, diſſolve three ounces of ſal ammoniac in a pound of aqua fortis; then put into the ſolution cinnabar, crocus martis, ultramarine, and ferretto of Spain, of each half an ounce. Set this alſo aſide.

In another veſſel, diſſolve in a pound of aqua fortis three ounces of ſal ammoniac; then put into it crocus martis, made with vinegar, calcined tin, caſſer, and cinnabar, of each half an ounce; let each of theſe be powdered very fine, and put gently into the aqua fortis. Set this alſo aſide.

In another veſſel, diſſolve three ounces of ſal ammoniac in a pound of aqua fortis, and add to it braſs calcined with brimſtone, braſs thrice calcined, manganeſe, and ſcales of iron which fall from the ſmith's anvil, of each half an ounce; let each be well powdered, and put gently into the veſſel. Then ſet this alſo aſide.

In another veſſel, diſſolve two ounces of ſal ammoniac in a pound of aqua fortis, and put to it vetrifiable ſalt ounce, red lead, crude antimony, and the caput mortuum of vitriol, of each half an ounce: put theſe well powdered leiſurely into the veſſel, and ſet this alſo aſide.

In another veſſel, diſſolve two ounces of ſal ammoniac in a pound of aqua fortis, and add orpiment, white arſenic, painters lake, of each half an ounce: keep theſe nine veſſels in a moderate heat for fifteen days, ſhaking them well at times. After this pour all the matters from theſe veſſels into one large veſſel, well luted at its bottom; let this ſtand ſix days, ſhaking it at times, and then ſet it in a very gentle heat, and evaporate all the liquor, and there will remain a powder of a purpliſh green.

When this is to be wrought, put into a pot very clear metal, made of broken cryſtalline and white *glaſs*, that has been uſed; for with the virgin-frit, or ſuch as has never been wrought, the chalcedony can never be made, as the colours do not ſtick to it, but are conſumed by the frit. To every pot of twenty pounds of this metal put two or three ounces of this powder at three ſeveral times; incorporate the powder well with the *glaſs*, and let it remain an hour between each time of putting in the powders. After all are in, let it ſtand twenty-four hours; then let the *glaſs* be well mixed, and take an aſſay of it, which will be found of a yellowiſh blue; return this many times into the furnace; when it begins to grow cold, it will ſhew many waves of different colours very beautifully. Then take tartar eight ounces, ſoot of the chimney two ounces, crocus martis made with brimſtone, half an ounce; let theſe be well powdered and mixed, and put them, by degrees, into the *glaſs* at ſix times, waiting a little while between each putting in; when the whole is put in, let the *glaſs* boil and ſettle for twenty-four hours; then make a little *glaſs* body of it, which put in the furnace many times, and ſee if the *glaſs* be enough, and whether it have on the outſide veins of blue, green, red, yellow, and other colours, and have beſide theſe veins, waves, like thoſe of the chalcedonies, jaſpers, and oriental agates, and if the body kept within looks as red as fire.

When it is found to anſwer thus it is perfect, and may be worked into toys and veſſels, which will always be beautifully variegated; theſe muſt be well annealed, which adds much to the beauty of their veins. Maſſes of this may be poliſhed at the lapidary's wheel as natural ſtones, and appear very beautiful. If in the working the matter grow tranſparent, the work muſt be ſtopped, and more tartar, ſoot, and crocus martis, muſt be put to it, which will give it again the neceſſary body and opacity, without which it does not ſhew the colours well. Neri.

GLASS *reſembling the* CHRYSOLITE may be made of ten pounds of either of the compoſitions for hard *glaſs*, deſcribed above, and ſix drams of calcined iron.

GLASS reſembling the *red* CORNELIAN may be formed by adding one pound of *glaſs* of antimony, two ounces of the calcined vitriol, called *ſcarlet* OKER, and one dram of manganeſe, or magneſia, to two pounds of either of the compoſitions for hard *glaſs*. The *glaſs* of antimony and magneſia are firſt fuſed with the other *glaſs*, and then powdered and ground with the ſcarlet oker: the whole mixture is afterwards fuſed with a gentle heat, till all the ingredients are incorporated. A glaſs reſembling the white cornelian may be made of two pounds of either of the compoſitions for hard *glaſs*, and two drams of yellow oker, well waſhed, and one ounce of calcined bones. Grind them together, and fuſe them with a gentle heat.

GLASS, *emerald*. See *Green* GLASS.

GLASS, *garnet-coloured*. To give this colour to *glaſs*, the workmen take the following method. They take equal quantities of cryſtal and rochetta frit, and to every hundred weight of this mixture, they add a pound of manganeſe, and an ounce of prepared caſſer: theſe are to be powdered ſeparately, then mixed and added by degrees to the frit while in the furnace: great care is to be taken to mix the manganeſe and caſſer very perfectly; and when the matter has ſtood twenty-four hours in fuſion, it may be worked. Neri.

Glaſs of this kind may be made by adding one pound of *glaſs* of antimony, one dram of manganeſe, and the ſame quantity of the precipitate of gold by tin, to two pounds of either of the compoſitions for hard *glaſs*: or the precipitate of gold may be omitted, if the quantities of the *glaſs* of antimony and manganeſe be doubled.

GLASS, *gold-coloured*. This kind of *glaſs* may be made by taking ten pounds of either of the compoſitions for hard *glaſs*, omitting the ſalt-petre; and for every pound adding an ounce of calcined borax, or, if this quantity doth not render the *glaſs* ſufficiently fuſible, two ounces; ten ounces of red tartar, of the deepeſt colour, two ounces of magneſia, and two drams of charcoal of ſallow, or any other ſoft kind. Precipitates of ſilver baked on *glaſs* will ſtain it yellow, and likewiſe give a yellow colour on being mixed with, and melted with forty or fifty times their weight of vitreous compoſitions; the precipitate from aqua fortis, by fixed alkali, ſeems to anſwer beſt. Yellow *glaſſes* may alſo be obtained with certain preparations of iron, particularly with *Pruſſian* BLUE. But *Dr.* Lewis obſerves, that the colour does not conſtantly ſucceed, nor approach to the high yellow of gold, with ſilver or with iron. The neareſt imitations of gold which he has been able to produce, have been affected with antimony and lead. Equal parts of the *glaſs* of antimony, of flint calcined and powdered, and of minium, formed a *glaſs* of a high yellow; and with two parts of *glaſs* of antimony, two of minium, and three of powdered flint, the colour approached ſtill more to that of gold. The laſt compoſition exhibited a multitude of ſmall ſparkles interſperſed through its whole ſubſtance, which gave it a beautiful appearance in the maſs, but were really imperfections, owing to air-bubbles.

Neri directs, for a gold-yellow colour, one part of red tartar, and the ſame quantity of manganeſe, to be mixed with a hundred parts of frit. But Kunckel obſerves, that theſe proportions are faulty; that one part, or one and a quarter of manganeſe, is ſufficient for a hundred of frit; but that ſix parts of tartar are hardly enough, unleſs the tartar is of a dark red colour, almoſt blackiſh; and that he found it expedient to add to the tartar about a fourth of its weight of powdered charcoal. He adds that the *glaſs* ſwells up very much in melting, and that it muſt be left unſtirred and untouched as it ſtands in fuſion. Mr. Samuel More, in repeating and varying this proceſs in order to render the colour more perfect, found that the manganeſe is entirely uneſſential to the gold colour, and that the tartar is no otherwiſe of uſe, than in virtue of the coaly matter, to which it is in part reduced by the fire; the phlogiſton or inflammable part of the coal appearing, in ſeveral experiments, to be the direct tinging ſubſtance. Mr. Pott alſo, in his Neue Wichtige Phyſicaliſch-Chymiſche Materien, &c. printed in 1762, obſerves, that common coals give a yellow colour to *glaſs*; that different coaly matters differ in their tinging power; that caput mortuum of ſoot and lamp-black anſwer better than common charcoal; and that the ſparkling coal, which remains in the retort after the rectification of the thick empyreumatic animal oils, is one of the moſt active of theſe preparations. This preparation, he ſays, powdered, and then burnt again a little in a cloſe veſſel, is excellent for tinging *glaſs*, and gives yellow, brown, reddiſh, or blackiſh colours, according to its quantity: but the frit muſt not be very hard of fuſion; for, in this caſe, the ſtrong fire will deſtroy the colouring ſubſtance before the *glaſs* melts; and he has found the following compoſitions to be nearly the beſt; viz. ſand two parts, alkali three parts; or ſand two, alkali three, calcined borax one; or ſand two, alkali two, calcined borax one; and, though ſalt petre is hardly uſed at all, or very ſparingly, for yellow *glaſſes*, as it too much volatilizes the colouring ſubſtance; yet here for the moſt part a certain proportion of it, eaſily determined by trial, is very neceſſary; for, without it, the concentrated colouring matter is apt to make the *glaſs* too dark, and even of an opake pitchy blackneſs. It does not certainly appear that there is any material diverſity in the effects of different coals; the difference being probably owing to the different quantities of the inflammable matter, which they contain; ſo that a little more ſhall be required of one kind than of another, for producing the ſame degree of colour in the *glaſs*. Nor does the ſoftneſs or fuſibility of the frit appear to be in any reſpect neceſſary. Gold-coloured ſpangles may be diffuſed through the ſubſtance of *glaſs*, by mixing the yellow lakes with powdered *glaſs*, and bringing the mixture into fuſion. See Lewis's Com. Phil. Techn. p. 626. 229, &c.

GLASS, *green*, may be made by adding three ounces of copper, precipitated from aqua fortis, and two drams of precipitated iron to nine pounds of either of the compoſitions

fitions for hard *glaſs*. The fineſt method of giving this beautiful colour to *glaſs* is this. Take five pounds of cryſtalline metal, that has been paſſed ſeveral times through water, and the ſame quantity of the common white metal of polverine, four pounds of common polverine frit, and three pounds of red-lead; mix the red-lead well with the frit, and then put all into a pot in a furnace. In a few hours the whole maſs will be well purified; then caſt the whole into water, and ſeparate, and take out the lead; then return the metal into the pot, and let it ſtand a day longer in fuſion; then put in the powder of the reſiduum of the vitriol of copper, and a very little crocus martis, there will be produced a moſt lively and elegant green, ſcarce inferior to that of the Oriental emerald. There are many ways of giving a green to *glaſs*, but all are greatly inferior to this. Neri. See EMERALD.

GLASS, *ſea-green*. To make this colour in the *glaſs-trade*, the fineſt cryſtalline *glaſs* only muſt be uſed, and no manganeſe muſt be added at firſt to the metal. The cryſtal frit muſt be melted thus alone, and the ſalt, which ſwims like oil on its top, muſt be taken off with an iron ladle very carefully. Then to a pot of twenty pounds of this metal, add ſix ounces of calcined braſs, and a fourth part of the quantity of powdered zaffer: this powder muſt be well mixed, and put into the *glaſs* at three times, it will make the metal ſwell at firſt, and all muſt be thoroughly mixed in the pot. After it has ſtood in fuſion three hours, take out a little for a proof; if it be too pale, add more of the powder. Twenty-four hours after the mixing of the powder the whole will be ready to work, but muſt be well ſtirred together from the bottom, leſt the colour ſhould be deepeſt there, and the metal at the top leſs coloured, or even quite colourleſs. Some uſe for this purpoſe half cryſtal frit, and half rocheſter frit, but the colour is much the fineſt, when all cryſtal frit is uſed. Neri.

GLASS *for counterfeiting lapis lazuli*. See *Lapis* LAZULI.

GLASS *reſembling opal*. See OPAL.

GLASS, *purple, of a deep and bright colour*, may be produced, by adding to ten pounds of either of the compoſitions for hard *glaſs*, above deſcribed, ſix drams of zaffer and one dram of gold, precipitated by tin: or to the ſame quantity of either compoſition one ounce of manganeſe, and half an ounce of zaffer. The colour of AMETHYST may be imitated in this way. See *Ruby* GLASS.

GLASS, *red*. A blood-red *glaſs* may be made in the following manner; put ſix pounds of *glaſs* of lead, and ten pounds of common *glaſs*, into a pot glazed with white *glaſs*. When the whole is boiled and refined, add by ſmall quantities, and at ſmall diſtances of time, copper calcined to a redneſs, as much as on repeated proofs is found ſufficient; then add tartar in powder by ſmall quantities at a time, till the *glaſs* is become as red as blood; and continue adding one or other of the ingredients till the colour is quite perfect. Neri.

GLASS, *ruby*. The way to give the true fine red of the ruby, with a fair tranſparence, to *glaſs*, is as follows. Calcine in earthen veſſels gold diſſolved in aqua regia, the menſtruum being evaporated by diſtillation, more aqua regia added, and the abſtraction repeated five or ſix times, till it becomes a red powder. This operation will require many days in a hot furnace; when the powder is of a proper colour, take it out; and when it is to be uſed, melt the fineſt cryſtal *glaſs*, and purify it, by often caſting it into water; and then add, by ſmall quantities, enough of this red powder to give it the true colour of a ruby, with an elegant and perfect tranſparence. Neri. The proceſs of tinging *glaſs* and enamels, by preparations of gold, were firſt attempted about the beginning of the laſt century. Libavius, in one of his tracts, entitled Alchymia, printed in 1606, conjectures, that the colour of the ruby proceeds from gold, and that gold diſſolved, and brought to redneſs, might be made to communicate a like colour to factitious gems and *glaſs*. On this principle Neri, in his Art of *Glaſs*, dated 1611, gives the proceſs above recited. Glauber, in 1648, publiſhed a method of producing a red colour by gold, in a matter which is of the vitreous kind, though not perfect *glaſs*. For this purpoſe he ground powdered flint or ſand with four times its weight of fixed alkaline ſalt; this mixture melts in a moderately ſtrong fire, and when cold looks like *glaſs*; but, expoſed to the air, runs into a liquid ſtate. On adding this liquor to ſolution of gold in aqua regia, the gold and flint precipitate together in form of a yellow powder, which by calcination becomes purple: by mixing this powder with three or four times its weight of the alkaline ſolution of flint, drying the mixture, and melting it in a ſtrong fire for an hour, a maſs is obtained, of a tranſparent ruby colour, and of a vitreous appearance, which, nevertheleſs, is ſoluble in water, or by the moiſture of the air, on account of the redundance of the ſalt. The honourable Mr. Boyle, in a work publiſhed in 1680, mentions an experiment, in which a like colour was introduced into *glaſs* without fuſion; for, having kept a mixture of gold and mercury in digeſtion for ſome months, the fire was at laſt immoderately increaſed, ſo that the *glaſs* burnt with a violent exploſion; and the lower part of the *glaſs* was found tinged throughout of a tranſparent red colour, hardly to be diſtinguiſhed by that of rubies. See Poroſity of Bodies, in Shaw's Abridgment of Boyle's Works, vol. i. p. 459. and Appendix to the Sceptical Chymiſt.

About the ſame time Caſſius is ſaid to have diſcovered the precipitation of gold by tin, and that *glaſs* might be tinged of a ruby colour by melting it with this precipitate: though he does not appear, ſays Dr. Lewis, from his treatiſe De Auro, to have been the diſcoverer of either. He deſcribes the preparation of the precipitate, and its uſe, but gives no account of the manner of employing it, only that he ſays, one dram of gold, duly prepared, will tinge ten pounds of *glaſs*. See GOLD *precipitate with tin*.

This proceſs was ſoon after brought to perfection by Kunckel; who ſays, that one part of the precipitate is ſufficient to give a ruby colour to 1282 parts of *glaſs*, and a ſenſible redneſs to upwards of 1900 parts; but that the ſucceſs is by no means conſtant. Kunckel alſo mentions a purple-gold powder, reſembling that of Neri, which he obtained by inſpiſſating ſolution of gold to dryneſs, abſtracting from it freſh aqua regia three or four times, till the matter appears like oil; then precipitating with ſtrong alkaline ley, and waſhing the precipitate with water. By diſſolving this powder in ſpirit of ſalt, and precipitating again, it becomes, he ſays, extremely fair; and in this ſtate he directs it to be mixed with a due proportion of Venice *glaſs*.

Orchal, in a treatiſe entitled Sol ſine Veſte, gives the following proceſs for producing a very fine ruby. He directs the purple precipitate, made by tin, to be ground with ſix times its quantity of Venice *glaſs* into a very fine powder, and this compound to be very carefully mingled with the frit or vitreous compoſition to be tinged. His frit conſiſts of equal parts of borax, nitre, and fixed alkaline ſalt, and four times as much calcined flint as of each of the ſalts; but he gives no directions as to the proportion of the gold precipitate, or mode of fuſion. Heliot deſcribes a preparation, which, mixed with Venice *glaſs*, was found to give a beautiful purple enamel. This preparation conſiſts of equal parts of ſolution of gold, and of ſolution of zinc in aqua regia, mixed together, with the addition of a volatile ſalt prepared from ſal ammoniac, by quicklime, in ſufficient quantity to precipitate the two metals. The precipitate is then gradually heated, till it acquires a violet colour. However, though a purple or red colour, approaching to that of ruby, may, by the methods above recited, be baked on *glaſs* or enamels, and introduced into the maſs by fuſion, the way of equally diffuſing ſuch a colour through a quantity of fluid *glaſs*, is ſtill, ſays Dr. Lewis, a ſecret. The following proceſs for making the ruby *glaſs* was communicated to Dr. Lewis by an artiſt, who aſcribed it to Kunckel. The gold is directed to be diſſolved in a mixture of one part of ſpirit of ſalt, and three of aqua fortis, and the tin in one part of the mixture of the former of theſe acids with two of the latter. The ſolution of gold being properly diluted with water (ſee GOLD *precipitate*, &c.) the ſolution of tin is added, and the mixture left to ſtand till the purple matter has ſettled to the bottom. The colourleſs liquor is then poured off, and the purple ſediment, while moiſt, and not very thick, is thoroughly mixed with powdered flint or ſand. This mixture is well ground with powdered nitre, tartar, borax, and arſenic, and the compound melted with ſuitable fire. The proportions of the ingredients are 2560 parts of ſand, 384 of nitre, 240 of tartar, 240 of borax, 28 of arſenic, 5 of tin, and 5 of gold. Lewis's Com. Phil. Techn. p. 171. 621, &c.

GLASS *reſembling the* TOPAZ may be made by pulveriſing ten pounds of either of the compoſitions for hard *glaſs*, with an equal quantity of the *gold-coloured glaſs* being together.

GLASS, *white opake*, and *ſemi-tranſparent*, may be made by ten pounds of either of the compoſitions for hard *glaſs*, and one pound of well calcined horn, ivory, or bone; or an opake whiteneſs may be given to *glaſs*, by adding one pound of very white arſenic to ten pounds of *glaſs*. Let them be well powdered and mixed, by grinding them together; and then fuſed with a moderate fire, till they are thoroughly incorporated. A *glaſs* of this kind is made in large quantities at a manufactory in London, and uſed not only for different kinds of veſſels, but as a white ground for enamel in dial-plates and ſnuff-

boxes, which do not require finishing with much fire, because it becomes very white and fusible with a moderate heat.

GLASS, *yellow*. See *Gold-coloured* GLASS.

GLASS *balls*, which are circular or otherwise shaped hollow vessels of *glass*, may be coloured within, so as to imitate the semi-pellucid gems. The method of doing it is this: make a strong solution of ichthyocolla, or isinglass, in common water, by boiling; pour a quantity of this while warm into the hollow of a white *glass* vessel; shake it thoroughly about, that all the sides may be wetted, and then pour off the rest of the moisture. Immediately after this, throw in red-lead, shake it and turn it about, throw it into many places with a tube, and the moisture will make it stick and run in waves and pretty figures. Then throw in some of the painter's blue smalt, and make it run in waves in the ball as the red-lead; then do the same with verdigrise, next with orpiment, then with red-lake, all well ground; always calling in the colours in different places, and turning the *glass*, that the moisture within may run them into the waves. Then take fine plaster of Paris, and put a quantity of it into the ball; shake it also nimbly about; this will every where stick firmly to the *glass*, and give it a strong outer coat, keeping all the colours on very fairly and strongly. These are set on frames of carved wood, and much esteemed as ornaments in many places. Neri.

GLASS-*drops*. See RUPERT'S *drop*.

GLASS, *painting of*. See FOLIATING and LOOKING-*glass*.

GLASS, *gilding of*. See GILDING *of enamel and glass*.

GLASS, *grinding of*. See GRINDING.

GLASS *of lead*, a *glass* made with the addition of a large quantity of lead, of great use in the art of making counterfeit gems. The method of making it is this: put a large quantity of lead into a potter's kiln, and keep it in a state of fusion with a moderate fire, till it is calcined to a grey loose powder; then spread it in the kiln, and give it a greater heat, continually stirring it to keep it from running into lumps; continue this several hours, till the powder become of a fair yellow; then take it out, and sift it fines this is called calcined lead.

Take of this calcined lead fifteen pounds, and crystalline, or other frit, twelve pounds; mix these as well as possible together; put them into a pot, and set them in the furnace for ten hours; then call the whole which will be now perfectly melted, into water; separate the loose lead from it, and return the metal into the pot; and after standing in fusion twelve hours more, it will be fit to work. It is very tender and brittle, and must be worked with great care, taking it slowly out of the pot, and continually wetting the marble it is wrought upon. Neri.

It is well known, that cerusa, or white lead, minium, litharge, and all the other preparations and calces of lead, are easily fused by a moderate fire, and formed into a transparent *glass* of a deep yellow colour. But this *glass* is so penetrating and powerful a flux, that it is necessary to give it a greater consistence, in order to render it fit for use. With this view, two parts of calx of lead, e. g. minium, and one part of sand, or powdered flints, may be put into a crucible of *refractory* clay, and baked into a compact body. Let this crucible, well closed with a luted lid, be placed in a melting furnace, and gradually heated, for an hour, or an hour and a half; and afterwards let the heat be increased, so as to obtain a complete fusion, and continued in that state for the same time: let the crucible remain to cool in the furnace, and when it is broken, a very trasparent yellow-coloured *glass* will be found in it. Some add nitre and common salt to the above mixture, because these salts promote the fusion and the more equal distribution of the sand. This *glass* of lead has a considerable specific gravity, and its lowest part is always the heaviest. It is an important flux in the assays of ores to facilitate their fusifications.

Glass of lead is capable of all the colours of the gems in very great perfection. The methods of giving them are these: for green, take polverine frit twenty pounds, lead calcined fifteen pounds; sift both the powders very fine; then melt them in a *glass*, separating the unmixed lead, by casting the whole into water; repeat this twice; then add half gold yellow *glass*, and let them incorporate and purify, and they will be of the true and exact colour of the oriental topazes.

For sea-green, take crystal frit fifteen pounds, calcined lead ten pounds; mix and sift them together, and set them in a pot in a furnace; in twelve hours the whole will be melted; then cast it into water, and separate it from the loose lead; put them into the furnace again for eight hours; then separate the loose lead by washing a second time, and return it to the pot for eight hours more. Neri.

GLASS, *painting in*. The primitive manner of painting in *glass* was very simple, and of consequence very easy: it consisted in the mere arrangement of pieces of *glass* of different colours, in some sort of symmetry; and constituted a kind of what we call *MOSAIC work*.

Afterwards, when they came to attempt more regular designs, and even to represent figures raised with all the shades, their whole address went no farther than to the drawing the contours of the figures in black, with water colours, and hatching the draperies, after the same manner, on *glasses* of the colour of the object intended to be painted. For the carnations, they chose *glass* of a bright red; upon which they designed the principal lineaments of the face, &c. with black.

At last the taste for this sort of painting being considerably improved, and the art being found applicable to the adorning of churches, basilicæ, &c. they found means of incorporating the colours with the *glass* itself, by exposing them to a proper degree of fire, after the colours had been laid on.

A French painter at Marseilles is said to have given the first notion hereof, upon going to Rome, under the pontificate of Julius II. But Albert Durer, and Lucas of Leyden were the first that carried it to any height.

The colours used in painting on *glass* are very different from those used either in painting in oil or water.

The *black* is made of two thirds of flakes, or scales of iron, beaten up, and mixed with another third of rocaille, or little glass beads. *White*, with sand, or little white pebbles, calcined, pounded in a mortar, and afterwards ground on marble; with one fourth part of salt-petre added thereto, and the mixture calcined and pulverized over again; to which, when they are ready to use it, is added a little *gypsum*, or plaister of Paris well ground, &c. For *yellow*, they used leaf-silver ground, mixed up in a crucible, with sulphur, or saltpetre; then, well beaten and ground on a porphyry stone; and, at length, ground over again with nine times as much red oker. *Red* is made of litharge of silver, and scales of iron, gum Arabic, ferretta, glass-beads, and blood stone, nearly in equal quantities. This is one of the most difficult colours; and the preparation only to be learned by experience. *Green* is made of ær ustum, one ounce, as much black lead, and four ounces of white sand, incorporated by the fire. After calcination, they add a fourth part of saltpetre; after a second calcination, a sixth part more: after which they make a third coction before it is used. *Azure*, *purple*, and *violet*, are prepared like green, only leaving out the æs ustum, and in the lieu thereof using sulphur for azure; perigueux, for purple; and both these drugs for violet. *Carnations* are made of ferretta and rocaille. And lastly, colours for the hair, trunks of trees, &c. are made of ferretta, rocaille, &c.

This account of colours we have from M. Felibien's excellent work Des Principes d'Architecture, &c. though it must be owned, that all the painters on *glass* do not use them; there being few artists of that kind but have invented their own particular ones, whereof they usually make great secrets. But this is certain, that these above described are sufficient for the best paintings of all sorts; provided the person has but the skill to manage them.

In the windows of divers ancient churches, chapels, colleges, &c. we meet with the most beautiful and lively colours imaginable; such as far exceed any used among us: but it is not that the secret of making those colours is lost; but that the moderns would not go to the expence of them; nor take all the necessary pains; because this sort of painting is not now so much esteemed as formerly.

Mr. Walpole, in his Anecdotes of Painting in England, has traced the history of this art from the Reformation, when misguided zeal destroyed most of the monuments of it in our churches, through a series of professors to the present time. In Aubrey's manuscript survey of Wilts, in the library of the Royal Society, it is said, on the authority of sir W. Dugdale, that the first painted glass in England was done in king John's time: and Mr. Walpole produces instances of it in the reign of king Henry III. Among the later proficients in this art were Isaac Oliver, who painted the windows at Christ-church, Oxford in 1700. William Price, who in the same year painted the window in Merton chapel, *William* Price

Price the fon, to whofe art we owe the windows at Queen's New-college, and Mundlin, of whom Mr. Walpole fays, that his colours are fine, his drawing good, and his tafte in ornaments and Mofaic far fuperior to any of his predeceffors, and equal even to the antique. In 1761 Mr. Paterfon, an auctioneer, late of Eſex-houſe in London, exhibited the two firſt auctions of painted *glaſs* imported from Flanders; and undertook alſo to eſtabliſh a manufactory of painted *glaſs*: ſeveral of the pieces of this ingenious artiſt exhibited colours vying in perfection with the old paintings.

Thoſe beautiful works, among the painters in *glaſs*, which were made in the glaſs-houſe, were of two kinds: in ſome, the colour was diffuſed through the whole body of *glaſs*: in others, which were the more common, the colour was only on one ſide, ſcarce penetrating within the ſubſtance above one third of a line; though this was more, or leſs, according to the nature of the colour; the yellow being always found to enter the deepeſt.

Theſe laſt, though not ſo ſtrong and beautiful as the former, were of more advantage to the workmen; becauſe, on the ſame *glaſs*, though already coloured, they could ſhew other kind of colours, where there was occaſion to embroider draperies, enrich them with fallages, or repreſent other ornaments of gold, ſilver, &c.

In order to this, they made uſe of emery; grinding, or wearing down the ſurface of the *glaſs*, till ſuch time as they were got through the colour, to the clear *glaſs*: this done, they applied the proper colours on the other ſide of the *glaſs*. By this means the new colours were prevented from running, and mixing among the former, when the *glaſſes* came to be expoſed to the fire, as will hereafter be ſhewn.

When the intended ornaments were to appear white, or ſilvered, they contented themſelves to bare the *glaſs* of its colour with emery, without applying any new colour at all; and it was in this manner, that they wrought the lights and heightenings on all kinds of colours.

The painting with vitreous colours on *glaſs* depends entirely on the ſame principles as *painting in* ENAMEL; and the manner of executing it is likewiſe the ſame; except that in this the tranſparency of the colours being indiſpenſible requiſite, no ſubſtances can be uſed to form them but ſuch as vitrify perfectly: and, therefore, the great object is to find a ſet of colours, which are compoſed of ſuch ſubſtances, as by the admixture of other bodies may promote their vitrification and fuſion; are capable of being converted into *glaſs*; and melting, in that ſtate, with leſs heat than is ſufficient to melt ſuch other kinds of *glaſs* as may be choſen for the ground or body to be painted; in manner as to make them proper to be worked with a pencil; and to burn or reduce them by heat, to a due ſtate of fuſion, without injuring or melting the *glaſs* which conſtitutes the body painted.

The firſt thing to be done, in order to paint on glaſs, in the modern way, is to deſign, and even colour, the whole ſubject on paper. Then they make choice of pieces of *glaſs* proper to receive the ſeveral parts, and proceed to divide or diſtribute the deſign itſelf, or the paper it is drawn on, into pieces ſuitable to thoſe of *glaſs*: having always a view that the *glaſſes* may join in the contours of the figures, and the folds of the draperies; that the carnations, and other finer parts, may not be damaged by the lead where with the pieces are to be joined together. The diſtributer being made, they mark all the *glaſſes*, as well as papers, with letters, or numbers; that they may be known again; which done, applying each part of the deſign on the *glaſs* intended for it, they copy or tranſfer the deſign upon this *glaſs*, with the black colour, diluted in gum-water; by tracing and following all the lines and ſtrokes, as they appear through the *glaſs*, with the point of a pencil.

When theſe firſt ſtrokes are well dried, which happens in about two days, the work being only in black and white, they give it a light waſh over, with urine, gum Arabic, and a little black; and this ſeveral times repeated, according as the ſhades are deſired to be heightened: with this precaution, never to apply a new waſh, till the former is ſufficiently dried. This done, the lights and fillings are given, by rubbing off the colour in the reſpective places, with a wooden point, or the handle of the pencil.

As to the other colours above mentioned, they are uſed with gum-water, much as in painting in miniature; taking care to apply them lightly, for fear of effacing the outlines of the deſign; or even, for the greater ſecurity, to apply them on the other ſide, eſpecially yellow, which is very pernicious to other colours, by blending therewith.

And here too, as in pieces of black and white, particular regard muſt be always had, not to lay colour on colour, or lay on a new lay, till *ſuch time as the former are well dried*. It may be added, that the yellow is the only colour that penetrates through the *glaſs*, and incorporates therewith by the fire: the reſt, and particularly the blue, which is very difficult to uſe, remaining on the ſurface, or at leaſt entering very little. When the painting of all the pieces is finiſhed, they are carried to the furnace or oven, to anneal or bake the colours. The furnace here uſed is ſmall, built of brick, from eighteen to thirty inches ſquare: at ſix inches from the bottom is an aperture to put in the fewel, and maintain the fire. Over this aperture is a grate, made of three ſquare bars of iron, which traverſe the furnace, and divide it into two parts. Eight inches above this partition is another little aperture, through which they take out pieces, to examine how the action goes forward.

On the grate is placed a ſquare earthen pan, ſix or ſeven inches deep; and five or ſix inches leſs, every way, than the perimeter of the furnace. On one ſide hereof is a little aperture, through which to make the trials, placed directly oppoſite to that of the furnace deſtined for the ſame end.

In this pan are the pieces of *glaſs* to be placed in the following manner: firſt, the bottom of the pan is covered with three ſtrata, or layers of quickſilme, interſticed, thoſe ſtrata being ſeparated by two others, of old broken *glaſs*: the deſign whereof is to ſecure the painted *glaſs* from the too intenſe heat of the fire. Then come the *glaſſes* are laid horizontally on the laſt, or uppermoſt, layer of lime.

The firſt row of *glaſſes* they cover over with a layer of the ſame powder an inch deep; and over this they lay another range of *glaſſes*: and thus alternately, till the pan is quite full; taking care that the whole heap always ends with a layer of the lime-powder.

The pan thus prepared, they cover up the furnace with tiles, on a ſquare table of earthen-ware, cloſely luted all round; only leaving five little apertures, one at each corner, and another in the middle, to ſerve as chimneys.

Things thus diſpoſed, there remains nothing but to give the fire to the work. The fire for the two firſt hours muſt be very moderate; and muſt be increaſed, in proportion as the coction advances, for the ſpace of ten or twelve hours; in which time it is uſually completed. At laſt, the fire, which at firſt was only of charcoal, is to be of dry wood: ſo that the flame covers the whole pan, and even iſſues out at the chimneys.

During the laſt hours, they make aſſays from time to time, by taking out pieces laid for that purpoſe, through the little aperture of the furnace, and put, to ſee whether the yellow be perfect, and the other colours in good order. When the annealing is thought ſufficient, they proceed with great haſte to extinguiſh the fire, which otherwiſe would ſoon burn the colours, and break the *glaſſes*.

GLASS, *painting on, by means of prints*. *See* BACK-*painting*.

GLASS, *polishing of*. *See* POLISHING and GRINDING.

GLASS-*porcelain*, the name given by many to a modern invention of imitating the china-ware with *glaſs*. The method given by Mr. Reaumur, who was the firſt that carried the attempt to any degree of perfection, is delivered by that gentleman in the Memoirs of the Academy of Sciences of Paris to this effect. THE change of *glaſs* was firſt taken notice of by Neumann, who, in diſtilling milk in a *glaſs* retort obſerved, that the bottom of the veſſel acquired the appearance of porcelain, which he attributes to the fine white earthy matter of the milk forced into the *glaſs* by heat. Neum. Chem. Works by Dr. Lewis, p. 571.

The mixing *glaſs* reduced to powder, with other leſs eaſily vitrifiable ſubſtances for the forming a paſte to be afterwards made into a ſort of porcelain, has been a contrivance long practiſed, but it is very troubleſome, and the reſult ſubject to many faults; but this new ware is made of *glaſs* alone, and that with much leſs trouble, and without the reducing it to powder. By this art, veſſels of *glaſs* are changed into veſſels of a ſort of porcelain, without altering their form, and the meaneſt *glaſs* ſerves as well as the beſt for that purpoſe; our common coarſe green quart-bottles, or the great bell *glaſſes* with which gardeners cover their melons, &c. being by this means changeable into a beautiful white ſort of porcelain-ware; and this is to be done in ſo eaſy a manner, and with ſo ſmall expence, that it requires no more trouble or charge, than that of baking a common veſſel of our coarſe earthen-ware, and for this reaſon the veſſels of this ſort of ware may be afforded extremely cheap.

It is very certain, that all porcelain-ware is a ſubſtance in the ſtate of ſemivitrification; and in order to bring *glaſs*, which is a wholly vitrified ſubſtance, into the condition of porcelain, there requires no more than to reduce it to a leſs perfectly vitrified ſtate.

The queſtion which would naturally be ſtarted on this occaſion, is, whether it be poſſible to reduce *glaſs* to a leſs vitrified

sitisfied state, it having already undergone what is deemed the last change by fire. But when we consider, that the *glass* of antimony, the vitrifications of many of the metals, as the *glass* of lead, and the counterfeit gems coloured by the metals, are more or less easily reduced again by chemistry to metals, &c. the reducing of fossil, stones, &c. after they are vitrified, at least a little way back toward their native or pristine state, may appear not wholly impracticable, and the attempts which Mr. Reaumur made on this occasion, were what gave him the first hint of the *glass*-porcelain.

The method of making it is this. The *glass*-vessels to be converted into porcelain, are to be put into a large earthen vessel, such as the common fine earthen dishes are baked in, or into sufficiently large crucibles; the vessels are to be filled with a mixture of fine white sand, and of fine gypsum or plaister-stone burnt into what is called plaister of Paris, and all the interstices are to be filled up with the same powder, so that the *glass*-vessels may no where touch either one another, or the sides of the vessel they are baked in. The vessel is to be then covered down and luted, and the fire does the rest of the work: for this is only to be put into a common potter's furnace and where it has stood there the usual time of the baking the other vessels, it is to be taken out, and the whole contents will be found no longer *glass*, but converted into a white opake substance, which is a very elegant porcelain, and has almost the properties of that of China. Memoirs Acad. Sciences Par. 1739.

The powder which has served once, will do again as well as fresh, and that for a great many times: nay, it seems, even to often. The cause of this transformation, says Macquer, is probably that the vitriolic acid of the gypsum quits its basis of calcareous earth, and unites with the alkaline salt and saline earth of the *glass*, with which it forms a kind of salt or selenites, differing from the calcareous selenites, by the interposition of which matter the *glass* acquires the qualities of porcelain. Dr. Lewis, from a variety of experiments on the nature, and qualities, and method of producing this porcelain has deduced the following conclusions: 1. Green *glass* cemented with white sand received no change in a heat below ignition: in a low red-heat, the change proceeded very slowly; but in a strong red-heat, approaching to whiteness, the thickest pieces of *glass* bottles were thoroughly changed in three hours. 2. The *glass* sustained the following proportion of changes. Its surface first became blue; its transparence was diminished, and when held between the light and the eye, it appeared of a yellowish hue: afterwards it was changed a little way on both sides into a white substance, externally still bluish; and as this change advanced further and further within the *glass*, the colour of the surface part in the middle approached nearer to yellow: the white coat was of a fine porous texture, and the fibres were disposed nearly parallel to one another, and transverse to the thickness of the piece: by degrees the *glass* became throughout white and fibrous, the external blackishness at the same time going off, and being succeeded by a dull whitish or dun colour: by a still longer continuance in the fire, the fibres were changed gradually from the external to the internal part, and converted into grains; and the texture then was not unlike that of common porcelain. The grains, at first fine and somewhat glowy, appeared afterwards larger and duller, and at length the substance of the *glass* became porous and friable, like a mass of white sand slightly cohering. 3. Concerning the qualities of the converted *glass* Dr. Lewis observes, that the whiteness of the internal part was not inferior to that of porcelain, but that its surface was the least beautiful, that the thick pieces were quite opake, and that several thin pieces were faintly transparent: that while it remained in a fibrous state, its hardness became greater than that of *glass*, or of the common kinds of porcelain: it was capable of sustaining sudden changes of heat and cold better than any porcelain: and in a moderate white heat, it was fusible into a substance not fibrous, but vitreous and smooth, like white enamel: that when its texture had been strongly granulated it was now much softer and unfusible: and, lastly, that when fused entirely granulated unfusible pieces, which with the continuance of a moderate heat, would have become porous and friable, were suddenly exposed to an intense fire, they were rendered remarkably more compact than before: the solidity of some of them being superior to that of any other ware. 4. No difference appeared in the internal colour, hardness, texture, or the regular succession of changes, from the use of different cementing substances, though in external appearance the differences were considerable. All the *glass* which had been surrounded with charcoal or with soot were externally of a deep black colour, which did not disappear by exposure to a strong fire during an hour, with free access of air. Coloured clays and sands commonly red or different shades of a brown colour; and white earths gave whitish, greyish, or brownish ones. White sand, calcined flints, and gypsum gave in general the greatest whiteness, and tobacco-pipe clay the greatest glassiness, and brightness. *Glasses* compacted of earths without alkaline salt, *glass* of lead, flint-*glass*, crown-*glass*, looking-*glass* plates, a *glass* prepared with calcined flints and a fixed alkaline salt, and even green *glass* which had been fused together with a small part of alkaline salt, suffered none of the above alterations by mortification. Green bottle-*glass* and common window-*glass* were most susceptible of these alterations. 6. The changes produced by fermentation could not proceed from any absorption of matter from the cementing substance, because no increase of weight was given, and because the same changes were produced upon a piece of *glass* merely by heat, without any cementing substance. See Com. Phil. Techn. p. 250—255. See PORCELAIN.

GLASS-*pan*, the vessels in the *glass* trade used for melting the *glass*. Those for the white *glass* works are made of a tobacco-pipe clay, brought from the Isle of Wight, which is first well washed, then calcined, and afterwards ground to a fine powder in a mill; which being mixt with water, is then trod with the bare feet till lais of a proper consistence, to mould with the hands into the proper shape of the vessels. When these are thus made, they are afterwards annealed over the furnace. Those for the green-*glass* work are made of the ninth sort, and another sort of clay from Staffordshire; they make these so large as to hold three or four hundred weight of metal. And besides these, they have a small sort called pilling pots, which they set upon the larger, and which contain a finer and more nice metal fit for the nicer works. Neri.

The clay that is used for this purpose should be of the purest and most refractory kind, and well cleansed from all sandy, ferruginous, and pyritous matters; and to this it will be proper to add ground crucibles, white sand, calcined flints duly levigated, or a certain proportion of the same clay baked, and pounded not very finely. The quantity of baked clay that ought to be mixed with the crude clay, to prevent the pots from cracking when dried, or exploded in a great heat, is not absolutely determined, but depends on the quality of the crude clay, which is more or less fat. M. D'Antic, in a memoir on this subject, proposes the following method of ascertaining it: the burnt and crude clay, being mixed in different proportions, should be formed into cakes, one inch thick, and four inches long and wide. Let these cakes be slowly dried, and exposed to a violent heat, till they become as hard and as much contracted as possible, and in this state be examined; and the cake, the edges of which has suffered a diminution of its bulk equal only to an eighteenth part, is made of the best proportions. He observes, in general, that most clays acquire that the proportion of the burnt should be to the fresh as four to five.

GLASS *tubes* are of various lengths, diameters, and forms, according to the experimental purposes to which they are applied. It has been observed, that *glass* tubes laid before the fire in an horizontal position, and with their extremities supported, have had a vibratory motion about their axes, and also a progressive motion towards the fire, even when their supports are inclining from the fire, so that the tubes will move a little upwards. See Phil. Trans. N° 476, § 1.

When the progressive motion of the tube is stopped by any obstacle, its motion about its axis will still continue. When the tubes are placed in a nearly upright posture leaning to the right hand, the motion will be from east to west; but if they lean to the fire, the motion will be from west to east; and the nearer they are placed to the perfectly upright posture, the less the motion will be either way.

If the tube be placed horizontally on a *glass* plate, the fragment, for instance, of coach or crown-*glass*, instead of moving towards the fire, will move from it, and about its axis, in a contrary direction to what it had done before. Nay, it will recede from the fire and move a little upwards, when the plane inclines towards the fire.

Neither the draught of air up the chimney, nor attraction or repulsion, are the cause of these phenomena. It seems rather owing to the swelling of the tube towards the fire; for allowing such swelling, gravity must pull the tube down, when supported near its extremities horizontally; and a fresh part being exposed to the fire and swelling out again, must fall down again, and so on successively; which will produce a rotatory motion towards the fire.

If the tube be supported by two other tubes, and these be brought near to each other, and to the centre of the sup-

potted tube, then its parts hanging over on each side, being larger than the part which lies between the supporters, will, by their weight, pull downwards, and consequently force the middle part, resting upon its two props, upwards; and being less advanced towards the fire, as being less heated, will, by their oblique situation, pull the middle pair backwards also from the fire, which will cause a rotatory regressive motion, quite contrary to what the tube had when supported near its extremities. And when a single tube lies inclining opposite to the fire, either to the right hand or to the left, out of a plane perpendicular to the surface of the fire, gravity will not permit the curved part to fall, but pull it down till it coincides with a plane perpendicular to the horizon; and consequently, as new curves are generated, new motions will be to you; that is, the tube will be made to move about its axis, with this difference, when the tube inclines to the right hand, the motion will be from east to west; when to the left hand, from west to east. The fulness of this reasoning is made manifest, by bending a wire, and supporting it first near its extremities, then near its center on each side, sideways inclining it to the right and to the left; the bending in every case repeating the curved part of the tube next the fire. This solution of the phenomena is rendered the more probable from hence, that when four supporters were made use of, one at each extremity, and two near the middle, there was no motion at all, either backward or forward. Nor does the increase of contact hinder the motion, because the plane of *glass* was so broad as to have a much greater contact with the tube, and yet both the rotatory and regressive motions were manifest.

These experiments succeeded best with tubes about twenty or twenty-two inches long; the diameter about one-tenth of an inch: and they had in each a penny strung pin fixed in cork, for an axis to roll with on the supporting tubes. Phil. Trans. N° 476.

GLASS *cutters, how to remove the cracks of.* See CEMENT and RECEIVER.

GLASS, *how to take the impressions of antique gems in.* See GEM.

The property which *glass* possesses in common with other substances of being expanded by heat, and contracted by cold, wanting also observed and evinced by Mr. Hook. See Birch's Hist. of the Royal Society, vol. I. p. 411. See THERMOMETER.

GLASSES are distinguished, with regard to their form, use, &c. into various kinds, as, *drinking-glasses, optic-glasses, looking-glasses, burning-glasses*, &c.

GLASSES, *drinking*, are simple vessels of common *glass* or crystal, usually made in form of an inverted cone.

Each *glass* consists of three parts, viz. the calyx, or bowl; the bottom; and the foot; which are all wrought or blown separately.

Nothing can be more dextrous and expeditious than the manner wherein these parts are all blown: two of them opened, and all three joined together. An idea is only to be had thereof, by seeing them actually at work.

The *glasses* chiefly used in England are made of the slags of iron; crystal *glasses* being less frequent in use. The exceeding brittleness of this commodity, notwithstanding the cash rate of each *glass*, renders the consumption thereof very considerable. See the method of gilding the edges of drinking-*glass*, see GILDING *on enamel and glass*.

GLASSES, *optic*, are those made use of to strengthen, improve, or preserve the sight. See OPTIC *glasses*.

GLASSES, *convex*. See CONVEXITY.

GLASSES, *concave*. See CONCAVE.

GLASS, *inferior*. See INFERIOR.

GLASSES, *spherical*. See LENS.

GLASSES, *meniscus*. See MENISCUS, &c.

GLASSES, *plain*. See PLANE *glass*.

GLASSES, *plano-concave*. See PLANO-CONCAVE.

GLASSES, *plano-convex*. See PLANO-CONVEX.

GLASSES, *telescope*. See TELESCOPE.

GLASS, *object*. See OBJECT *glass*.

GLASSES, *eye*. See EYE *glass*.

GLASS, *magnifying*. See MAGNIFYING.

GLASS, *multiplying*. See MULTIPLYING.

GLASS, *musical*. See ARMONICA.

This method of producing musical sounds, though first introduced among us by Mr. Puckeridge, has been long since practised in Germany: and the Persians have also done the same by filling seven cups of porcelain, containing a certain quantity of water with small flicks. Encyclopedie.

GLASS, *watch*. See WATCH.

GLASS-*wort*. See KALI.

GLASS-WORT, *berry-bearing, chamæleon*, in *botany*, a genus of the *pentandria digynia* class: the characters of which are: that the calyx is three-leaved, the corolla has five petals, and the fruit is a single-headed berry.

GLASS-*wort, jointed*. See SALT-*wort*, and KELP.

GLASSY *humour*. See HUMOURS and VITREOUS.

GLASTONBURY *thorn*. See MANDRAS.

GLAUBER's *salt*. See SALT, *mineral*.

GLAUCEDO, a term used by some *medical* writers, for the disease more usually called GLAUCOMA. See CATARACT.

GLAUCIDIUM, in *Zoology*, the name used by some authors, for the smallest species of GLAUCUS, the second species of Rondeletius.

GLAUCIUM, in *Ornithology*, the name given by Belloneus to a species of DUCK, meaning by his description to be the same with the *clangula, or wild fowl from Joyce Island*, the small brown wild duck of authors.

GLAUCIUS, in *Botany*. See CELANDINE.

GLAUCOMA, Γλαύκωμα, in *Medicine*, the name of a change in the eye, wherein the crystalline humour is turned of a bluish or greenish colour, and its transparency thereby diminished.

The word comes from γλαυκὸς, *glaucus*, or *sea*, fine-green, bluish-colour, or grey-ish.

Those in whom this disorder is forming, discover it hence, that all objects appear to them as through a cloud or mist; when entirely formed, the visual rays are all intercepted, and they see nothing at all.

It is reckoned incurable, when inveterate, and in aged persons; and even under other circumstances, is very difficult of cure; externals proving of little service.

The internals best suited to it, are those wind in the gutta serena. Jul. Cæsar Claudinus, Consil. 74. gives a remedy for the *glaucoma*.

The *glaucoma* is fully distinguished from the cataract or suffusion, in that, that in the cataract the whiteness appears in the pupil, very near the cornea; but it shews deeper in the *glaucoma*.

Some late French authors, however, maintain the cataract and *glaucoma* to be one and the same disease. According to them, the cataract is not a film, or pellicle formed before the pupil, as had always been imagined; but an induration or induration of the humour itself, whereby its transparency is prevented; which brings on the cataract to the *glaucoma*. According to Mr. Sharp, the *glaucoma* of the ancient Greeks is the present CATARACT: but M. St. Yves says it is a cataract accompanied with a GUTTA *serena*.

GLAUCUS, in *Ichthyology*, the name of a genus of fishes, of which Rondeletius has described three species. The first, or most common kind, is a broad fish approaching to the figure of the turbot, but very thin; its colour on the back and sides is a sooty olive, and on the belly white, and it has on each side three or four black spots. Its scales are small and rounded, its mouth large, its teeth small, and the whole inside of its mouth tinged with blue. Its gill-fins are small, with two back fins.

The tail is extremely large, and more forked than almost in any other fish; the ends of the forks are tinged black. This is caught in the Mediterranean. Willugh. Hist. Pisc. p. 268. The second species is much of the same figure with the first, but of a smaller size, and therefore called by some *glaucidium*. This also has an undulated line, running on each side from the membrane of the gills to the middle of the body, from whence it is continued straight to the tail; whereas in the common glaucus this line runs straight all the way. The third species differs from the former in having very thin and sharp teeth, and having no side lines from the gills and is more waved. The back of these fishes is of a deep bluish hue, and below them perfectly white. Rond. de Pisc. p. 90. c. 16.

GLAUX, *sea milk-wort*, or *black-tail wort*, in *Botany*, a genus of the *pentandria monogynia* class: having a bell-leaved calyx, no corolla, and a single-celled, five valved and five-seeded capsulum. This is a low trailing perennial plant, with white flowers rising from the bosom of the leaves. It grows upon the sea shores in most parts of England, and is called the sea chick-weed.

GLAZIER, an artificer or dealer in *glass*.

GLAZING. The Roman method of *glazing* some of their urns might give our workmen a hint toward a method greatly superior to any thing now in practice for the *glazing* earthen-ware. There are a sort of red urns found in Yorkshire, which are indeed *glazed*, covered all over inside and out with a fine coal-coloured varnish, that gives

gives them a beauty, which no earthen-ware of pot-fines can attain; and is not only far more durable than our way of doing it with lead, which is apt to crack and fly, both with wet and with heat, but far more fafe and wholfome; lead being well known to be a vaporizable metal, and its fumes very noxious, there is great reafon to fufpect that it muft be unwholfome when brought to the fire. This ancient glazing leems to have been done either by the bruth, or elfe by dipping, for both the inide and outide are varnifhed with equal regularity; and fomething may be guelfed at as to the materials they ufed in it from what Pliny has left us. This author accurately obferves, that fuch earthen ware as was painted with bitumen, never loft its beauty; and after words, that it was a cuftom to cover over whole furnaces with this fort of glazing, which he obferves did not only make a ftrong coat, but fent into the matter of the ftone or earth, and therefore that could not be likely to crack and fly off like our lead-coats or glaze, for which is merely a cruft laid over them. Hook's Philof. Collect. p. 80.

A common *glazing* for any kind of earthen ware may be made of white lead forty pounds, of red-lead twenty pounds, of pearl-aflies twenty pounds, and of common falt twelve pounds. Powder the fand by grinding it, and then add it to the other ingredients and grind them together: after which range them for fome time with a moderate heat, and when the mixture is cold, pound it to powder; and when wanted for ufe temper it with water.

The preparation of thefe ingredients may be occafionally varied. We may obferve, in general, that lead ought to be excluded from the compofition of *glazings*, and other fluxes fubftituted in its ftead. See COLTON *Domeftic ren.*

A tranfparent *glazing* may be prepared, without lead, by calcining forty pounds of white fand, twenty-five pounds of pearl-aflies, and fifteen pounds of common falt; and proceeding as before: and a more perfect tranfparent *glazing* may be made of fand forty pounds, of wood-aflies, perfectly burnt, fifty pounds, of pearl-aflies ten pounds, and of common fait twelve pounds. The following receipts are taken, for the moft parts from Kunckel, who fays, that they are the true *glazings* ufed at Delft, and other Dutch manufactories.

GLAZING, *black*, is made of eight parts of red-lead, iron fcoria three, copper-afhes three, and gaffer two manganefe. This, when melted, will make a brown black; and if you want it blacker, add more gaffer to it.

GLAZING, *white*, is thus prepared: take lead-aflies, or red-lead, one pound, clear fand, or powdered flints, two pounds, common fait two pounds, white calcined tartar one pound, Venice or other glafs half a pound, nitre half a pound; mix them well together, and melt them fix feveral times, quenching them always in cold water. If you would have it fine and good, it will be proper to put the mixture into a glafs furnace for a day or two.

Another blue *glazing* may be formed of one pound of tartar, a quarter of a pound of red-lead, half an ounce of nitre, and a quarter of a pound of powdered flints, which are to be fifted and managed as in the laft receipt. Or, take two pounds of calcined lead and tin, four pounds of common fait, four pounds of powdered flints, and one pound of tartar, and Venetian glafs, each one pound. Calcine and ufe the mixture as before.

Or, again, take of red-lead, one part, of fine ftone parts, and of zaffre one part. For a violet blue *glazing*, take four ounces of tartar, two ounces of red-lead, five ounces of powdered flints, and half a dram of manganefe.

GLAZING, *brown*, is made of red-lead and flints, of each fourteen parts, and of iron fcoria two parts, fifted: or, of red-lead twelve parts, and manganefe one part, fifted. A brown *glazing*, to be laid on a white ground, may be made of manganefe two parts, and of red-lead and white glafs, of each one part, twice fifted.

GLAZING, *Spanifh-red*, is made of twelve parts of lead-aflies, and one of white glafs.

GLAZING, *yellow-colored*. To make gold-colored glazing, take of litharge three parts, of fand, or calcined flint, one part; pound, and mix them very well together; then run them into a yellow glafs with a ftrong fire. Pound this glafs, and grind it into a fubtile powder, which muft be mixed with a weft tempered fubftance of filver; make it into a pafte, which put into a crucible, and cover it with a tyeft. Give at firft a gentle degree of fire; then increafe it, and continue it till you have a glafs, which will be green. Pound this glafs again, and grind it to a fine powder; moiften this powder with fome beer, fo that by means of an hair pencil you may exprefs upon the veffels, or any piece of earthen ware. The veffels that are painted are covered over with this *glazing*, muft be firft well heated, then put under a muffle, and at fome as the glafs runs, you muft fmoak them, by holding them over burning vegetables, and take out the veffels.

Mr. Hoiftius of Peterfburg, who fent this receipt to the Royal Society, ufes the words *effere debes fumum*, which is rendered *fmoak them*, in the Tranfactions. Phil. Tranf. N° 465. § 9.

Kunckle gives fevera preparations for a gold-colored yellow *glazing*. This may be produced by fufing a mixture of three parts of red-lead, two parts of antimony, and one part of faffron of Mars; by again melting the powdered mafs, and repeating the operation four times: or, by fufing four or five times a compofition of red-lead and antimony, of each an ounce, and of fcales of iron half an ounce: or by calcining and fufing together eight parts of red-lead, fix parts of flints, one part of yellow ochre, one part of antimony, and one part of white glafs. A tranfparent gold-colored *glazing* may be obtained by twice fufing red-lead and white flints, of each twelve parts, and of fhings of iron one part.

GLAZING, *green*, may be prepared of eight parts of litharge, or red-lead, eight parts of Venice glafs, four parts of brafs-duft, or fillings of copper; or, of ten parts of litharge, twelve of flint or pebble, and one of *Sa turn*, or copper-aflies.

A fine green *glazing* may be produced by fufing one part of the Bohemian granite, one part of fhings of copper, one part of red-lead, and one part of Venetian glafs: or, by fufing one part of white glafs, the fame quantity of red-lead, and alfo of fhings of copper: powdering the mafs, and adding one part of Bohemian granite to two parts of this powder. A fine green may be obtained by mixing and grinding together any of the *prece* GLAZINGS with equal quantities of the *fame* GLAZINGS; and all the fhades and tints of green will be had by varying the proportion of the one to the other, and by the choice of the kind of yellow and blue.

GLAZING, *iron-coloring*, is prepared of fifteen parts of lead-aflies, or red-lead, fourteen of white fand, or flints, and five of calcined copper. This mixture is to be calcined and fufed.

GLAZING, *lead-coloured*, is prepared of twelve parts of litharge, eight of fait, fix of pebble or flint, and one of manganefe.

GLAZING, *purple-brown*, conffts of lead-aflies fifteen parts, clear-fand, or powdered flints, eighteen parts, manganefe one part, and white glafs fifteen meafures; to which ftome add one meafure of zaffer.

GLAZING, *red*, is made of antimony three pounds, litharge, or red-lead, three, and rud of iron, one; grind them to a fine powder. Or take two pounds of antimony, three of red-lead, and one of calcined faffron of Mars, and proceed as before.

GLAZING, *fea-green*, is made of five pounds of lead aflies, one pound of tin-aflies, three pounds of flint, three quarters of a pound of fait, half a pound of tartar, and half a pound of copper-duft.

GLAZING, *white*. A fine white *glazing* for earthen-ware is thus prepared. Take two pounds of *lead*, and one of tin; calcine them to aflies: to this take two parts, calcined flint, white fand, or broken white glafs, one part, and fait one part; mix them well together, and melt them into a cake for ufe. The trouble of calcining the tin and lead may be prevented, by procuring them in a proper ftate.

The white *glazing* for common ware is made of forty pounds of clear fand, forty-five pounds of litharge, or lead-aflies, twenty-fix of pot-aflies, and ten pounds of fait: thefe are three times melted into a cake, quenching it each time in clear cold water. Or, it may be made of fifty pounds of clear fand, feventy of lead-aflies, thirty of wood-aflies, and twelve of fait.

A very fine white *glazing* may be obtained by calcining two parts of lead, and one part of tin; and taking one part of this mafs, and of flint and common fait, of each one part, and fufing the mixture. See DELFTware.

A white *glazing* may be prepared by mixing one hundred pounds of MASTICOT, fifty pounds of red-lead, twenty pounds of calcined tin or putty, and ten pounds of common fait, and calcining and powdering the mixture feveral times.

GLAZING, *yellow*, is prepared of red-lead, three pounds; calcined antimony and tin, of each two pounds; or, according to fome, of equal quantities of the three ingredients. Thefe muft be melted into a cake, then ground fine; and this operation repeated feveral times: or, it may be made of fifteen parts of lead-ore, three parts of litharge of filver, and fifteen parts of fand.

A fine yellow *glazing* may be procured by mixing five parts of red-lead, two parts of powdered brick, one part of fand, one part of the white *glazing*, and two parts of antimony, calcining the mixture and then fufing it. Or, take four parts of white glafs, one part of antimony, three parts of red-lead and one part of iron fcales, and

fufe

fuse the mixture: or, fuse fifteen parts of flints, one part of iron-filings, and twenty-four parts of litharge. A light yellow *glazure* may be produced with ten parts of red-lead, three parts of antimony, and three of glass, and two parts of calcined tin. See *Gold-coloured* GLAZING.

GLAZING, *citron-yellow*, is made of six parts of red-lead, seven parts of fine red brick-dust, and two parts of antimony. This mixture must be calcined day and night for the space of four days, in the arch-hole of a glass-house furnace, and at last urged to fusion.

GLAZING *of Delf-ware*. See DELF-*ware*.

GLAZING *of porcelain*. See PORCELAIN.

GLAZING *of stone-ware, and pan's mass*. See POTTERY.

GLEAD, or GLADE, a name used in the northern parts of the kingdom for the *milvus* or KITE.

GLEAM is popularly used for a RAY or beam of light. Among falconers, a hawk is faid to *gleam*, when she casts or throws up flish from the gorge.

GLEANING, the act of gathering, or picking up the ears of corn left behind after the field has been reaped, and the crop carried home.

By the customs of some countries, particularly those of Melun and Eftampes, all farmers, and others are forbidden, either by themselves or servants, to put any cattle into the fields, or prevent the *gleaning* in any manner whatever, for the space of twenty-four hours after the carrying off the corn; on penalty of confiscation, &c.

GLEBA *alumi*, a name by which some call the yellowish white FELSPAR.

GLEBE, GLEBA, in *Natural History, Chemistry*, &c. a clod or piece of stone or earth, frequently containing some metal, or mineral.

The *glebes* are carried to the forges to be washed, purified, and melted, &c.

GLEBE, or GLEBE-land, is properly used for church-land. *Decretal terra ad ecclesiam pertinent.*

Gleeb-land is most commonly used for land belonging to a parish-church, beside the tithes.

Thus, Lindwood: *Glebe ad terra illa quæ exhibit decimalem; generaliter tamen dicuntur pro fide, est pro terra culta.* Though in the most general, and extensive use of the word, *glebe* is applicable to any land or ground belonging to any benefice, fee, manor, inheritance, or the like.

If any parson, vicar, &c. hath exalted any of his *glebe* lands to be manured and sowed at his own costs, with any corn or grain, the incumbents may devise all the profits and corn growing upon the said *glebe* by will. Stat. 28 H. 8. cap. 11. and if a parson fows his *glebe* and dies, the executors shall have the corn sowed by the testator. But if a *glebe* be in the hands of a tenant, and the parson dies after severance of the corn, and before his rent day; it is said, neither the parson's executors nor his successor can claim the rent, but the tenant may retain it and also the crop, unless there be a special covenant for the payment to the parson's executors proportionably, &c. Wood's Inft. 163.

GLEBE, *ecclefiaft.* In the civil law, floves were faid to be annexed to the *glebe*, i. e. they went with it, were sold with it, &c.

The right of PATRONAGE should be annexed to a *glebe*.

GLECHOMA, in *Botany*, the name by which Linnæus calls GROUND-IVY.

GLECHONITES, a name given by the ancient *Physicians*, to a fort of wine impregnated with penny-royal, much recommended in all obftructions. It takes its name from *glechon*, the Greek name of PENNY-*royal or pulegium*.

GLEDE. See GLEAD.

GLEDITSIA, in *Botany*. See HONEY *Locuft*.

GLEET, in *Medicine*, a flux of thin humour from the urethra.

A gleet, or gonorrhœa fimplex, often fucceeds the cure of a gonorrhœa virulenta; and fometimes remains obftinate, even after the ufe of a falivation.

The gleet may happen either from a too great relaxation of the glands of the urethra, or from a corrofion or exulceration of them. It appears moft frequently after a gonorrhœa has been of long ftanding, or ill managed in the cure; as by the ufe of acrid or corroding injections, and the like.

The glands may here alfo happen to be ulcerated by the matter of the running, which is often fharp and corrofive enough for that purpofe.

When the difcharge paffes very obftinate, and receives little or no check from aftringent remedies, there is ground to fufpect that it is *owing* to ulcers; but if it be inconftant and only occafional, when the patient is ftimulated by lafcivious ideas, or upon ftraining to go to ftool, it is chiefly owing to relaxation.

A *gleet* is diftinguifhed from a gonorrhœa fimplex, not only by the colour and confiftence of the matter evacuated, but alfo by the manner wherein it comes away: the matter of a *gleet* comes away at well at one time as another; but that of a gonorrhœa fimplex chiefly in erections, and when the patient goes to ftool. The matter of a *gleet* is commonly brownifh, but that of a gonorrhœa fimplex is white. Add, that the continuance of a true *gleet* is unattended with weaknefs, or other ill confequences and dangerous fymptoms; nor does it unfit men for procreation, as a gonorrhœa fimplex will.

In the cure of a *gleet* proceeding from relaxation, the principal defign is to brace and to reftore a proper degree of tenfion to the debilitated and relaxed veffels. For this purpofe, befides the medicines that are recommended in the laft ftage of the GONORRHŒA, the patient fhould have recourfe to ftronger and more powerful aftringents, as the Peruvian bark, alum, vitriol, galls, terra catechu, balauftines, &c. The bark may be communed with other medicines in the following manner: take of Peruvian bark bruifed, fix drachms; of frefh galls bruifed, two drachms; boil them in a pound and a half of water to a pound, and add to the ftrained liquor three ounces of the fimple tincture of the bark. A fmall tea-cup full of this may be taken three times a day, adding to each cup fifteen or twenty drops of the acid vitriolic vitriol. The cure may be promoted by aftringent injections, fuch as are recommended under GONORRHŒA, with the addition of a few grains of alum, or white vitriol. The cold bath fhould be conftantly ufed every morning for three or four weeks, unlefs the ufe of it be hurtful on account of the patient's full habit, which may be remedied by purging and bleeding, or an unfound ftate of the vifcera. The diet is the fame as in the laft ftage of the gonorrhœa, and the drink fhould be Spa, Pyrmont, or Briftol waters, occafionally mixed with a fmall quantity of claret or red wine. If there be reafon to apprehend, from the failure of this courfe of regimen and medicine, or other circumftances, that the *gleet* proceeds from ulcers, recourfe muft be had to mercury and fuch medicines as tend to correct any putrefcent acrimony of the juices; as the decoction of farfaparilla, faffafras, and the like. Mercurial injections have proved effectual in very obftinate cafes; and they have been recommended to be joined with terebinthinate and other aggregating medicines. Dr. Chapman recommends pills made of calomel and Venice turpentine, in the proportion of half a dram of the former to half an ounce of the latter, which may be formed into forty pills, and five or fix of them taken night and morning, accompanied with a decoction of guaiacum or farfaparilla. The laft kind of remedy prefcribed for the cure of ulcers in the urinary paffage are the BOUGIES. Buchan's Dom. Med. p. 545, &c.

GLENE, Dem. properly fignifies the cavity or focket of the EYE.

GLENE is more frequently ufed by anatomifts for the fhallower cavities of bones, into which fome other bone is received and articulated.

By which it ftands diftinguifhed *from cotyle or acetabulum*, which is a deeper cavity, intended by nature for the like purpofe.

GLENOIDES, an appellation given to the two cavities in the lower part of the firft vertebra of the neck.

The word is compofed of γλην, and ειδος, *form*.

GLESUM, or GLESSUM in *Natural Hiftory*, a name given by many of the ancients to the common yellow amber or fuccinum. The word feems to have been originally German, and to have been adopted by the Romans in their conquefts in that part of the world. They feem to have ufed the word in general for any tranfparent fubftance, and thence to have applied it to amber as a tranfparent ftone. The ifland Auftravia of the Germans, afforded a very great quantity of fine amber on its fhores, and the Roman foldiers thence gave it the name of *Glefaria*. This is a proof of the word *gleffum* being received into common ufe as the name of AMBER.

GLEUCINUM, a term ufed by the old Greek writers, to expreſs a compofition made of the oil of unripe olives, in which there were infufed fchinanth, fpikenard, and many other of the aromatic drugs, with a conſiderable quantity of muſtic: all theſe were put together into a veſſel, which was furrounded with the preſſings of grapes, the fermentation of which gave it a gentle heat, and it was left thus thirty days, being well ſtirred about every day: at the end of this time it was ſtrained off, and the clear oil reſerved for uſe. It was eſteemed warming, emollient, and relaxing, and was uſed externally in many caſes.

GLYCYRRHIZA, or GLYCYRRHIZA. See LIQUORICE.

GLINUS, in *Botany*, a genus of the *decandria pentagynia* claſs: the calyx of which conſiſts of five leaves; it has no corolla; the nectaria are formed by bifid briſtles; and the fruit is a pentangular five-celled, five-valved, poly ſpermous capſule.

GLIRES,

GLIRUS, in *Ichthyology*, a name by which Bellonius and some other authors have called a small sea fish, more commonly known by the name of the DRACUNCULUS.

GLIS. In the common acceptation of the word, this only signifies the dormouse: but Linnæus has used *glires* in a larger sense; and, in his system of Zoology, makes it the name of the fourth order of the MAMMALIA class of animals. The characters of the creatures of this class are, that they have only two fore-teeth in each jaw; they have no *dentes canini*, or dog-teeth; and the feet have toes, and are formed for leaping when they run. The animals of this class are the several species of the porcupine, the hare, the squirrel, the beaver, the mouse, and mouldwarp or American rat.

GLIS is commonly used as the name of an animal of the mouse kind, but so differently described by different authors, and so imperfectly and erroneously by many, that it is a question, whether we can properly call any known animal by the name.

Gesner, describing it by hearsay, says, that it is larger than a squirrel, and either black or brown on the back, and white on the belly; its tail short, and its general figure somewhat approaching to that of the bear. In the Linnæan system it is the grey squirrel with a white belly.

GLIS-*volans*, the *flying-dormouse*, in *Zoology*, the name of an animal, properly of the vespertilio or bat kind; it is distinguished by Linnæus by the name of *ipsoptera* or *vespertilio ocauda tus mofo folitis abcrdato*.

GLISCHROCOLOUS, an epithet used by some writers to express excrements which are at once viscid and very highly fated with gall.

GLISCHROMICTHES, in *Natural History*, the name of a genus of compound earths. The word is derived from γλισχρος, *lentus*, and μικτος, *mixed*. The bodies of this genus are loams composed of sand and a more viscid clay, and are of a tough and firm texture.

The earths of this genus are used in making bricks, and on some other occasions, and are of several distinct species.

GLISOMARGA, a word used by some authors as a name for CHALK.

GLISSA, in *Ichthyology*, the name of a sea fish of the tunny kind, but of a perfectly smooth skin, and wholly free from scales. It usually grows to the length of two cubits, and the thickness of a man's body: it is of a very round body, and has very rough jaws, but no distinct teeth; its tail is forked, but not so arched, or hunated, as that of the tunny; it lives in deep water, and is a fish of very delicate taste. Gesner. De Pisc. p. 1158.

GLISTER. See CLYSTER.

GLIZADE, in *Fencing*, is an operation performed by dexterously making your sword slip along your adversary's blade, and forming at the same time your extension, &c.

GLOBE, in *Geometry*, a round or spherical body, more usually called a SPHERE.

The earth and water together, are supposed to form a *globe*: hence called the *terraqueous globe*.

The planets, both primary and secondary, are supposed, as well as our earth, to be solid *globes*.

The earth is, in a particular sense, called the *globe*, or *globe of earth*; though it is now well known that this is not its true figure. See *Figure of the* EARTH.

GLOBE, *resistance of a*. See RESISTANCE.

GLOBE is more particularly used for an artificial sphere of metal, plaister, paper, or some other matter; on whose convex surface is drawn a map, or representation, either of the earth or heavens, with the several circles conceived thereon.

GLOBES are of two kinds, *terrestrial* and *celestial*; each of very considerable use, the one in astronomy, and the other in geography, to perform many of the operations thereof in an easy sensible manner, so as to be conceived without any knowledge of the mathematical grounds of those arts.

The fundamental parts, common to both *globes*, are an axis, representing that of the world, and a spherical shell or cover, which makes the body of the *globe*, on whose external surface the representation is drawn.

Globes, we have observed, are made of divers materials, viz. silver, brass, paper, plaister, &c. Those commonly used are of plaister and paper: the construction whereof is as follows.

GLOBES, *construction of*. A wooden axis is provided, somewhat less than the intended diameter of the *globe*; and into the extremes herein, two iron wires are driven for poles: this axis is to be the beam or basis of the whole structure.

On the axis are applied two spherical, or rather hemispherical cups, formed on a kind of wooden mould or block. These cups consist of pasteboard or paper, laid, one lay after another, on the mould, to the thickness of a crown piece; after which, having stood to dry and embody, making an incision along the middle, the two caps, thus pasted, are slipped off the mould.

They remain now to be applied on the poles of the axis, as before they were on those of the mould; and to fix them in their new place, the two edges are sewn together with packthread, &c.

The rudiments of the *globe* thus laid, they proceed to strengthen and make it smooth and regular. In order to this, the two poles are lasped in a metalline semicircle of the size intended; and a kind of plaister, made of whiting, water, and glue, heated, melted, and incorporated together, is daubed all over the paper surface. In proportion as the plaister is applied, the ball is turned round in the semi-circle, the edge whereof pares off whatever is superfluous, and beyond the due dimension, leaving the rest adhering in places that are short of it.

After such application of plaister, the ball stands to dry; which done, it is put again in the semi-circle, and fresh matter applied: thus they continue alternately to apply the composition, and dry it, till such time as the ball every-where accurately touches the semi-circle; in which state it is perfectly smooth, regular, firm, &c.

The ball thus finished, it remains to paste the map or description thereon: in order to this, the map is projected in several gores or gussets, all which join accurately on the spherical surface, and together cover the whole ball. To direct the application of these gores, lines are drawn by a semi-circle on the surface of the ball, dividing it into a number of equal parts correspounding to those of the gores, and subdividing those again answerably to the lines and divisions of the gores.

The papers thus pasted on, there remains nothing but to colour and illuminate the *globe*, and to varnish it, the better to resist dust, moisture, &c.

The *globe* itself thus finished, they hang it in a brass meridian, with an hour-circle, and quadrant of altitude, and thus fit it into a wooden horizon.

GLOBES, *description of the*. The things common to both *globes* are either delineated on the surface, or added as appendages without it.

Without the surface are, 1. The two poles, whereon the *globe* is turned, representing those of the world. See POLE. 2. The brazen meridian, which is divided into degrees, and passes through the poles. 3. The wooden horizon, whose upper side represents the horizon, and is divided into several circles; the innermost whereof contains the twelve signs of the zodiac, subdivided into their degrees; the next the Julian; and the third the Gregorian calendar: without side of all these, are drawn the points of the winds. 4. A brass quadrant of altitude, divided into 90 degrees, to be fastened on the meridian at the distance of 90 degrees from the horizon. 5. The hour-circles, divided into twice twelve hours, and fitted on the meridian round the poles, which carry an index pointing to the hour. A mariner's compass is sometimes added on the bottom of the frame, and sometimes a semi-circle of position.

On the surface are delineated, 1. The equinoctial line, divided into 360 degrees, commencing from the vernal intersection. 2. The ecliptic, divided into twelve signs, and these subdivided into degrees. 3. The zodiac. 4. The two tropics. And, 5. The polar circles. All which see under their proper articles.

What else belongs to *globes*, either as to construction or description, is different, as the GLOBE is either *celestial* or *terrestrial*.

Our common *globes*, though instructive instruments for explaining the first rudiments of geography and the spherical doctrine of astronomy, yet labour under several defects; as they do not shew how the phenomena, illustrated by them, arise from the motion of the earth, which is the principal thing beginners especially should have in view; and as they are only formed for the present age, and do not serve the purposes of chronology and history, which they might be made to do, if the poles, whereon they turn, were contrived to move in a circle round those of the ecliptic, according to its present obliquity.

Mr. John Senex, F. R. S. invented a contrivance for remedying these defects, by fixing the poles of the diurnal motion to two shoulders or arms of brass, at the distance of 23° from the poles of the ecliptic. These shoulders are strongly fastened at the other end to an iron axis, which passes through the poles of the ecliptic, and is made to move round with a very stiff motion; so that, when it is adjusted to any point of the ecliptic, which the equator is made to intersect, the diurnal motion of the *globe* on its axis will not be able to disturb it. When it is to be adjusted for any time, past or future, one of the brazen shoulders is brought under the meridian, and held fast to it with one hand, whilst the *globe* is turned about with the other, so that the point of the ecliptic which the equator is to intersect, may pass under o degrees

gree of the brazen meridian; then, holding a pencil to that point, and turning the *globe* about, it will deſcribe the equator according to its poſition at the time required; and tranſferring the pencil to 23½, and 66½ on the brazen meridian, the tropics and polar circles will be ſo deſcribed for the ſame time. By this contrivance, the celeſtial *globe* may be ſo adjuſted, as to exhibit not only the riſings and ſettings of the ſtars, in all ages and in all latitudes, but likewiſe the other phenomena that depend upon the motion of the diurnal axis round the annual axis. Senex's celeſtial *globes*, eſpecially the two greateſt, of ſeventeen and twenty-eight inches in diameter, have been conſtructed on this principle; ſo that, by means of a nut and ſcrew, the pole of the equator is made to revolve about the pole of the ecliptic. Phil. Tranſ. N° 447. p. 201, 203. or Martyn's Abr. vol. viii p. 217. and 493. art. 18. in Phil. Tranſ. vol. xlvi. p. 299.

Mr. Joſeph Harris, late aſſay-maſter of the mint, contrived to remedy the former of the defects above mentioned, by placing two horary circles under the meridian, one at each pole: theſe circles are fixed tight between two braſs collars placed about the axis, ſo that when the *globe* is turned they are carried round with it, the meridian ſerving as an index to cut the horary diviſions. The *globe*, in this ſtate, ſerves readily for ſolving problems in north and ſouth latitudes, and alſo in places near the equator; whereas, in the common conſtruction, the axis and horary circle prevent the braſs meridian from being moveable quite round in the horizon. This *globe* is alſo adapted for ſhewing how the viciſſitudes of day and night, and the alteration of their lengths, are really occaſioned by the motion of the earth: for this purpoſe, he divides the braſs meridian, at one of the poles, into months and days, according to the ſun's declination, reckoning from the pole. Therefore, by bringing the day of the month to the horizon, and rectifying the *globe* according to the time of the day, the horizon will repreſent the circle ſeparating light and darkneſs, and the upper half of the *globe* the illuminated hemiſphere, the ſun being in the zenith. Mr. Harris alſo gives an account of a cheap machine for ſhewing how the annual motion of the earth in its orbit cauſes the change of the ſun's declination, without the great expence of an orrery. Phil. Tranſ. N° 456. p. 321, &c. or Martyn's Abr. vol. viii. p. 352.

The late Mr. George Adams, mathematical inſtrument-maker to his majeſty, has made ſome uſeful improvements in the conſtruction of the *globes*. His *globes*, like others, are ſuſpended at their poles in a ſtrong braſs circle, and turn therein upon two iron pins, which are the axis. They have, beſides, a thin braſs ſemi-circle, moveable about the poles, with a ſmall, thin, ſliding circle upon it. On the terreſtrial *globe*, the thin braſs ſemi-circle is a moveable meridian, and its ſmall ſliding circle the viſible horizon of any particular place to which it is ſet. On the celeſtial *globe*, the ſemi-circle is a moveable circle of declination, and its ſmall annexed circle, an artificial ſun or planet. Each *globe* hath a braſs wire circle, placed at the limits of the twilight, which, together with the *globe*, is ſet in a wooden frame, ſupported by a neat pillar and claw, with a magnetical needle at its baſe. On the terreſtrial *globe*, the diviſion of the earth into land and water is laid down from the lateſt diſcoveries: there are alſo many additional circles, as well as the rhumb-lines, for ſolving all the neceſſary geographical and nautical problems. On the celeſtial *globe*, all the ſouthern conſtellations, lately obſerved at the Cape of Good Hope by M. de la Caille, and all the ſtars in Mr. Flamſteed's Britiſh Catalogue, are accurately laid down, and marked with Greek and Roman letters of reference in imitation of Bayer. Upon each ſide of the ecliptic are drawn eight parallel circles, at the diſtance of one degree from each other, including the zodiac: and theſe are croſſed at right angles with ſegments of great circles at every fifth degree of the eclipſe, for the more readily noting the place of the moon, or of any planet upon the *globe*. The author has alſo inſerted, from Ulugh Beigh, printed at Oxford in 1665, the Manſions of the Moon of the Arabian Aſtronomers, ſo called, becauſe they obſerved the moon to be in or near one of theſe every night during her monthly courſe round the earth, to each of which the Arabian characters are fixed. On the ſtrong braſs circle of the terreſtrial *globe*, and about 23½ on each ſide of the north-pole, the days of each month are laid down according to the ſun's declination: and this braſs circle is ſo contrived, that the *globe* may be placed with the north and ſouth poles in the plane of the horizon, and with the ſouth-pole elevated above it. The equator, on the ſurfaces of either *globe*, ſerves the purpoſe of the horary circle, by means of a ſemi-circular wire placed in the plane of the equator, carrying two indices, one of which is occaſionally to be uſed to point out the time. For a further account of theſe *globes*, with the method of uſing them, the reader may conſult Adams's Treatiſe on their Conſtruction and Uſe, &c. 1769.

GLOBE, *celeſtial*, is an artificial ſphere, on whoſe convex ſurface the fixed ſtars are laid down, at proportionable diſtances, together with the principal circles of the ſphere.

The ſurface of the celeſtial *globe* may be eſteemed a juſt repreſentation of the concave expanſe of the heavens, notwithſtanding its convexity; for if the eye were placed in the centre of it, and the *globe* made of glaſs, the ſtars that are drawn upon it would appear in a concave ſurface, exactly correſponding to thoſe in the heavens.

The uſe of theſe *globes* is to exhibit the phenomena of the motions of the ſun and ſtars, in an eaſy and obvious manner; which, though ſomewhat inaccurate, is yet exact enough for the common uſes of life, and may ſave the trouble of trigonometrical calculation.

To exhibit the ſtars, circles, &c. on the ſurface of a given ſphere or ball, and fit for the uſes of aſtronomy. 1. Aſſume any two points diametrically oppoſite to each other, as P and Q. (*Tab. Aſtronomy, fig.* 58.) and in theſe fix up axes, P A and Q C, for the ball to turn round on. The points P and Q, or A and C, will exhibit the poles of the world.

2. Divide a brazen circle A B C D into four quadrants, A E, E C, C F, and F A; and ſubdivide each quadrant into 90 degrees, numbered from the points E and F, towards the poles A and C.

3. Inciſe the *globe* in this circle, as in a meridian, at the points A and C, ſo as it may freely turn therein.

4. Apply a ſtyle or pin to the ſurface of the *globe*, in the firſt degree of the meridian, and turn the ball round; by this means will a circle be deſcribed on the ſurface repreſenting the equator to be divided into degrees.

5. From the pole of the world P towards M, and from the other pole C towards N, number 23½ degrees; the points M and N will be the poles of the ecliptic.

6. Apply a ſtyle to the meridian, in the point M, and turn the *globe* round; by this rotation will the arctic polar circle be deſcribed; and after the ſame manner is the antarctic polar to be deſcribed about the point N.

7. Number 23½ deg. from the equator towards the poles P and Q, and note the points H and I; then applying a ſtyle to the meridian, as before, two circles will be deſcribed parallel to the equator, whereof that drawn through H will be the tropic of Cancer, and the other through I the the tropic of Capricorn.

8. Hang the *globe* within the meridian, in the poles of the ecliptic, as before in the poles of the world; and applying a ſtyle to E, turn it round: by this means will the ecliptic be deliſeated, which remains to be divided into twelve ſigns; and each of theſe, again, divided into thirty degrees.

9. While the *globe* remains thus ſuſpended, bring the degree of longitude of any ſtar under the meridian; and in the meridian, number as many degrees towards the pole as is the degree of latitude of the place: the point of interſection is the place of that ſtar on the ſurface of the *globe*. After the like manner may the place of the ſtar be determined from the right aſcenſion and declination given, the *globe* being ſuppoſed ſuſpended from the poles of the world, or the equator.

10. All the ſtars of a conſtellation thus laid down, the figure of the conſtellation is to be deſigned; after which it may either be coloured or engraven.

11. Place the *globe* with the meridian, in a wooden frame or horizon, D B L, ſupported on four feet, in ſuch manner as to be divided thereby into two hemiſpheres, and that the pole A may be raiſed or depreſſed at pleaſure.

12. On the limb or edge of the horizon deſcribe a circle which divide into 360 degrees, and inſert the calendars and winds.

13. Laſtly, To the pole A fit a brazen circle, divided into twenty-four horary parts, and numbered twice twelve, ſo that the line of diviſion of XII. may be in the plane of the meridian, on either ſide the pole; and on the pole itſelf apply an index, to turn round with the *globe*. See *Horary* CIRCLE. Thus is the *globe* complete.

It may be here obſerved, that as the longitude of the ſtars is continually increaſing, a common *globe* does not remain of perpetual uſe: but the increaſe in ſeventy-two years only amounting to a degree, the whole will make no conſiderable error in a hundred years; the deſign of a *globe* being only to repreſent things ſomething near the truth.

GLOBE, *to make a celeſtial.* This method is that the moſt frequently uſed; and we only premiſed the former as being the moſt eaſily conceived, and leading more naturally to this.

1. From the given diameter of the *globe*, find a right

line

line A B, *fig.* 59. n. 2. equal to the circumference of a great circle, and divide it into twelve equal parts.

2. Through the several points of diviſion, 1, 2, 3, 4, &c. with the interval of 10 of them, deſcribe arches, mutually interſecting each other in D and E: theſe figures or pieces, duly paſted or joined together, will make the whole ſurface of the *globe*.

3. Divide each part of the right line A B into thirty equal parts, ſo that the whole line A B, repreſenting the periphery of the equator, may be divided into 360 degrees.

4. From the poles D and E, *fig.* 60. with the interval of 23½ deg. deſcribe arches *a b*; theſe will be twelfth parts of the polar circles.

5. After the like manner, from the ſame poles D and E, with the interval of 66½ deg. reckoned from the equator, deſcribe arches *c d*; theſe will be twelfth parts of the tropics.

6. Through the degree of the equator 4, correſponding to the right aſcenſion of any given ſtar, and the poles D and E, draw an arch of a circle, and taking in the compaſſes the complement of the declination from the pole D, deſcribe an arch, interſecting it in *i*; this point *i* will be the place of that ſtar.

7. All the ſtars of a conſtellation being thus laid down, the figure of the conſtellation is to be drawn according to Bayer, Hevelius, or Flamſteed.

8. Laſtly, after the ſame manner are the declinations and right aſcenſions of each degree of the ecliptic *d g* to be determined.

9. The ſurface of the *globe* thus projected on a plane is to be engraven on copper, to ſave the trouble of doing this over again for each *globe*.

10. A ball, in the mean time, is to be prepared of paper, plaiſter, &c. after the manner above directed, and of the intended diameter of the *globe*: on this, by means of a ſemi-circle and ſtyle, is the equator to be drawn; and through every 30th degree a meridian. The ball thus divided into twelve parts, correſponding to the ſegments before projected, they are to be cut from the printed paper, and paſted on the ball.

11 Nothing now remains but to hang the *globe*, as before, in a brazen meridian and wooden horizon; to which may be added, a quadrant of altitude H I, *fig.* 61. made of braſs, and divided in the ſame manner as the ecliptic and equator.

If the declinations and right aſcenſions of the ſtars be not given, but their longitudes and latitudes in lieu thereof, the ſurface of the *globe* is to be projected after the ſame manner as before; except that, in this caſe, D and E, *fig.* 59. are the poles of the ecliptic, and *f h* the ecliptic itſelf; and that the polar circles and tropics, with the equator *g d*, and the parallels thereof, are to be determined from their declinations.

One of the fulleſt catalogues of the ſtars is that of Mr. Flamſteed; wherein the right aſcenſions and declinations, as well as the longitudes, latitudes, &c. are every-where expreſſed.

GLOBE, *uſe of the celeſtial.* The uſe of this inſtrument is very extenſive; ſcarce any thing in the ſpherical aſtronomy but may be exhibited thereby.

The principal points are contained in the following problems, with their ſolution; which will let the reader enough into the nature and reaſon of this noble inſtrument, to apply it, of his own accord, in any other caſes.

To find the right aſcenſion and declination of a ſtar, repreſented on the ſurface of the globe. Bring the ſtar to the graduated ſide of the brazen meridian: then the number of degrees intercepted between the equator, and the point of the meridian cut by the ſtar, gives its declination; and the degree of the equator which comes under the meridian, together with the ſtar, is its right aſcenſion.

To find the longitude and latitude of a ſtar. Apply the centre of the quadrant of altitude over the pole of the ecliptic in the ſame hemiſphere with the ſtar, and bring its graduated edge to the ſtar: the degree on the quadrant cut by the ſtar is its latitude, reckoned from the ecliptic; and the degree of the ecliptic cut by the quadrant its longitude.

To find the ſun's place in the ecliptic. Seek the day of the month in the proper calendar on the horizon, and againſt the day in the circle of ſigns is the ſign and degree the ſun is in for that day: this done, find the ſame ſign upon the ecliptic, on the ſurface of the *globe*; this is the ſun's place for that day.

To find the declination of the ſun. The ſun's place for the day given being brought to the meridian, the degrees of the meridian intercepted between the equinoctial and that place, are the ſun's declination for that day at noon.

To find the place of a planet, with its right aſcenſion and declination; its longitude and latitude for the time being given. Apply the centre of the quadrant of altitude on the pole of the ecliptic (the pole, we mean, of the ſame denomination with the latitude), and bring it to the given longitude in the ecliptic: this point is the planet's place; and bringing it to the meridian, its right aſcenſion and declination will be found, as already ſhewn of a ſtar.

To rectify the globe, *or adjuſt it to the place, &c. ſo as it may repreſent the preſent ſtate or ſituation of the heavens.* 1. If the place be in north latitude, raiſe the north pole above the horizon; if in ſouth, raiſe the ſouth pole; till the arch intercepted between the pole and horizon be equal to the given elevation of the pole. 2. Fix the quadrant of altitude on the zenith, i. e. on the latitude of the place. 3. By means of a compaſs or meridian line, place the *globe* in ſuch a manner as that the brazen meridian may be in the plane of the terreſtrial meridian. 4. Bring the degree of the ecliptic the ſun is in to the meridian, and ſet the hour-y index to twelve: thus will the *globe* exhibit the face of the heavens for the noon of that day. 5. Turn the *globe* till the index come to any other given hour: thus will it ſhew the face of the heavens for that time.

To know all the ſtars and planets by means of the globe. 1. Adjuſt the *globe* to the ſtate of the heavens for that time. 2. Look on the *globe* for ſome one ſtar which you know; e. gr. the middlemoſt ſtar in the tail of the great bear. 3. Obſerve the poſitions of the other more conſpicuous ſtars in the ſame conſtellation; and, by tranſferring the eye from the *globe* to the heavens, you will eaſily note the ſame there. 4. After the ſame manner may you proceed from this to the neighbouring conſtellations, till you have learned them all.

If the planets be repreſented on the *globe*, after the manner above deſcribed, by comparing them with the neighbouring ſtars you will likewiſe know the planets.

To find the ſun's obliique aſcenſion, his eaſtern amplitude and azimuth, with the time of riſing. 1. Rectify the *globe* for the hour of twelve, and bring the ſun's place to the eaſtern ſide of the horizon: then the number of degrees intercepted between that degree of the equator now come to the horizon and the beginning of Aries, is the ſun's oblique aſcenſion. 2. The degrees on the horizon, intercepted between the eaſt point thereof and the point wherein the ſun is, is the ortive or riſing amplitude. 3. The hour, pointed to by the index, is the time of the ſun's riſing. 4. Turning the *globe* till the index points to the preſent hour, lay the quadrant to the ſun's place; the degree cut by the quadrant, in the horizon, is the ſun's azimuth.

To find the ſun's oblique deſcenſion, weſtern amplitude, and azimuth, with the time of ſetting. The ſolution of this problem is the ſame with that of the former; excepting that the ſun's place muſt be here brought to the weſtern ſide of the horizon, as in the former it was to the eaſtern.

To find the length of day and night. 1. Find the time of the ſun's riſing, which being numbered from midnight, the double thereof gives the length of the night. 2. Subtract the length of the night from the whole day, or twenty-four hours, and the remainder is the length of the day.

To find the riſing, ſetting, and culminating of a ſtar; its continuance above the horizon for any place and day: together with its oblique aſcenſion and deſcenſion, and its eaſtern and weſtern amplitude and azimuth. 1. Adjuſt the *globe* to the ſtate of the heavens at twelve o'clock that day. 2. Bring the ſtar to the eaſtern ſide of the horizon: thus will its eaſtern amplitude and azimuth, and the time of riſing, be found, as already taught of the ſun. 3. Bring the ſame ſtar to the weſtern ſide of the horizon: thus will the weſtern amplitude and azimuth, and the time of ſetting, be found. 4. The time of riſing, ſubtracted from that of ſetting, leaves the continuance of the ſtar above the horizon. 5. This continuance above the horizon, ſubtracted from twenty-four hours, leaves the time of its continuance below the horizon. 6. Laſtly, the hour to which the index points, when the ſtar is brought to the meridian, gives the time of its culmination.

To find the altitude of the ſun, or a ſtar, for any given hour of the day or night. 1. Adjuſt the *globe* to the poſition of the heavens, and turn it till the index point at the given hour. 2. Fix on the quadrant of altitude, at 90 degrees from the horizon, and bring it to the ſun's or ſtar's place: the degrees of the quadrant, intercepted between the horizon and the ſun or ſtar, is the altitude required.

The altitude of the ſun by day, or of a ſtar by night, being given, to find the time of that day or night. 1. Rectify the *globe* as in the preceding problem. 2. Turn the *globe* and quadrant, till ſuch time as the ſtar, or degree of the ecliptic the ſun is in, cut the quadrant in the given de-

gree

gree of altitude; then does the index point at the hour sought.

The azimuth of the sun or a star given, to find the time of the day or night. Rectify the *globe*, and bring the quadrant to the given azimuth in the horizon; turn the *globe*, till the ſtar come to the ſame: then will the index ſhew the time.

To find the interval of time between the riſings of two ſtars, or their culminations. 1. Raiſe the pole of the *globe* ſo many degrees above the horizon, as is the elevation of the pole of the place. 2. Bring the firſt ſtar to the horizon, and obſerve the time the index points to. 3. The ſame do by the other ſtar: then ſubtracting the former time from the latter, the remainder is the interval between the riſings.

After the like manner is the interval between two culminations found, by bringing both ſtars to the meridian.

The day of the month being given, to find when any ſtar will come to the meridian. Rectify for the ſun's place; turn the *globe* till the given ſtar comes to the meridian: then the index will point to the time ſought.

To find when a given ſtar will come to the meridian, at any given hour of the night. Bring the given ſtar to the meridian; ſet the index to twelve at noon; then turn the *globe* eaſtward, till the index points to an hour as far diſtant in the forenoon from twelve as the given hour is in the afternoon: obſerve the degree of the ecliptic then at the meridian, over againſt which degree, in the calendar, is the day of the month, when the given ſtar will be upon the meridian at the given hour.

To obſervation of a ſtar upon the meridian, to find the hour of the night. Rectify for the latitude and the ſun's place; bring the given ſtar to the meridian, and the index will ſhew the hour of the night.

To find the beginning and ending of the crepuſculum, or twilight. 1. Rectify the *globe*, and ſet the index to the twelfth hour, the ſun's place being in the meridian. 2. Note the ſun's place, and turn the *globe* weſtward, as alſo the quadrant of altitude, till the point oppoſite the ſun's place cut the quadrant of altitude in the eighteenth degree above the horizon: the index will then ſhew the time when the twilight commences in the morning. 3. Taking the point oppoſite to the ſun, bring it to the eaſtern hemiſphere, and turn it, till it meet with the quadrant of altitude in the eighteenth degree: then will the index ſhew the time when the twilight ends.

To explain the phenomena of the harveſt-moon by the globe. See MOON.

GLOBE, *terreſtrial*, is an artificial ſphere, on whoſe ſurface are delineated the principal places of the earth, in their proper ſituations, diſtances, &c. together with their circles imagined on the ſurface of the terreſtrial ſphere.

The uſe of the terreſtrial *globe* is to exhibit the ſeveral affections and phenomena of the different places of the earth, depending on magnitude, &c. in an eaſy, obvious manner, without the trouble of trigonometrical calculation.

GLOBE, *to conſtruct a terreſtrial.* The conſtruction of a terreſtrial *globe*, whether of metal, plaiſter, paper, &c. is the ſame as that of a celeſtial. The ſame circles are delineated on both: and as for the places, viz. cities, towns, &c. they are laid down from the longitudes and latitudes given, as the ſtars are from their right aſcenſions and declinations.

Hence all problems, depending on the circles, may be equally wrought on either *globe*; as the aſcenſions, deſcenſions, amplitudes, azimuths, riſings, ſettings, altitudes, &c. of the ſun; the lengths of day and night; hours of the day and night; crepuſcula, &c.

We ſhall here, therefore, only give what is peculiar to the terreſtrial *globe*.

GLOBE, *uſe of the terreſtrial.* *To find the longitude and latitude of any place delineated on the* globe. Bring the place to the graduated ſide of the braſs meridian: the degree of the meridian it cuts is the latitude required; and the degree of the equator, at the ſame time under the meridian, is the longitude required.

The longitude and latitude given, to find the place on the globe. Seek, in the equator, the given degree of longitude, and bring it to the meridian; then count from the equator on the meridian the degree of latitude given, towards this or that pole, as the latitude is either north or ſouth: the point under this is the place required.

The hour being given at any place, to find what hour it is in any other part of the world. Bring the given place to the meridian, and ſet the hour-index to the given hour; then by turning the *globe*, bring any place to the meridian, and the index will point to the hour of that place.

To find the antoeci, periœci, and the antipodes of any place. 1. The given place being brought to the meridian, count as many degrees on the meridian from the equator towards the other pole: the point which is thus arrived at is the place of the antoeci. 2. Note the degree of the meridian over the given place and its antoeci, and turn the *globe* till the oppoſite degree of the equator come under the meridian; or, which amounts to the ſame, till the index, which before ſtood at twelve, come to the other twelve: then will the place, correſponding to the former degree, be the periœci; and the latter, that of the antipodes.

To find what place of the earth the ſun is vertical to at any time aſſigned. 1. Bring the ſun's place found in the ecliptic to the meridian, and the index to the hour of twelve, noting what point of the meridian correſponds thereto. 2. If the given hour be before noon, ſubtract it from twelve hours, and turn the *globe* towards the weſt, till the index point at the hours remaining: thus will the place required be under the point of the meridian before noted. 3. If the hour be after noon, turn the *globe* in the ſame manner towards the weſt, till the index points at the given hour: thus, again, will the place required be found under the point of the meridian before noted.

If, at the ſame time, you note all the places which are under the ſame half of the meridian with the place found, you will have all the places to which the ſun is then in the meridian; and the oppoſite half of the meridian will ſhew all the places in which it is then midnight.

A place being given in the torrid zone, to find the two days in the year wherein the ſun is vertical to the ſame. 1. Bring the given place to the meridian, and note the degree of the meridian correſponding thereto. 2. Turn the *globe* about, and note the two points of the ecliptic paſſing through that degree. 3. Find on what days the ſun is in theſe points of the ecliptic: for on thoſe days he is vertical to the given place.

To find thoſe places in the torrid zone to which the ſun is vertical on a given day. Bring the ſun's place in the ecliptic to the meridian; then turning the *globe* round, note all the places which paſs through that point of the meridian: thoſe are the places required.

After the ſame manner may be found what people are ASCII for any given day.

The day and hour at any place being given, to find where the ſun is vertical at that hour. Bring the ſun's place to the meridian, and the degree over it is the ſun's declination at that time; then bring the given place to the meridian, and ſet the index to the given hour; turn the *globe* till the index points to twelve at noon, and the place on the *globe* which lies under the degree of the ſun's declination has the ſun then vertical.

A place being given in the frigid zone, to find the time when the ſun begins to appear above the horizon, and when it begins to diſappear; and alſo the length of the longeſt day or night in that place. Rectify for the latitude; bring the aſcending part of the ecliptic, i. e. for latitudes north of the tropic of Cancer the ſemi-circle intercepted between Capricorn and Cancer, to the ſouth point of the horizon; obſerve the degree of the ecliptic which cuts that point, and find when the ſun enters that degree, and this will give the time when the ſun begins to appear in that latitude. Bring the deſcending part of the ecliptic to the ſame point of the horizon, and the calendar will ſhew when the ſun leaves that latitude and diſappears. Again, bring the aſcending part of the ecliptic to the north point of the horizon, and the degree, as before, will ſhew in the calendar when the longeſt day begins; and by bringing the deſcending part of the ecliptic to the ſame north point, we ſhall find, in the ſame manner, when the longeſt day ends.

To find the latitude of the places wherein any given day is of any given length. 1. Bring the ſun's place for the given day to the ecliptic, and ſet the index to the hour of twelve. 2. Turn the *globe*, till the index point at the hour of riſing or ſetting. 3. Raiſe and depreſs the pole till the ſun's place appear in the eaſtern and weſtern ſides of the horizon: then will the pole be duly elevated, and, conſequently, the latitude given.

To find the latitude of thoſe places in the frigid zone where the ſun does not ſet for a given number of days. 1. Count ſo many degrees from the next tropic, towards the equinoctial point as there are units in half the number of the given days; becauſe the ſun, in its proper motion, goes nearly a degree every day. 2. Bring the point of the ecliptic, thus found, to the meridian; and its diſtance from the pole will be equal to the elevation of the pole, or latitude of the places required.

Any hour of the day or night being given, to ſhew all thoſe places to which the ſun riſes and ſets; where it is noon or midnight; and where day or night. 1. Find what place the ſun is at that time vertical to, as already taught. 2. Let this place be brought to the zenith of the wooden

horizon, i. e. elevate the pole as the latitude of that place requires: then will the places on the eaſtern ſide of the horizon beſhoſe the ſun is ſetting to; and on the weſtern ſide, thoſe he riſes to: thoſe under the upper ſemi-circle of the meridian have it noon; and thoſe under the lower, midnight. Laſtly, to thoſe of the upper hemiſphere it is day; and to thoſe in the lower, night.

Hence, as in the middle of an eclipſe, the moon is in that degree of the ecliptic oppoſite to the ſun's place; by the preſent problem it may be ſhewn what places of the earth then ſee the middle of the eclipſe and what the beginning or ending.

To find what places of the earth a planet, e. gr. the moon, is vertical to any day of the year. 1. Mark the planet's place on the *globe*, as above taught. 2. Bring this place to the meridian, and note the degree over it. 3. Turn the *globe* round, and the places which paſs under the point are thoſe required.

The declination of a ſtar, or any other phenomenon, given, to find what parts of the earth the ſame is vertical to. Count as many degrees in the meridian, from the equator towards one pole, as are equal to the given declination; viz. towards the north, if the declination be to the northward; and towards the ſouth, if the declination be ſouth. Then turning it round, the places that paſs through the extremity of this arch in the meridian are the places required.

To determine the place of the earth where any ſtar, or other celeſtial phenomenon, will be vertical at a given hour. 1. Elevate the pole according to the latitude of the place, from whoſe noon or midnight the hours are numbered. 2. Bring the ſun's place for that day to the meridian, and ſet the index at twelve o'clock. 3. Determine the place of the ſtar on the ſurface of the *globe*, and bring it to the meridian; the index will ſhew the difference of time between the impulſe of the ſun and ſtar to the meridian of the place: note the point of the meridian over the place of the ſtar. 4. Find in what places of the earth it is then noon, and ſet the index to twelve o'clock. 5. Turn the *globe* towards the weſt, till the index have paſſed over the interval of time between the culmination of the ſun and ſtar. Then, under the point of the meridian, before obſerved, will the place required be found. And hence may always be found what place a ſtar, or other phenomenon, riſes or ſets to at any given time.

To place the globe in ſuch manner, under any given latitude, as that the ſun ſhall illuminate all thoſe regions which he actually illumines on earth. 1. Rectify the *globe*, i. e. elevate the pole according to the latitude of the place; bring the place to the meridian, and ſet the *globe* north and ſouth by the compaſſes; thus, the *globe* having the ſame ſituation with regard to the ſun as the earth has, that part thereof will be illuminated which is illuminated on earth. Hence alſo the *globe* being ſituate in the ſame manner, when the moon ſhines, it will ſhew what parts are then illuminated by the moon.

And in the like manner, we may find when the ſun and moon riſe and ſet at any given time.

To find the diſtance of two places on the globe. Take the given places in the compaſſes, and apply them to the equator; the degrees which there ſubtend being reduced into miles, leagues, or the like, give the diſtances required.

The ſame may be done, and that more commodiouſly, by laying the graduated edge of the quadrant of altitude over the two places, and noting the degree intercepted.

To find how any one place bears from another. Bring one place to the meridian, and lay the quadrant of altitude over the other, and it will ſhew on the horizon the point of the compaſs on which the latter bears from the former.

To find the proportion which the land bears to the ſea. For this purpoſe Dr. Long propoſes to take the papers of a large terreſtrial *globe*, and after ſeparating the land from the ſea with a pair of ſciſſars, to weigh them carefully in ſcales. This method ſuppoſes the *globe* to be exactly delineated, and all the papers of equal thickneſs. By an experiment on the papers of Mr. Senex's ſeventeen inch *globe*, he found that thoſe comprehending the ſea weighed 349 grains, and the others only 224; whence he infers, that almoſt three fourth-parts of the ſurface of our earth between the polar circles are covered with water, and that little more than one fourth is dry land. Dr. Long omitted weighing the papers within the polar circles, becauſe the propoſition which the land bears to the ſea within them is not aſcertained. Long's Aſtron. vol. i. p. 168. See *Magnitude of the* EARTH.

GLOBE, *to conſtruct a dial by the*. See DIAL.

The *celeſtial globe* has been improved by Mr. Ferguſon: in this *globe* (ſee *Tab.* III. *Aſtronomy*, *fig.* 76) an arch MKH, of 23½, is fixed on the north pole of the axis, above the hour circle; and at the end is fixed an upright pin HG, ſtanding directly over the north pole of the ecliptic, and perpendicular to that part of the ſurface of the *globe*. On this pin are two moveable collets at D and H, to which are annexed the quadrantal wires N and O, carrying two little balls repreſenting the ſun and moon. The collet D is fixed to the circular plate F, on which are engraven the 29½ days of the moon's age, beginning under the wire N, which wire, as it turns round, carries with it the plate F. Theſe wires are fixed or ſlackened by the ſcrew G, and the two little balls are made to riſe and ſet at the ſame time and on the ſame point of the horizon, for the day to which they are rectified, as the ſun and moon do in the heavens. The ball repreſenting the moon may be ſcrewed as many degrees to either ſide of the ecliptic, as her latitude amounts to at any given time; and for this purpoſe, S is a ſmall piece of paſteboard, the curved edge of which at S is to be ſet upon the *globe* at right angles to the ecliptic, and the dark line over S to ſtand upright upon it: from this line, on the convex edge, are drawn the 5½ degrees of the moon's latitude on both ſides of the ecliptic; and when this piece is ſet upright on the *globe*, its graduated edge reaches to the moon on the wire O, by which means ſhe is eaſily adjuſted to her latitude found by an ephemeris. The horizon of this *globe* is ſupported by two ſemi-circular arches, becauſe pillars would ſtop the progreſs of the balls, when they go below the horizon in an oblique ſphere. This *globe* is rectified by elevating the pole to the latitude of the place, bringing the ſun's place in the ecliptic for the given day to the brazen meridian, and ſetting the hour-index to twelve at noon; then, ſetting the ſun directly over his place in the meridian, and the moon over her place in the ecliptic, by fixing her wire under the number that expreſſes her age for that day on the plate F; and, laſtly, laying the curved edge of the paſteboard S over the ecliptic below the moon, and adjuſting the moon to her latitude over the graduated edge of the paſteboard. Having thus rectified the *globe*, turn it round, and obſerve on what point of the horizon the ſun and moon balls riſe and ſet; for theſe agree with the points of the compaſs on which the ſun and moon riſe and ſet in the heavens on the given day; and the hour-index ſhews the times of their riſing and ſetting, and alſo the time of the moon's paſſing over the meridian. This *globe* is alſo contrived for exhibiting the phenomena of the *harveſt-*MOON, &c. Phil. Tranſ. N° 483. art. 21. in vol. xliv. p. 535, or Ferguſon's Aſtron. p. 291.

GLOBE, *dialling*. See DIALLING.

GLOBES, *patent*, are thoſe with the improvements of Mr. Neale, for which he obtained his majeſty's letters patent; by means of which he ſolves ſeveral aſtronomical problems, which do not admit of ſolution by the common *globes*.

GLOBE, *planetary*, is a machine, contrived and deſcribed by Mr. Ferguſon; in which T (ſee *Tab.* III. *Aſtronomy*, *fig.* 77) is a terreſtrial *globe* fixed on its axis ſtanding upright on the pedeſtal CDE, on which is an hour circle, having its index fixed on the axis, which turns ſomewhat tightly in the pedeſtal, ſo that the *globe* may not be liable to ſhake; to prevent which, the pedeſtal is about two inches thick, and the axis goes quite through it, bearing on a ſhoulder. The *globe* is hung in a graduated brazen meridian, much in the uſual way; and the thin plate N, NE, E, is a moveable horizon graduated round the outer edge, for ſhewing the bearings and amplitudes of the ſun, moon, and planets. The brazen meridian is grooved round the outer edge; and in this groove is a ſlender ſemi-circle of braſs, the ends of which are fixed to the horizon in its north and ſouth points: this ſemi-circle ſlides in the groove as the horizon is moved in rectifying it for different latitudes. To the middle of the ſemi-circle is fixed a pin, which always keeps in the zenith of the horizon, and on this pin the quadrant of altitude g turns; the lower end of which, in all poſitions, touches the horizon as it is moved round the ſame. This quadrant is divided into 90 degrees from the horizon to the zenithal pin on which it is turned, at 90. The great flat circle or plate A B is the ecliptic, on the outer edge of which the ſigns and degrees are laid down; and every fifth degree is drawn through the reſt of the ſurface of this plate towards its centre. On this plate are ſeven grooves, to which ſeven little balls are adjuſted by ſliding wires, ſo that they are eaſily moved in the grooves, without danger of ſtarting out of them. The ball next the terreſtrial *globe* is the Moon, the next without it is Mercury, the next Venus, the next the Sun, then Mars, then Jupiter, and laſtly Saturn; and, in order to know them, they are ſeparately ſtamped with the following characters: ☽. ☿. ♀. ☉. ♂. ♃. ♄. This plate or ecliptic is ſupported by four ſtrong wires, having their lower ends

fixed into the pedeſtal at C, D, and E, the fourth being hid by the *globe*. The ecliptic is inclined 23½ degrees to the pedeſtal, and is therefore properly inclined to the axis of the *globe* which ſtands upright on the pedeſtal.

To rectify this machine. Set the Sun, and all the planetary balls, to their geocentric places in the ecliptic for any given time, by an ephemeris: then ſet the north point of the horizon to the latitude of your place on the brazen meridian, and the quadrant of altitude to the ſouth point of the horizon; which done, turn the *globe* with its furniture till the quadrant of altitude comes right againſt the Sun, viz. to his place in the ecliptic; and keeping it there, ſet the hour-index to the XII. next the letter C.

By this machine the following problems, as well as many others, may be reſolved.

To find the amplitude, meridian altitudes, and times of riſing, culminating, and ſetting of the ſun, moon, and planets. Turn the *globe* round eaſtward, or according to the order of the ſigns; and as the eaſtern edge of the horizon comes right againſt the ſun, moon, or any planet, the hour-index will ſhew the time of its *riſing*: and the inner edge of the ecliptic will cut its riſing amplitude in the horizon. Turn on, and as the quadrant of altitude comes right againſt the ſun, moon, or planets, the ecliptic cuts the meridian altitudes in the quadrant, and the hour-index ſhews the times of their coming to the meridian. Continue turning, and as the weſtern edge of the horizon comes right againſt the ſun, moon, or planets, their ſetting amplitudes are cut in the horizon by the ecliptic; and the times of their ſetting are ſhewn by the index on the hour-circle.

To find the altitude and azimuth of the ſun, moon, and planets, at any time of their being above the horizon. Turn the *globe* till the index comes to the given time in the hour-circle; and keep the *globe* ſteady, and moving the quadrant of altitude to each planet reſpectively, the edge of the ecliptic will cut the planet's mean altitude on the quadrant, and the quadrant will cut the planet's azimuth, or point of bearing on the horizon.

The ſun's altitude being given at any time either before or after noon, to find the hour of the day, and the variation of the compaſs, in any known latitude. With one hand hold the edge of the quadrant right againſt the ſun; and, with the other hand, turn the *globe* weſtward, if it be in the forenoon, or eaſtward if it be in the afternoon, until the ſun's place at the inner edge of the ecliptic cuts the quadrant in the ſun's obſerved altitude; and then the hour-index will point out the time of the day, and the quadrant will cut the true azimuth, or bearing of the ſun for that time: the difference between which, and the bearing ſhewn by the azimuth compaſs, ſhews the variation of the compaſs in that place of the earth. Ferguſon's Aſtron. p. 297, &c.

GLOBE *amaranth*. See GOMPHRENA.

GLOBE *animalcule*, in *Natural Hiſtory*, is a ſingular, minute, aquatic animal, whoſe form ſeems exactly globular, without either head, tail, or fins. It moves in all directions, either rolling like a bowl, or gliding along ſmoothly without turning itſelf at all. Its whole body is tranſparent, except where it is covered with circular black ſpots; ſome of which have ſix or ſeven, ſome one, two, three, four, or five, and others none at all. Theſe ſpots are probably the eggs or young ones of the animal. The general appearance of the body exhibited a kind of ſhort moveable hairs or briſtles, by means of which it is conjectured the motions of the animal may be performed. Baker's Microſ. 1753, p. 322, &c.

GLOBE *crow-foot*, a *ranunculus*. See HELLEBORE.

GLOBE *daiſy*. See DAISY.

GLOBE *fiſh*, a name by which ſome ſpecies of the oſtracion are called. See OSTRACION.

GLOBE *flower*, *ſphæranthus*, in *Botany*, a genus of the *ſyngeneſia polygamia ſegregata* claſs; the characters of which are theſe: the flowers are compoſed of hermaphrodite florets and female half-florets, included in one ſcaly empalement; the hermaphrodite florets are placed in the centre; they are funnel-ſhaped, and cut into five parts at the brim, with five ſhort hair-like ſtamina, terminated by cylindrical ſummits and a germen, which decay, ſupporting a thick longer ſtyle having a ſingle ſtigma; theſe are barren: the female half-florets are ſituated round the border, and have ſcarce any petals, but an oblong germen, ſupporting a briſtly ſtyle, crowned by a double ſtigma; theſe have one oblong naked ſeed. Linnæus enumerates three ſpecies, and Miller only two, which are annual plants, that muſt be kept in a hot-bed, and, in a cold ſummer, under a glaſs caſe, in order to ripen their ſeeds in our climate.

GLOBE *thiſtle*. See *Globe* THISTLE.

GLOBULAR *chart*, a repreſentation of the ſurface, or ſome part of the ſurface, of the terraqueous globe upon a plane; wherein the parallels of latitude are circles nearly concentric; the meridians, curves bending towards the poles; and the rhumb-lines alſo curves.

The merits of this chart conſiſt in this, that the diſtances between places on the ſame rhumb are all meaſured by the ſame ſcale of equal parts; and the diſtance of any two places in the arch of a great circle, is nearly repreſented in this chart by a ſtraight line. Hence land maps, made according to this projection, would indiſputably have great advantages above thoſe made any other way. See MAP.

But for ſea charts, and the uſe of navigation, it is yet controverted, whether the *globular* chart be preferable to Mercator's, where the meridians, parallels, and particularly the rhumb-lines, are all ſtraight lines; inaſmuch as ſtraight lines are found more eaſy to draw and manage than curves, eſpecially ſuch as rhumb-lines on the *globular* chart are. This projection is not new, though not much taken notice of till of late. It is mentioned by Ptolemy, in his Geography; as alſo by Blundeville, in his Exerciſes. See CHART.

GLOBULAR *ſailing*. See *Great-circle* SAILING.

GLOBULARIA, in *Botany*. See *Blue* DAISY.

GLOBULE, GLOBULUS, a little GLOBE; otherwiſe called a *ſpherule*.

Thus the red particles of the BLOOD are called *globules* of the blood, on account of their *redneſs* and ſmallneſs. The Carteſians call the particles broken off the matter of the firſt ELEMENT, *globules of the ſecond element*. See CARTESIAN, &c.

GLOBULUS *noſe*, is uſed for the lower, flexible, cartilaginous part of the noſe.

GLOKEN-*ſpeiſſe*, in *Mineralogy*, a term uſed by the Germans to expreſs a ſort of impure regulus of biſmuth, obtained by accident, ſometimes in the making of ſmalt. The biſmuth ores are often ſo intimately mixed with the cobalt, that they cannot be ſeparated from them. In this caſe, the arſenic being raiſed in the flowers, there remains at the bottom, inſtead of the fixed vitrifiable earth of the cobalt, a ſort of impure regulus of a reddiſh colour. This is biſmuth, with an admixture of the earth of cobalt, and other extraneous matter. They ſometimes call this whole matter by the common name of *ſpeiſſe*: but more uſually they ſeparate it into two parts, and call the under part, which is moſt ſolid, *gloken-ſpeiſſe*, and the upper part they diſtinguiſh by the name of *ars caldarium*.

GLOMERELLS, in *our old Writers*, commiſſaries appointed to determine differences between ſcholars of a ſchool or univerſity, and the townſmen of a place. In the edict of the biſhop of Ely, anno 1276, there is mention of the maſter of the *glomerells*.

GLORIA *Patri*, in the Liturgy, a formula of words repeated at the end of each Pſalm, and on other occaſions, to give glory to the Trinity; called alſo the DOXOLOGY. It is thus denominated, becauſe beginning in the Latin office with theſe words, *Gloria Patri*, q. d. *Glory be to the Father*, &c.

Pope Damaſcus is commonly ſaid to have firſt ordered the rehearſal, or rather ſinging the *Gloria Patri* at the end of Pſalms. Baronius, indeed, will have it to have been uſed in the times of the apoſtles: but its uſe, then, he allows to have been more obſcure, and that it did not become popular till after the riſe of Arianiſm, when it was made a kind of ſymbol of orthodoxy.

The fifth canon of the council of Vaiſon, held in 529, decrees, "that the name of the pope ſhall always be "rehearſed in the churches of France, and after the "*Gloria Patri* ſhall be added *ſicut erat in principio*, as is "done at Rome, in Africa, &c. on account of the he-"retics, who ſay, that the Son of God had his begin-"ning in time." Fleury.

GLORIA *in excelſis* is alſo a kind of hymn rehearſed in divine ſervice, beginning with the words *Gloria in excelſis Deo, & in terra pax hominibus*, &c. *Glory be to God on high, on earth peace*, &c.

GLORIOSA, in *Botany*. See *Superb* LILY.

GLOSS, GLOSSA, a comment on the text of any author, to explain his ſenſe more fully and at large, whether in the ſame language, or in any other. See COMMENTARY.

The word, according to ſome, comes from γλωσσα, *tongue*; the office of a *gloſs* being to explain the text, as that of the tongue is to diſcover the mind. Others derive it from the Latin *glos*, or γλως, *a ſiſter-in-law*, which, among lawyers, ſometimes ſtands for ſiſter; the *gloſs* being, as it were, ſiſter to the text.

Nic. de Lyra compoſed a poſtil or *gloſs* on the Bible, in ſix volumes folio. The French ſay, proverbially of an ill comment, that it is *gloſe d'Orleans, plus obſcure que le texte*.

GLOSS is alſo uſed for a literal tranſlation, or an interpre-

tation of an author in another language, word for word. Young scholars need an interlineary *gloss* for the understanding of Juvenal, Horace, Sallust, Perſius, &c.

GLOSS is alſo uſed in matters of *Commerce*, &c. for the luſtre of ſilk, fluff, or the like.

GLOSSARY, GLOSSARIUM, a kind of dictionary for explaining the obſcure, ancient, and barbarous words and phraſes of an altered, corrupted, or refined language.

Spelman's *Gloſſary*, intitled Archaiologicum, is an excellent work; though that author did not begin to ſtudy in this way till fifty years of age. M. Da-Cange's Latin *Gloſſary* in three volumes, and his Greek *Gloſſary* in two volumes folio, are excellent performances, full of uncommon erudition. Lindenbrock has a *Gloſſary* on the laws of Charlemagne, &c.

GLOSSOCATOCHOS, a word uſed by ſome writers to expreſs a chirurgical inſtrument, uſed to depreſs the tongue for examining the mouth. See GLOSSOSPATHA.

GLOSSOCOMON, a ſurgeon's inſtrument, anciently uſed in ſetting broken and diſlocated thighs and legs; as alſo in extending thoſe which remained too ſhort after ſetting. The word is formed of γλωσσα, *tongue*, and κομεω, *to take care*; and was properly and primarily given by the ancients to a little box, wherein they kept the reeds of their hautbois, &c.

The *gloſſocomin* is deſcribed as conſiſting of a hollow trunk, wherein the thigh or leg is laid; at the bottom hereof is a kind of wheel; and towards the top are two pullies on each ſide. Several thongs of leather are tied both above and below the fractured place: thoſe below are faſtened to the axis of the wheel, which they are near; thoſe above go over the pullies to come to the axis, which they are likewiſe faſtened to: ſo that the ſame turning of the wheel both draws the part of the leg or thigh, which is above the fracture, upwards; and that below, downwards.

GLOSSOCOMON, in *Mechaniet*, is a name given by Hiero, to a machine compoſed of divers dented wheels, with pinions ſerving to raiſe huge burdens.

GLOSSOGRAPHE, in *Botany*, a name uſed by ſome authors for the *fumaria*, or common FUMITORY.

GLOSSOIDES, in *Natural Hiſtory*, a name given by ſome authors to a ſpecies of ſtone, reſembling the figure of the human tongue. This is a mere accidental configuration of a common flint or pebble, perfectly indeterminate in ſize and colour, and owing its form to no animal mould, as the ſtones found in ſhells uſually do, but is a mere *lusus naturæ* in the concretion of the ſtone.

GLOSSOPETRA, or GLOTTOPETRA, in *Natural Hiſtory*, a kind of extraneous foſſil, ſomewhat in form of a ſerpent's tongue; frequently found in the iſland of Malta, and divers other parts. See *Tab. Foſſils, cloſ. 8.*

Naturaliſts have been much divided as to the nature and origin of theſe bodies. Steno, De Corpore ſolido intra ſolidum Contento; Ol. Wormius, Differt. de *Gloſſopetris*; and Reyſchius, De *Gloſſopetris* Lunebergenſibus, treat of them at large.

The vulgar notion is, that they are the tongues of ſerpents petrified; and hence their name, which is a compound of γλωσσα, *tongue*, and πετρα, *ſtone*. Hence, alſo, their traditionary virtue in curing the bites of ſerpents.

The general opinion of naturaliſts is, that they are the teeth of fiſhes, left at land by the waters of the deluge, and ſince petrified.

They even ſpecify the very kind of fiſh, and take it to be that which Theophraſtus and the Greek writers call καρχαρίας, and the moderns the *ſhark*, or *ſea-dog*.

Camerarius cannot perſuade himſelf that the *gloſſopetræ* found in England, Malta, and round Montpelier, were ever the teeth of a ſea-dog, or any other fiſh. The chief difficulty, he ſuggeſts, is the ſmall quantity of volatile ſalt and oil which they afford by diſtillation. To which Dr Woodward anſwers, in defence of the common ſyſtem, that having lain ſo long buried under ground, it is no wonder they ſhould have loſt the beſt part of their volatile principles. It is certain, that human bones and ſkulls, long interred, do not afford near the quantity of thoſe principles that they would have done immediately after the perſon's death.

Another ſcruple, propoſed by Camerarius, is, that the *gloſſopetræ*, when expoſed to the naked fire, turn to a coal, and not to a calx; contrary to what is aſſerted by Fabius Columna. Dr. Woodward anſwers, that it is likely enough the *gloſſopetræ*, in burning, may aſſume the form of a coal, before it arrive to that of a calx.

The ſeveral ſizes of the teeth of the ſame ſpecies, and thoſe of the ſeveral different ſpecies of ſharks, afford a vaſt variety of theſe foſſil ſubſtances. Their uſual colours are black, blueiſh, whiteiſh, yelloweiſh, or brown; and in ſhape, they uſually approach to a triangular figure. Some of them are ſimple; others are triculpidate, having a ſmall point on each ſide of the large one: many of them are quite ſtrait, but they are frequently found crooked, and bent in all directions; many of them are ſerrated on their edges, and others have them plain: ſome are undulated on their edges, and ſlightly ſerrated on theſe undulations. They differ alſo in ſize as much as in figure; the larger being four or five inches long, and the ſmaller of leſs than a quarter of an inch.

They are moſt uſually found with us in the ſtrata of blue clay, though ſometimes alſo in other ſubſtances, and are frequent in the clay-pits of Richmond and other places.

They are very frequent alſo in Germany, but no where ſo plentiful as in the iſland of Malta.

The Germans attribute many virtues to theſe foſſil teeth; they call them cordials, ſudorifics, and alexipharmics: and the people of Malta, where they are extremely plentiful, hang them about their children's necks to promote dentition. They may poſſibly be of as much ſervice this way as an anodyne necklace; and if ſuſpended in ſuch a manner, that the child can get them to its mouth, may, by their hardneſs and ſmoothneſs, be of the ſame uſe as a piece of coral. See SERPENT's *Tongues*.

GLOSSO-PHARYNGÆI, in *Anatomy*, are fibres which run along the lateral edges of the tongue, from which they are parted backward, and run down on the ſides of the pharynx under the *Stylo-pharyngæi*.

GLOSSO-STAPHYLINI, in *Anatomy*, are two ſmall muſcles fixed each in the lower and lateral part of the baſis of the tongue, from whence they run up obliquely backward along the anterior half arches of the ſeptum palati, and terminate inſenſibly on each ſide near the uvula.

Mylo-GLOSSI and *Stylo*-GLOSSI. See MYLO-*gloſſi* and STYLO-*gloſſi*.

GLOSSOSPATHA, in *Surgery*, an inſtrument, called by ſome *ſpeculum linguæ*, and uſed to depreſs the tongue, in order to look into the fauces.

There are many inflammatory diſorders of the mouth, fauces, and palate, which require a depreſſion of the tongue, while they are inſpected and treated with proper remedies. The handle of a ſilver ſpoon is made to ſupply the place of this inſtrument in moſt caſes, and anſwers the purpoſe very well. Whichever is uſed, care ſhould be taken to depreſs very gently, to avoid giving the patient pain, as alſo to avoid irritating the mouth and inflamed parts.

When injections are to be made into the mouth, this inſtrument or the ſpoon ſhould alſo be applied, and the ſyringe ſhould be conveyed into the mouth over it.

GLOTTIS, in *Anatomy*, a cleft or chink in the larynx, ſerving for the formation of the voice.

The *glottis* is in form of a little tongue, whence its name, from γλωττα, *tongue*. For the ſame reaſon, the Latins call it *lingula*, i. e. *little tongue*.

Through this chink the air deſcends and aſcends in reſpiring, ſpeaking, ſinging, &c. It has an apparatus of muſcles, whereby we contract and enlarge it; and hence all the variety of tones in the voice.

The *glottis* is covered and defended with a thin, ſoft cartilage, called the *epiglottis*.

GLOTTIS, in *Ornithology*, a name given by many authors to a bird of the long-legged kind, approaching to the nature of our red ſhank, but larger and longer legged, and generally known by the name LIMOSA.

GLOVE, *chirotheca*, a habit or covering for the hand and wriſt, uſed both for warmth, decency, and as a ſhelter from the weather.

Gloves are diſtinguiſhed, with reſpect to commerce, into leather *gloves*, ſilk *gloves*, thread *gloves*, cotton *gloves*, worſted *gloves*, &c.

There are alſo *gloves* of velvet, ſattin, taffety, &c. Leather *gloves* are made of ſhamoy, kid, lamb, doe, elk, buff, &c. There are, alſo, perfumed *gloves*; waſhed, glazed, waxed *gloves*; and white, black, ſnuff-colour, &c. *gloves*; ſingle, lined, topped, laced, fringed with gold, ſilver, ſilk, fur, &c.

It is a proverb, for a *glove* to be good and well made, three kingdoms muſt contribute to it; Spain to dreſs the leather, France to cut it, and England to ſew it. But, of late, the French ſeem to have appropriated the functions of the other two; the *gloves* of the French manufacture being now ſaid to have the advantage, in point of dreſſing and ſewing, as much as of cutting.

To throw the GLOVE was a practice or ceremony very uſual among our fore-fathers, being the challenge whereby another was defied to ſingle combat. It is ſtill retained at the coronation of our kings, when the king's champion caſts his *glove* in Weſtminſter-hall.

Favyn ſuppoſes the cuſtom to have aroſe from the eaſtern nations, who in all their ſales and deliveries of lands, goods, &c. uſed to give the purchaſer their *glove* by way of livery or inveſtiture. To this effect he quotes Ruth iv. 7. where the Chaldee paraphraſe calls *glove* what the common

common version renders by *shoe*. He adds, that the rabbins interpret by *glove*, that paſſage in the cxiiith Pſalm, *In Idumæam extendam calceamentum meum. Over Edom will I caſt out my ſhoe.* Accordingly, among us, he who took up the *glove*, declared thereby his acceptance of the challenge; and as part of the ceremony, continues Favyn, took the *glove* off his own right-hand, and caſt it upon the ground, to be taken up by the challenger. This had the force of a mutual engagement on each ſide to meet at the time and place which ſhould be appointed by the king, parliament, or judges.

The ſame author aſſerts, that the cuſtom which ſtill obtains of bleſſing *gloves*, in the coronation of the kings of France, is a remain of the eaſtern practice of giving poſſeſſion with the *glove*. Lib. xvi. p. 1017, &c.

The delivery of a *glove* was in frequent uſe formerly, as a ſymbol of inveſtiture. See Du-Cange, Gloſſ. Lat.

Gloves was alſo uſed to ſignify the ſteward's or bailiff's fee, or part of the price of the inveſtiture or purchaſe-money of the land. *Si aliquam terræ partem vendere contigerit, domini conditiones habebunt: ſcilicet, tot denarios quot venditor inde habuerit ſolidos. Alioquin vero terræ illius pro* wantis *accipient duos denarios.* Where *wantis* ſignifies *gloves*, or, in French, *gants*.

Hence the common cuſtom, in many bargains, of giving ſervants money for a pair of *gloves*.

Anciently it was prohibited the judges to wear *gloves* on the bench; and at preſent, in the ſtables of moſt princes, it is not ſafe going in without pulling off the *gloves*.

GLOUTTUS, in *Anatomy*, a name given by Riolan, and ſome others, to the muſcles of the thigh, generally called *glutæi*, or ſingly *glutæus major*, &c.

GLOW-*worm*, *cicindela*, in *Zoology*, a genus of inſects of the *coleoptera* order; the antennæ of which are cetaceous, the jaws prominent and dentated, the eyes in a ſmall degree prominent, the thorax of a roundiſh marginated figure.

Cantharis and *cincindela* have been often uſed, indiſcriminately, for the *glow-worm*; but they form two diſtinct genera of the ſame order, comprehending ſeveral ſpecies, in the Linnæan ſyſtem. The ſpecies of the *cantharis* have ſetaceous antennæ; the thorax is marginated and ſhorter than the head, the exterior wings are flexile, and the ſides of the abdomen are plicated and papilloſe. In moſt ſpecies the thorax is flatted, but in ſome roundiſh. Of this genus Linnæus reckons twenty-ſix ſpecies. See CANTHARIDES. Of the *cincindela* he enumerates fourteen ſpecies, diſtinguiſhed by their colour and the ſpots on their exterior wings: thus, the field or green *glow-worm* hath five white ſpots on theſe wings: the black *glow-worm*, that frequents woody places, two; the braſſy *glow-worm*, common in moiſt places, has broad excavated ſpots on the wings; the black *glow-worm*, with a round thorax, common in rocky places, has two ſerrugineous ſpots, &c.

The male and female differ greatly in this ſpecies of inſect. The male has wings, and is a ſmall fly; the female has no wings, but is a large crawling worm.

The body of the male is oblong, and ſomewhat flatted; the wings are ſhorter than the body; the head is broad, dun, and flat; the eyes are large and black. This has no light iſſuing from it, and is not commonly ſuppoſed to beat all of kin to the *glow-worm*.

The female is what we expreſly call by this name: this is a very ſlow-paced animal, without wings, and ſomewhat reſembling a caterpillar; the head is ſmall, flat, hard, and black, and ſharp towards the mouth; it has ſhort antennæ, and ſix moderately long legs; the body is flat, and is compoſed of twelve rings, whereas the body of the male conſiſts only of five; it is of a duſky colour, with a ſtreak of white down the back. It is often ſeen in the day-time, but is not known except in the dark: at which time it is eaſily diſtinguiſhed by the glowing light, or lambent flame, that is ſeen near the tail, iſſuing from the under part of the body.

The common *glow-worm* is frequently met with under our hedges, and, if carefully taken up, may be kept alive many days on freſh turfs of graſs; all which time it will continue to ſhine in the dark.

The light of this little inſect is ſo ſtrong, that it will ſhew itſelf through ſeveral ſubſtances, in which the creature may be put up; a thin pill-box eaſily ſhews it through, and even though lined with paper, the light is not impeded in its paſſage by both. The creature is ſluggiſh, and appears dead in the day time, and its light is not diſtinguiſhable, even if carried into a darkened room, unleſs the creature be turned upon its back, and diſturbed, ſo as to be put in motion, and then it is but very faint: after ſun-ſet the light begins to return, and with it the life and motion of the animal. The motion and light of this creature ſeem, in ſome meaſure, to depend upon one another: it never ſhines but when its body is in ſome ſort of motion; and when it ſhines moſt, the body is extended to one third more than its length in the day-time. In the time of brighteſt ſhining, it will ſometimes on a ſudden turn its body about, and the light will not be larger than the head of a pin; and, on being touched, ſhe will then immediately extend herſelf, and the light will become as large and bright as ever. Phil. Tranſ. N° 71. The whole inſect is uſed in medicine, and recommended by ſome againſt the ſtone. Cardan aſcribes an anodyne virtue to it.

GLOW-*worm*, *flying*, *cicindela volans*. In the warmer months of the year, this creature is ſometimes caught in our houſes flying to the flame of a candle, and when examined in the dark, it is found luminous at theſe times, though perhaps leſs, or not at all ſo, at others; which may be a reaſon of its not being known, though caught in the fields: and to this it may be owing, that many who have deſcribed it have thought it not a native of England. See *Tab. of Microſcopical Objects*, *claſs* v. Without wings it is frequently enough found in form of the common *glow-worm*, and then always ſhines. Aldrovand has very well deſcribed the *cicindela volans*, and ſays, that it lays eggs which hatch into ſmall worms, and that theſe after a time become flies, by the ſame ſort of change which happens to caterpillars and other reptiles which become butterflies, and other ſpecies of winged inſects. Mouffet, and Thomas Bartholine, both deſcribe the animal much as Aldrovand has done, but they allow only the male to have wings; but Julius Scaliger contradicts this, and ſays, that he has caught them both winged in the act of generation: this is a plain proof that both ſexes are winged; yet it has not happened that both ſexes have been acknowledged to be ſo, even by thoſe who have quoted this paſſage. And Mr. Waller, who gives an account of them in the Philoſophical Tranſactions, obſerved them in the ſame manner in the act of copulation both winged, and with no other difference between them but that the female was the larger of the two, which is the caſe in regard to many inſects. Julius Scalig. Exerc. 191. Phil. Tranſ. N° 167. p. 841.

The male and female in this winged ſtate both ſhine in hot weather, and their light is ſo vivid as to be eaſily ſeen even while there is a candle in the room: the vibrations of it are irregular, and its colour greeniſh. The luminous parts are two ſmall ſpecks under the tail at the end, and the light continues in theſe ſome time after the tail is cut off, but then gradually goes out.

The parts of inſects continue alive in ſome degree for a conſiderable time after they are cut off, and probably the light in the tail of this animal continues juſt as long as that ſort of life remains in it. Mouffet, cap. 15.

The uſe of this light ſeems to be to direct the animal in its courſe, and in the taking of its prey, and to this purpoſe it is admirably placed. The tail is eaſily bent under the belly, and then throws the light full upon any object about, or under the head of the animal, and the eyes are placed not on the upper part, but on the under ſide of the head; ſo that they have all the advantages of it, while the light in this part is not offenſive to the eyes, as it naturally would have been if carried before the head. The creature can, upon occaſion, cover this light ſo as not to be known, or purſued by it, by its enemies. Thomas Bartholi. De Luce Anim. lib. ii. cap. 12.

This inſect is of the beetle kind, of a brown and duſky colour. It has hard caſe or ſhell-wings, as the other beetles have, and when theſe are expanded, there appear a pair of very large membranous ones; its head is covered with a ſort of ſhield or broad-brimmed hat: under this hat are placed the eyes, which are black and large, and are moveable, ſo that the creature can, upon occaſion, thruſt them forward: it has two hairy antennæ, and ſix legs are like thoſe of the common fly, hard, ſhelly, and hairy. Its eyes afford an elegant object for the microſcope, being compoſed of an infinite number of lenſes, as thoſe of the fliesbe and other inſects. Aldrovand. De Inſect. lib. i. cap. 8.

GLUE, GLUTEN, a viſcid, tenacious matter, ſerving as a cement to bind or connect divers things together.

There are divers kinds of *glues* made uſe of in the divers arts; as the *common glue*, *glover's glue*, *parchment glue*: but the two laſt are more properly called SIZE.

The *common* or *ſtrong* GLUE is a commodity uſed by numerous kinds of artificers: as joiners, cabinet-makers, caſe-makers, hatters, book-binders, &c. and the conſumption thereof is very conſiderable. The beſt is that made in England, in ſquare pieces, of a ruddy brown colour: Flanders *glue* is held the next after the Engliſh.

Glue is made of the ſkins of all kinds of beaſts; as oxen, cows, calves, ſheep, &c. The older the beaſt is, the better is the *glue* that is made of its hide. Indeed, it is rare they uſe whole ſkins for this purpoſe; thoſe being

capable

capable of being applied to better purposes: but they make use of the shavings, parings, or scraps thereof; and sometimes they make it of the feet, sinews, nerves, &c. of beasts.

That made of whole skins is the best; and that of sinews, &c. the worst: and hence, chiefly, arises the difference of *glues*, and the advantage of English and Flemish *glues*.

GLUE, *method of making*. To make *glue* of parings, they first steep them two or three days in water; then washing them well out, they boil them to the consistence of a thick jelly; this done, they pass the jelly, while yet hot, through osier baskets, to separate from it any impurities; and, in order to purify it still farther, they let it rest some time. When the ordures, or foreign matters, are precipitated to the bottom of the vessel, they melt and boil it a second time.

This done, they pour it into flat frames, or moulds; whence it is taken out, when pretty hard and solid, and then cut into square pieces or cakes. Nothing new remains but to dry it in the wind, on a sort of coarse net, and afterwards to string it to finish the drying.

The *glue* made of feet, sinews, &c. is managed after the same manner, with this only difference, that they bone and scour the feet, and do not lay them to steep.

The best *glue* is that which is oldest: the surest test of its goodness is, to lay a piece to steep three or four days in water; if it swell considerably without melting, and, when taken out, resume its former dryness, it is excellent.

GLUE, *best*. See WAX.

GLUE, *fish*, is a sort of *glue* made of the nervous and mucilaginous parts of a large fish, found chiefly in the Russian seas.

These parts being boiled, bear a near resemblance to that viscid matter found on the skins of cod-fish. When boiled to the consistence of a jelly, they spread it on a leaf of paper, and form it into cakes; in which state it is sent to us.

Fish-glue is of considerable use in medicine, and divers other arts; where it is better known under the name of *ising-lass* and ICHTHYOCOLLA.

A strong and fine *glue* may be prepared with isinglass and spirit of wine thus: steep the isinglass for twenty-four hours in spirit of wine or common brandy. When the menstruum has opened and mollified the isinglass, they all be gently boiled together, and kept stirring till they appear well mixed, and till a drop thereof, settled to cool, presently turns to a strong jelly. Then strain it, while hot, through a clean linen cloth, into a vessel to be kept close stopped. A gentle heat suffices to dissolve this *glue* into a transparent and almost colourless fluid, but very strong: so that pieces of wood, *glued* together with it, will separate elsewhere than in the parts joined. Boyle's Works, abridg. vol. i. p. 170.

A strong compound *glue* may be made by infusing a mixture of common *glue*, in small pieces, with isinglass *glue*, in as much spirit of wine as will cover them, for about twenty-four hours: then melt the whole together, and add as much powdered chalk as will make it an opake white.

A strong *glue*, that will resist moisture, may be obtained by dissolving gum sandarac and mastic, of each two ounces, in a pint of spirit of wine, and adding about an ounce of clear turpentine: then take equal parts of isinglass and perchance *glue*, and having pounded them into small pieces, put the solution of the gums upon them, and melt the mixture in a covered vessel, with a heat less than that boiling water: then strain the *glue* through a coarse hop cloth, and putting it again over the fire, add about an ounce of powdered glass.

Or, a strong *glue*, that will resist water, may be made by adding half a pound of common isinglass *glue* to two quarts of skimmed milk, and evaporating the mixture to a due consistence.

A *glue*, that will hold against fire and water, may be made by mixing a handful of quick lime with four ounces of linseed oil, boiling them to a good thickness, and spreading the mixture on plates in the shade: it will thus become exceeding hot, but will easily be dissolved over a fire, and be fit for use. See CEMENT.

GLUME, *gluma*, among *Botanists*, a species of cup, consisting of two or three membranous valves, which are often pellucid at the edges. This kind of cup belongs to the grasses. See GRASS.

GLUT, among *Falconers*, the slim substance that lies in a hawk's paunch.

GLUTÆUS, in *Anatomy*, is a name common to three muscles, whose office is to extend the thigh. The first, GLUTÆUS *major*, or the *greater*, arises semi-circularly from the os coccygis, the sinues of the sacrum, the spine of the ilium, and a strong ligament which runs between the sacrum and tubercle of the ischium: and descending, is inserted into the linea aspera, four fingers breadth below the great trochanter. *See Tab. Anat. (Myol.) fig. 1. n. 51. fig. 6. n. 33.*

GLUTÆUS *medius*, or the *middle* one, called *minor*, or *less*, arises from the spine of the ilium, under the former, and is inserted into the superior and external part of the great trochanter. See *Tab. Anat. (Myol.) fig. 1. n. 50. fig. 2. n. 33. fig. 6. n. 32. fig. 7. n. 23.*

GLUTÆUS *maximus*, or *least*, arises from the lower part of the external side of the ilium, under the former, and is inserted at the superior part of the great trochanter. See *Tab. Anat. (Myol.) fig. 7. n. 21.*

GLUTINATIVE, AGGLUTINATIVE, or CONGLUTINATIVE, in *Medicine* and *Pharmacy*. See CONGLUTINATION and AGGLUTINATION.

GLUTTA, a name given by some authors to the *gutta gamba* or GAMBOGE.

GLUTTON *of Russia*, in *Zoology*, is the URSUS *luscus* of Linnæus, and mentioned by authors under the names of wolverene, carcajou, quick-hatch, &c. Mr. Pennant has described this animal as a species of BEAR, with a black sharp-pointed visage; short rounded ears, almost hid in the hair; hairs on the head, back, and belly, reddish, with black tips; sides of a yellowish brown, which passes in the form of a band over the hind-part of the back, above the tail; a white spot on the throat; a white mark, like a crescent, on the breast; strong and short legs of a deep black; five toes on each foot, not deeply divided, though Mr. Edwards only observed four on the fore-feet of the animal which he described: the bottom of the feet covered thickly with hair; claws strong and sharp, and white at their ends; tail clothed with long coarse hairs, those at the base reddish, and at the end black, some of which are six inches long. The length of this animal from the nose to the tail is twenty-eight inches. The whole body is covered with long and thick hair, which varies in colour according to the season. M. Buffon has described this animal (see *Tab. II. Quadrupeds, N° 16.*) as two feet two inches in length, from the tip of the nose to the root of the tail; the face, as far as the eye-brows, is black; the eyes are small and black; from the eye-brows to the ears the hair is black mixed with brown; the ears are short, or about an inch long; the hair under the lower jaw and between the fore-feet is spotted with white; the fore-legs are eleven inches long, and the hind legs twelve inches; the tail is eight inches, and the hair of the tail four inches: the four legs, the tail, and the back, and the lower part of the belly are black; from the shoulders to the root of the tail the hair is reddish; on the sides it is soft, thin, and white: the fore-feet, to the extremity of the claws, are 3¼ inches in length, and 2¼ inches in breadth; they are furnished with five hooked claws, the middle one being 1¼ inch long: the hind feet are 2¼ inches long, and 2¼ broad: the upper jaw has six cutting teeth, one on each side being somewhat thicker than the rest; two large teeth, seven lines long, a little bent, and five grinders, two of which are considerably larger than the others: in the lower jaw there are five grinders, one of which is very large; two large teeth that are a little bent, and six small ones: about the throat and under the eyes there is a little hair, which is about two inches in length.

This animal is found in the northern parts of Europe and Asia, and in Hudson's Bay, and Canada. It has been represented as a very voracious and cruel animal, whence its name *glutton*: it has been said, that it feeds to such a degree, as to be obliged to discharge its load by pressing between two trees; though M. Buffon apprehends that the relations of voyagers have been exaggerated. It is very slow in its motion, and, therefore, takes its prey by surprize. In America it is called the *beaver-eater*, because it devours those animals. It will often lurk on trees, and fall on quadrupeds that pass under it, and fasten to animals of a very large size, and will eat a hole in their bodies, or tear out their eyes. It is particularly eager after the flesh or white fox. In its wild state it is very fierce, but capable of being tamed. It burrows under ground. The skin of the *glutton* is much valued in Siberia and Kamschatka, and the fur is greatly esteemed in Europe: that of the north of Europe and Asia is much finer, and of a more glossy black than that of the American kind. See Pennant's British Zoology, p. 105, &c. Buffon's Hist. Nat. tom. xxvi. p. 70. edit. 1766, and Supplement, tom. vi. p. 67, &c. edit. 1777.

GLYCOPICROSS, in *Botany*, a name by which some authors have called the solanum lignosum, or dulcamara.

GLYCYCALAMUS, a word used singly as the name of a vegetable substance by some of the Greek writers; but by the most ancient it is only used as an epithet for a peculiar kind of lotus. This LOTUS *glycycalamus* is a name given by Mesuë and others to the sativa fistula; but by other of the ancients it seems to have been made the name of the sugar-cane.

GLYCINE, *Cornsilna Kidney-bean tree*, or *Knobbed-rooted Liquorice Pitch*, in *Botany*, a genus of the *diadelphia decandria* class: the characters are, that the empalement of the flower is of one leaf, divided into two lips at the top, the upper lip being obtuse and indented, and the lower lip longer, trifid, and acute: the flower is of the butterfly kind; the ftandard is heart-fhaped, deflexed on the fides, gibbous on the back, and indented at the point: the wings are fmall, oblong, and oval towards their end, and bend backward: the keel is narrow, fickle-fhaped, turning upward with its point to the ftandard, where it is broadeft: it hath ten ftamina, nine of which are joined in one body and the other ftands fingle, terminated by fingle fummits; in the centre is fituated an oblong germen, fupporting a fpiral cylindrical ftyle, crowned by an obtufe ftigma: the germen afterward becomes an oblong pod with two cells, including kidney-fhaped feeds. Miller enumerates five fpecies, and Linnæus two.

GLYCONIAN, GLYCONICS, in the Greek and Latin poetry.

A *Glyconian* verfe is that conſiſting of two feet and a fyllable; at leaſt this is Scaliger's opinion: who adds, that the *Glyconian* verſe was alſo called the *Euripidean* verſe. See VERSE.

Others hold, that the *Glyconian* verſe conſiſted of three feet, a ſpondee, and two dactyls; or rather a ſpondee, choriambus, and an iambus or a pyrrhic: which opinion is the moſt followed.

Sitte diva potens Cypri is a Glyconian verſe.

GLYCYRRHIZA, in *Botany*, and *Medicine*, *liquorice*. See LIQUORICE.

GLYPHE, or GLYPHIS, in *Sculpture* and *Architecture*, a general name for a cavity or canal, whether round, or terminating in an angle; uſed as an ornament in any part.

The Greek word is γλυφὴ, which literally ſignifies *graving, nitching*.

Γλυφὴ is properly a nitch or indenture made in graving; or, more properly, it is the notch in the end of an arrow, in which the ſtring goes.

GLYSTER. See CLYSTER.

GMELINA, in *Botany*, a genus of the *didynamia angiospermia* claſs: the calyx of which is quadridented; the corolla campanulated and divided into four ſegments; two of the antheræ are bipartite, and two ſimple; and the fruit is a drupe inclofed in a bilocular nut or kernel.

GNAPHALIUM. See CUDWEED.

GNAPHEUS, in *Ichthyology*, a name given by Athenæus and other of the Greek writers to the RENCH.

GNAT, *culex*, a genus of the order of *diptera*, or two-winged inſects, whoſe mouth is furniſhed with briſtly ſtings inclofed in a flexile ſheath.

There is no ſpecies of inſect that we have ſo much reaſon to diſlike in regard to the injury it does us as the *gnat*. Others indeed give us more pain with their ſtings, but it is but by accident that we are ſtruck by them; the *gnats* thirſt for our blood, and follow us about in whole companies for it. There are many marſhy places where the legs and arms are all the ſummer ſwelled to an enormous ſize by the repeated bitings of theſe inſects, and in many other countries they are much more troubleſome than with us.

But as troubleſome enemies as theſe little creatures are to us, there is that about them which is extremely worthy our admiration; nor can we indeed fall greatly to admire even the very inſtrument of the miſchief they do. They have beſide this many very obſervable particulars in the courſe of their lives.

All the naturaliſts of late years have applied the microſcope to the examination of the parts of this little animal, and Swammerdam, Hook, Bonanni, Lewenhoeck, &c. have given very good accounts, and very valuable drawings of the creature.

There is a great number of very ſmall ſpecies of *gnats*, and though ſome are conſiderably large, yet none even of theſe approaches to the ſize of the tipula, or father long-legs, as commonly called. The larger tipulæ are therefore eaſily diſtinguiſhed from the *gnats*; but Swammerdam, Geoffroy, Liſter, and others, have very often given us the ſmaller tipulæ among the ſpecies of *gnats*. Both have long ſlender bodies, and both prominent corcelets, which make them look hump-backed; but when either of theſe inſects is taken into the hand it is very eaſily known, the *gnat* having a very long trunk, and the tipula no trunk at all.

There is a prodigious number of ſpecies of the *gnat* kind, taking in the ſmaller ones; Dr. Derham obſerved near forty different ſpecies about Upminſter in Eſſex: but of thoſe of a ſize to be remarked with eaſe, and without the help of glaſſes, there are three principal kinds: the one has its body variegated with white and black; this is the larger kind, and its corcelet is ſtreaked with black or deep brown, and white lines or greyiſh ones; theſe have brown eyes: another is ſmaller than this ſpecies, and has a plain brown body, the colour of the corcelet, and that of the eyes is the ſame as in the larger or firſt ſpecies: the third kind is the ſmaller of the three and the moſt common, has its corcelet reddiſh, or of a faded reddiſh yellow, and the body whitiſh, and on the under part of the belly every ring has one ſingle brown ſpot; the reſt is grey: the eyes of this ſpecies are of a very pleaſant green.

All the *gnats* have a long cylindric body compoſed of eight rings; their corcelet is ſhort, but large, in proportion to the ſize of the fly, and to this are fixed the ſix legs, which are hairy, with ſix joints to each, and at the end two little claws, the wings, and the balancers; four ſtigmata are alſo found here, as is the caſe in other flies: the two firſt of theſe are placed near the head, and have been miſtaken for *ears*.

The antennæ of *gnats* are extremely worth obſervation, and differ much from one another. Some of them are elegantly feathered; theſe belong to the males of certain ſpecies, for the antennæ of the females are not ſo beautiful. The bruſh-horned or male *gnat* has two pair, one of which is ſurrounded, at ſmall diſtances, with long hairs, iſſuing out circularly, each circle leſſening as it approaches the extremity of the antennæ: the other pair are longer and much thicker, and hairy from end to end. In the great bellied or female *gnat*, the firſt pair of antennæ, though of the ſame figure as the male's, has hairs not near ſo long, and the ſecond pair is ſhorter than the firſt by at leaſt three parts in four. Reaumur, Hiſt. Inſ. vol. iv. p. 574. &c. Baker's Microſ. 1743, p. 203, &c. For the trunk and wings of the *gnat*, ſee TRUNK and WINGS.

GNATS, *eggs of*. See EGGS.

For the *eyes of* GNATS, ſee EYES *of Flies*.

GNAT-*worm*, in *Natural Hiſtory*, a ſmall water-inſect, produced of a *gnat*, and which is, after its ſeveral changes, transformed into a *gnat* again.

From the eggs, depoſited by the *gnat* on the ſurface of the water, proceed a number of minute worms, which ſinking to the bottom of the water, form for themſelves coverings of fine ſand or earth, cemented together with a ſort of glue, but open at both ends, that they may come out and enter as occaſion requires.

Theſe worms do not frequent rivers; but ditches, pools, and other ſtanding waters, afford them in vaſt abundance, from the middle of May till toward the beginning of winter. This is the reaſon why watry and moiſt places are found moſt to abound with *gnats*, and why the wet ſummers are found to produce the greateſt numbers of them; becauſe in dry ſeaſons, the ponds and ditches, where they are to paſs their worm-ſtate, are dried up, and the worms killed. Theſe are creepers, however, that one need not go far to ſeek, ſince a veſſel of water, expoſed in any open place in the ſummer months, will not fail to afford plenty of theſe worms in a little time.

Before theſe worms are arrived at their full growth, though they are then but ſmall, they are eaſily found, becauſe they are under a neceſſity of coming frequently to the top of the water, by having occaſion for frequent reſpiration; and to do this, they are obliged to keep the end of a ſmall pipe they are furniſhed with, from the laſt ring of their body, above water. The end of this pipe is hollow and indented, and forms a ſort of funnel on the ſurface of the water: it is of the length of about three rings of the body, and is ſomewhat thicker at its inſertion than at its extremity.

As there is a vaſt number of ſpecies of *gnats*, there is no leſs of the worms from whence they are produced; and to this is in a great meaſure owing the variety in the figures given of the worms by the authors who have treated of them; which may alſo be not a little added to by the particular views in which the draughts have been taken. Notwithſtanding all the variations of theſe figures, the general form of the animal is however the ſame in all, and the ſpecies cannot but be known from any of them. While the worm is young, the body is whitiſh or greeniſh; but when it is at its full growth, and drawn near the time of its changes, it becomes greyiſh. The great tranſparence of the body of this worm gives a fine view of what paſſes within it; it is at any time eaſy to ſee into the motion of the inteſtines, by which the food is puſhed on towards the anus. The two principal tracheæ are alſo ſeen very diſtinctly in this creature: they are two white tubes placed in a parallel direction one to another, and run from the firſt ring to the tube of reſpiration.

The great worm ſeveral times changes its ſkin in the courſe of its life. After three changes of this kind, which uſually happen in the ſpace of three weeks, or thereabout,

thereabout, it undergoes a fourth, where the old skin is as eaſily thrown off as in the reſt, but the animal now appears in a new form, that of a nymph; it is now ſhorter and rounder than before, and the body is ſo bent that the tail is applied to the under part of the head; this, however, is only its form in a voluntary ſtate of reſt, for it can yet move, and when it pleaſes extends its tail, and ſwims about as ſwiftly as when in its other ſtate.

When the creatures have quitted their firſt habitations and the figure of worms, they reaſcend to the top of the water, incloſed in a kind of ſhell, with a large head and mouth, two black eyes, two horns, ſeveral tufts of hairs on different parts of the body, and a tail with a brush of hair at the end of it, which, being ſmeared over with an oily fluid, ſerves to keep them above water; their heads being ſometimes lifted in the air, and ſometimes plunged into the water, while the tail ſides along the ſurface: and when the oil on the tail begins to dry, they ſhed from their mouth a freſh ſupply, which renders it capable of ſteering where they pleaſe, without being wetted and damaged by the water.

All the parts of the future *gnat* may be ſeen in this nymph; the ſkin of it is extremely thin and tranſparent, yet ſufficiently tough and firm for the uſe it is intended for. It is uncertain how long exactly the animal lives in this nymph ſtate; but after the time is accompliſhed, its change into a *gnat* is very quick, and is attended with great danger to the animal, ſince multitudes are drowned in the act of getting out and ſpringing into the air. Beaumur, Hiſt. Inſ. vol. iv. Baker's Microſ. 1743. p. 88.

GNETUM, in *Botany*, a genus of the *monoecia monadelphia* claſs, with male and female flowers on the ſame plant, neither of which have any corolla; the amentum in both is ſcaly; the filament of the male is ſingle, with double antherae; the ſtyle of the female is furniſhed with a triſid ſtigma: the fruit is a monoſpermous drupe.

GNIDIA, in *Botany*, a genus of the *octandria monogynia* claſs; the calyx of which is infundibuliform, and divided into four ſegments; the flower conſiſts of four petals, inſerted into the calyx; the fruit is in the ſhape of a berry, containing a ſingle ſeed.

GNOMES, GNOMI, a name which the Cabbaliſts give to certain inviſible people, whom they ſuppoſe to inhabit the inner parts of the earth, and to fill it to the centre.

They are repreſented as very ſmall of ſtature, tractable, and friendly to men; and are made the guardians of mines, quarries, hidden treaſures, &c. Vigenere calls them *Gnomons*: the females of this ſpecies are called *Gnomides*.

Vigneul de Marville, in his Melange de Hiſtoire & de Literature, tome i. p. 100. gives a relation of a conference with a philoſopher of this claſs, who held, that an infinity of ſpirits inhabited each of the four elements, fire, air, water, and earth, under the denomination of *Salamanders*, *Sylphs*, *Ondins*, and *Gnomes*; that the *Gnomes* are employed in working or actuating the machines of brutes upon earth.

He added, that ſome philoſophers of that ſect held that theſe ſpirits were of two ſexes, for the two ſexes of beaſts or moving machines; that they were more or leſs perfect as the beaſts were; and that there was an infinite number of exceedingly ſmall ones, to actuate the infinite number of inſects and animalcula, both thoſe that are viſible and thoſe which are too ſmall to come under our ſenſes; that all theſe ſpirits, in general, govern their reſpective machines according to the diſpoſition of the parts or organs, the humours, temperaments, &c. that they do not lay hold of all machines indifferently, but of thoſe ſuited to their own character, element, &c. that a haughty one, for inſtance, ſeizes a Spaniſh gennet; a cruel one a tyger, &c.

GNOME, *Γνωμη*, or *ſententia*, is alſo uſed for a ſhort, pithy, and ſententious obſervation, reflection, or the like, which is worthy to be treaſured up and remembered.

Such is that of Juvenal, *Orandum eſt, ut ſit mens ſana in corpore ſano*. The writers of rhetoric diſtinguiſh ſeveral kinds of *gnomes*, according as they turn on words, on actions, or both; denominating them *verbal*, *active*, and *mixed gnomes* or *chriae*. See APOPHTHEGM.

GNOMON, in *Dialling*, is the ſtyle, pin, or cock of a dial, the ſhadow whereof pointeth out the hours.

The word is Greek *γνωμων*, which literally imports ſomewhat that makes a thing known; becauſe the ſtyle or pin indicates or makes the hour, &c. known.

The *gnomon* of every dial is ſuppoſed to repreſent the axis of the world; and therefore the two ends or extremities thereof muſt directly anſwer to the north and ſouth poles. See DIAL and DIALLING.

GNOMON, in *Geometry*. If a parallelogram be divided into four leſſer ones, by two lines interſecting each other, and one of theſe parallelograms be retrenched or taken away, the other three will make a *gnomon*, ordinarily called a *figure*.

Or, a *gnomon*, in a parallelogram, may be ſaid to be a figure formed of the two complements, together with either of the parallelograms about the diameter. Thus, in the parallelogram AC, *Tab.* II. *Geometry*, *fig.* 47. the *gnomon* is M + *x* + *z* + N, or M + N + X + Z.

GNOMON, *in Aſtronomy*, denotes an inſtrument or apparatus for meaſuring the meridian altitudes, and declinations of the ſun and ſtars.

Thoſe converſant in obſervations prefer the *gnomon*, by ſome called the *aſtronomical gnomon*, to the ſmaller quadrants, both as more accurate, eaſier made, and more eaſily applied.

Accordingly, both ancients and moderns have made uſe of *gnomons*, or upright pillars of a known height, erected on a level pavement, for making their more conſiderable obſervations.

The moſt ancient obſervation of this kind, extant, is that made by Pytheas, in the time of Alexander the Great, at Marſeilles, where he found the height of the *gnomon* was to the meridian ſhadow, at the ſummer ſolſtice, as 21734 to 6000; juſt the ſame as Gaſſendus found it to be, by an obſervation made at the ſame place, almoſt two thouſand years after, viz. in the year 1636. Ricciol. Almag. vol. i. lib. iii. cap. 14.

Ulugh Beigh, king of Parthia, &c. uſed a *gnomon* in the year 1437, which was one hundred and eighty Roman feet high: that erected by Ignatius Dante, in the church of St. Petronius, at Bologna, in the year 1576, was fifty-ſeven feet high: M. Caſſini erected another twenty feet high in the ſame church, in the year 1655.

The Egyptian OBELISKS were alſo uſed as *gnomons*; and we may add, that the Spaniards, in their conqueſt of Peru, found pillars of curious and coſtly workmanſhip ſet up in ſeveral places, by the meridian ſhadows of which their antiquaries or philoſophers had, by long experience and repeated obſervations, learned to determine the times of the equinoxes; which ſeaſons of the year were celebrated with great feſtivity and rich offerings, in honour of the ſun. Garcilaſſo de la Vega Hiſt. Peru. lib. ii. cap. 22. See MERIDIAN *line*.

To erect an aſtronomical GNOMON, *and obſerve the meridian altitude of the ſun by the ſame.* Erect a perpendicular ſtyle, of a conſiderable height, on the meridian line; note the point where the ſhadow of the *gnomon* terminates when projected along the meridian line: meaſure the diſtance of that extreme from the *gnomon*, i. e. the length of the ſhadow: thus having the height of the *gnomon*, and the length of the ſhadow, the meridian altitude of the ſun is eaſily found.

Suppoſe, e. gr. TS (*Tab. Optics*, *fig.* 13.) the *gnomon*, and TV the length of the ſhadow. Here, in the right-angled triangle STV, having the two ſides TV and TS, the angle V, which is the quantity of the ſun's altitude, is found out by this analogy: as the length of the ſhadow TV: is to the altitude of the *gnomon* TS:: ſo is the whole line of radius: to the tangent of the ſun's altitude above the horizon.

The following example will ſerve to illuſtrate this propoſition: Pliny tells us, Nat. Hiſt. lib. ii. cap. 72. that at Rome, at the equinoxes, the ſhadow is to the *gnomon* as 8 to 9: ſuppoſe, then, the *gnomon* TS to be 90 feet, and the ſhadow TV 80 feet, and we ſhall have the angle V equal to 48° 22', which is the height of the equator at Rome, and the elevation of the pole there is 41° 38'. Ricciolus takes notice of the following defects in the obſervations of the ſun's height, made with the *gnomon* by the ancients and ſome of the moderns: they did not reckon the ſun's parallax, which makes his apparent altitude leſs, by the quantity of the parallax, than it would be, if the *gnomon* were placed at the centre of the earth: they did not conſider refraction, by which the apparent height of the ſun is a little increaſed; and they made their calculations from the length of the ſhadow, as if it were terminated by a ray coming from the centre of the ſun's diſk, whereas the ſhadow is really terminated by a ray coming from the upper edge of the ſun's diſk; ſo that, inſtead of the height of the centre of the ſun, their calculations gave the height of the upper edge of his diſk: and, therefore, to the altitude of the ſun found by the *gnomon*, the ſun's parallax muſt be added, and from the ſum, the ſun's ſemi-diameter and refraction, which is different in different altitudes, muſt be ſubtracted: conſequently, the height of the equator at Rome, corrected, will be 48° 4' 13", the complement of which, or 41° 55' 47", is the elevation of the pole. Ricciol. Geogr. ref. lib. vii. cap. 4.

The preceding problem may be reſolved more accurately thus: make a circular perforation in a braſs plate, to tranſmit enough of the ſun's rays to exhibit his image on

the

the floor; fix it parallel to the horizon in a high place, proper for obſervation; then let fall a line and plummet, wherewith to meaſure the height of the perforation from the floor. Take care the floor be perfectly level and exactly horizontal, and let it be whitened over, to exhibit the ſun more diſtinctly. Draw a meridian line thereon, paſſing through the foot or centre of the *gnemon*, i. e. through the point the plummet points out: note the extreme points of the ſun's diameter on the meridian line K and I, and from each ſubtract a right line equal to the ſemi-diameter of the aperture; viz. K H (*Tab. Aſtron. fig.* 57.) on one ſide, and L I on the *other*. Then will H I. be the image of the ſun's diameter, which biſected in B, gives the point on which the rays fall from the centre of the ſun.

Now having given the right line A B, and the altitude of the *gnemon*, with the angle A, which is right, the angle A B G, or the apparent altitude of the ſun's centre, is eaſily found: for, aſſuming one of the given ſides A B for radius, A G will be the tangent of the oppoſite angle B. Then ſay, as one leg, A B: is to the other A G: ſo is the whole line: to the tangent of the angle B.

GNOMONIC *column*. See COLUMN.

GNOMONIC *polyhedron*. See POLYHEDRON.

GNOMONIC, or GNOMONICAL *projection*, that which repreſents the circles of a hemiſphere, upon a plane touching it in the vertex, by lines or rays from the centre of the hemiſphere to all the points of the circles to be projected.

In this projection, all the great circles of the ſphere are projected into right lines. Any leſſer circle parallel to the plane of projection is projected into a circle. And any leſſer circle not parallel to the plane of projection, is projected into a conic ſection.

The *gnomonic projection* is alſo called the *horologiographic projection*, becauſe it is the foundation of DIALLING. In other reſpects it is not much uſed, becauſe the circles of the ſphere are projected into conic ſections, which are difficult to deſcribe. However this projection has its conveniences in the ſolution of ſome problems of the ſphere, on account of the great circles being all projected into right lines.

Mr. Emerſon, known by an ingenious treatiſe upon Fluxions, and a variety of other publications, has given the theory and practice of the *gnomonic projection*, in his Treatiſe on the Projection of the Sphere, Lond. 1749, 8vo.

GNOMONICA, *Tranſmon*, of GNOMONICS, the art of DIALLING, or of drawing ſun and moon-dials, &c. on any given plane.

It is thus called, as it ſhews how to find the hour of the day, &c. by the ſhadow of a *gnomon* or ſtyle.

GNOSIMACHII, an ancient ſect in religion, whoſe diſtinguiſhing character was, that they were profeſſed enemies of all ſtudied knowledge in divinity.

The word is γνωσιμαχοι, q. d. an enemy of wiſdom or knowledge.

Damaſcenus ſays, that they were perfectly averſe to all the gnoſes of Chriſtianity, i. e. to all the ſcience or technical knowledge thereof. They held it an uſeleſs labour to ſeek for gnoſes in the holy ſcriptures; and ſaid, that God requires nothing of men but good works; that it were, therefore, much better to walk with more ſimplicity, and not to be ſo ſolicitous about the dogmata of the goſſilic life.

GNOSTICS, ancient heretics, famous from the firſt riſe of Chriſtianity, principally in the Eaſt.

It appears from ſeveral paſſages of the ſacred writings, particularly 1 John ii. 18. 1 Tim. vi. 20. and Col. ii. 8. that many perſons were infected with the *Gnoſtic* hereſy in the firſt century; though the ſect did not render itſelf conſpicuous either for number or reputation, before the time of Adrian, when ſome writers erroneouſly date its riſe.

The word is formed of the Latin *gnoſticus*, and that of the Greek γνωστικος, *knowing*, of γινωσκω, *I know*.

The name *Gnoſtic* was adopted by thoſe of this ſect, as if they were the only perſons who had the true knowlege of Chriſtianity. Accordingly, they looked on all other Chriſtians as ſimple, ignorant, and barbarous perſons, who explained and interpreted the ſacred writings in a too low, literal, and unedifying ſignification.

At firſt, the *Gnoſtics* were only the philoſophers and wits of thoſe times, who formed themſelves a peculiar ſyſtem of theology, agreeable to the philoſophy of Pythagoras and Plato; to which they accommodated all their interpretations of ſcripture. But

GNOSTICS afterwards became a generical name, comprehending divers ſects and parties of heretics, who roſe in the firſt centuries, and who, though they differed among themſelves as to circumſtances, yet all agreed in ſome common principles. They were ſuch as corrupted the doctrine of the goſpel by a profane mixture of the tenets of the oriental philoſophy, concerning the origin of evil and the creation of the world, with its divine truths. Such were the VALENTINIANS, SEMONIANS, CARPOCRATIANS, NICOLAITANS, &c.

GNOSTICS was ſometimes alſo more particularly attributed to the ſucceſſors of the firſt Nicolaitans and Carpocratians, in the ſecond century, upon their having aſſide the names of the firſt authors. Such as would be thoroughly acquainted with all their doctrines, reveries, and viſions, may conſult St. Irenæus, Tertullian, Clemens Alexandrinus, Origen, and St. Epiphanius; particularly the firſt of theſe writers, who relates their ſentiments at large, and confutes them at the ſame time: indeed, he dwells more expreſsly on the Valentinians than any other ſort of *Gnoſtics*; but he ſhews the general principles wherein all their miſtaken opinions were founded, and the method they followed in explaining ſcripture. He accuſes them with introducing into religion certain vain and ridiculous genealogies; i. e. a kind of divine proceſſions or emanations, which had no other foundation but in their own wild imagination.

In effect, the *Gnoſtics* confeſſed, that theſe æons or emanations were no-where expreſsly delivered in the ſacred writings; but inſiſted at the ſame time, that Jeſus Chriſt had intimated them in parables to ſuch as could underſtand him. They built their theology not only on the goſpels and the epiſtles of St. Paul, but alſo on the law of Moſes and the prophets.

Theſe laſt laws were peculiarly ſerviceable to them, on account of the allegories and alluſions with which they abound; which are capable of different interpretations. However, their doctrine concerning the creation of the world by one or more inferior beings of an evil or imperfect nature, led them to deny the divine authority of the books of the Old Teſtament, which contradicted this idle fiction, and filled them with an abhorrence of Moſes and the religion he taught; alledging, that he was actuated by the malignant author of this world, who conſulted his own glory and authority, and not the real advantage of men. Their perſuaſion that evil reſided in matter, as its centre and ſource, made them treat the body with contempt, diſcourage marriage, and reject the doctrine of the reſurrection of the body and its re-union with the immortal ſpirit. Their notion, that malevolent genii preſided in nature, and occaſioned diſeaſes and calamities, wars, and deſolations, induced them to apply themſelves to the ſtudy of magic, in order to weaken the powers or ſuſpend the influence of theſe malignant agents.

The *Gnoſtics* conſidered Jeſus Chriſt as the Son of God, and, conſequently, inferior to the Father, who came into the world for the reſcue and happineſs of miſerable mortals, oppreſſed by matter and evil beings: but they rejected our Lord's humanity, on the principle that every thing corporeal is eſſentially and intrinſically evil; and, therefore, the greateſt part of them denied the reality of his ſufferings. They let a great value on the beginning of the goſpel of St. John, where they fancied they ſaw a great deal of their æons or emanations under the *Word*, the *Life*, the *Light*, &c. They divided all nature into three kinds of beings, viz. *hylic*, or material; *pſychic*, or animal; and *pneumatic*, or ſpiritual.

On the like principle they alſo diſtinguiſhed three ſorts of men; *material*, *animal*, and *ſpiritual*. The firſt, who were material, and incapable of knowledge, inevitably periſhed, both ſoul and body; the third, ſuch as the *Gnoſtics* themſelves pretended to be, were all certainly ſaved; the pſychic, or animal, who were the middle between the other two, were capable either of being ſaved or damned, according to their good or evil actions.

With regard to their moral doctrines and conduct, they were much divided. The greateſt part of this ſect adopted very auſtere rules of life, recommended rigorous abſtinence, and preſcribed ſevere bodily mortifications, with a view of purifying and exalting the mind. However, ſome maintained, that there was no moral difference in human actions; and thus, confounding right with wrong, they gave a looſe rein to all the paſſions, and aſſerted the innocence of following blindly all their motions, and of living by their tumultuous dictates. They ſupported their opinions and practice by various authorities: ſome referred to fictitious and apocryphal writings of Adam, Abraham, Zoroaſter, Chriſt and his apoſtles; others boaſted that they had deduced their ſentiments from ſecret doctrines of Chriſt, concealed from the vulgar; others affirmed, that they arrived at ſuperior degrees of wiſdom by an innate vigour of mind; and others aſſerted that they were inſtructed in theſe myſterious parts of theological ſcience by Theudas, a diſciple of St. Paul, and by Matthias, one of the friends of our Lord. The tenets of the ancient *Gnoſtics* were revived in Spain, in the fourth century, by a ſect called the PRISCILLIANISTS. See Moſheim's Eccl. Hiſt. vol. i. p. 107, &c. edit. octavo, 1758.

The appellation *Gnoftic* fometimes alſo occurs in a good ſenſe, in the ancient eccleſiaſtical writers, and particularly Clemens Alexandrinus, who, in the perſon of his *Gnoſtic*, deſcribes the characters and qualities of a perfect Chriſtian. This point he labours in the ſeventh book of his Stromata, where he ſhews, that none but the *Gnoſtic*, or learned perſon, has any true religion. He affirms, that were it poſſible for a knowledge of God to be ſeparated from eternal ſalvation, the *Gnoſtic* would make no ſcruple to chooſe the knowledge; and that if God would promiſe him impunity in doing of any thing he has once ſpoken againſt, or offer him heaven on thoſe terms, he would never alter a whit of his meaſures.

In this ſenſe the father uſes *Gnoſtics*, in oppoſition to the heretics of the ſame name; affirming that the true *Gnoſtic* is grown old in the ſtudy of the holy Scripture; and that he preſerves the orthodox doctrine of the apoſtles, and of the church; whereas the falſe *Gnoſtic* abandons all the apoſtolical traditions, as imagining himſelf wiſer than the apoſtles.

At length the name *Gnoſtic*, which originally was the moſt glorious, became infamous, by the idle opinions and diſſolute lives of the perſons who bore it; much as, in the preſent age, it has fared with the name *quietiſt*, *petiſt*, &c.

GO, in *Ichthyography*, a name given by ſome to the common rock-fiſh, or ſea-gudgeon. See GOBET.

Go is ſometimes uſed, in *Law*, in a ſpecial ſignification. Thus, to *go without day*, and to *go to God*, denote as much as to be diſmiſſed the court, and to be acquitted.

GOACONEZ. in *Botany*, the name of an American tree, which affords a white balſam, but little known in Europe; it is called by ſome authors *balſamum album*, and by others *balſamum peruvianum*.

GOAD, *Stimulus*, a ſtick armed at one end with a pointed iron, to prick and urge on oxen, and other cattle.

GOAL. See GAOL.

GOAN, the name of a Perſian tree, of the aſhes of which they make a ſort of antiſpodion, or medicinal powder, for diſeaſes of the eyes.

GOARING, on ſhip-board. The ſeamen ſay a ſail is cut *gearing*, when it is cut ſloping by degrees, and is broader at the clew than at the cat-ling, as all top-ſails and top gallant-ſails are.

GOAT, *Capra*, in the Linnæan ſyſtem of *Zoology*, makes a diſtinct genus of animals of the order of the *pecora*, the diſtinguiſhing characters of which are, that its horns are hollow, turned upward, and not ſmooth, but annulated on their ſurface; that it has eight cutting teeth in the lower jaw, and none in the upper, and that the male is generally bearded. This genus comprehends all the goat kind, the *gazella*, *ibex*, *rupicapra*, &c. the characters of which, according to Mr. Ray, are theſe; that it is covered with hairs, not with wool; that its horns are leſs crooked than thoſe of the ſheep, and that it has a beard hanging down from its chin, and is of a ſtrong ſmell.

It is very ſingular that this genus of animals are all able to run and climb about the rugged parts of mountains without falling, though their feet ſeem by no means contrived by nature for any ſuch purpoſes. Linnæus enumerates twelve known ſpecies of this animal. 1. The *capra hircus*, or common kind, ſufficiently known. Linnæus reckons the Angora *goat* of Aſiatic Turkey a variety of this; the hair of this animal is of a ſilky fineneſs and ſilvery whiteneſs, in curled locks of eight or nine inches in length, and forms the baſis of our fine CAMBLETS. The hair is imported in form of thread; for the Turks will not ſuffer it to be exported raw, becauſe the ſpinning employs multitudes of poor. This variety is confined to a diſtrict of two or three days journey in extent; for if they change climate, the hair grows coarſer. 2. The *capra mambrina*, or Syrian *goat*. This is remarkable for the length of its ears, which reach almoſt to the ground, and are very like thoſe of the common hunting hound: the horns are black and ſhort, and are very little inflected backwards: it is of the ſhape of the common *goat*, but larger; its colour that of the fox, and is a creature eaſily tamed, and feeds on hay and other vegetables. This ſpecies is very common in the Eaſt, and ſupplies the inhabitants of Aleppo with milk. 3. The *capra depreſſa Africana*, or African *goat*, deſcribed in the German Ephemerides; it is of a duſky grey colour, and has a bundle of erect hairs growing on the middle of its head; and on each ſide, between the eyes and noſe, it has two cavities, which contain a thick, fat, yellowiſh liquor, which afterwards congeals into a black ſubſtance, of a mixed ſmell between thoſe of muſk and caſtor. As ſoon as the matter contained in theſe cavities is taken away, there returns more in its place, which is in like manner dried and hardened by the air. Theſe cavities have no communication with the eyes, and therefore the matter deſcribed here is nothing of the nature of the *lacryma cervi*, mentioned in the catalogues of the materia medica. This creature is figured without horns, becauſe they are very ſmall, and ſcarce perforate the ſkin. The male of this ſpecies is covered with rough hair; and beneath the chin hang two long hairy wattles; the hair of the female is ſmooth, its horns leſs, and it has no wattles. 4. The *capra reverſa*, which is alſo African; with ſhort ſmooth horns, turning a little forwards. Linnæus ſays, that theſe two laſt ſpecies came from America; but Mr. Pennant obſerves, that the *goat*, and every other domeſtic animal was unknown in that country, before its diſcovery by the Spaniards. 5. The IBEX, or wild *goat*. 6. The *rupicapra*. See CHAMOIS and ÆGAGROPILA. 7. The *capra gazella*, or Indian antelope. 8. The *capra cervicapra*, or African antelope, with upright horns, twiſted ſpirally, and ſurrounded almoſt to the top with prominent rings: the ſize of this animal is rather leſs than that of the fallow deer, or buck; its colour, brown mixed with red, and duſky; the belly and inſide of the thighs white; the tail ſhort, black above, and white below: the female wants horns. 9. The *capra hircortica*, with very long ſlender, upright horns, bending at the upper part inward towards each other; ſome are much annulated, and others ſmoother. This animal is of the ſize of the common *goat*, and its colour is red mixed with aſh-colour. It inhabits the inhoſpitable mountains of Laar, in Perſia, and produces the BEZOAR. 10. The *capra dorcas*, or African *gazella* of Ray, with round horns, inclining firſt backwards, bending in the middle, reverting forwards at their ends, and annulated. See GAZELLA and ANTELOPE. 11. The *capra Tartarica*, Scythian antelope, *ibex imberbis*, or *ſaiga* of Buffon, is a ſpecies of *goat* with horns, about a foot long, bending in the middle, the points inclining inwards, the ends ſmooth; the other part ſurrounded with prominent annuli, of a pale yellow colour, and for the moſt part ſemipellucid. The head of this animal is like that of a ſheep; its noſe large and arched, marked through its whole length with a ſmall line, cauſed by the elevation of the *ſeptum narium*; the noſtrils large: the upper lip hangs over the under, and the cutting teeth are ſo looſe in their ſockets as to move with the leaſt touch. The male is covered with rough hair, and has a ſtrong ſmell; the female is ſmoother, timid, and without horns; when attacked by wolves or dogs, the males place them in a circle, ſtand round them, and defend them. The ſkin is ſoft, and excellent for gloves, belts, &c. They are found in flocks of many thouſands between the Tanais and Boryſthenes. See Phil. Tranſ. 1767, p. 344.

12. The *capra ammon*, the *muſimon* of Pliny, the *tragelaphus* of Belon, or Siberian *goat*, with large horns, bending backwards, cloſe at their baſe, diſtant at their points, with circular *rugæ*, or folds. This animal is of the height and ſize of the ram, covered with pale, ferruginous, long hair; the hind legs, belly, and rump, are white; the tail is ſhort and black. The horns of the male are much larger than thoſe of the females. Theſe animals inhabit the north-eaſt parts of Aſia, Barbary, Sardinia, Corſica, and Greece; they live in the mountains, and run ſwiftly among the rocks. They are ſuppoſed by M. Buffon to be the ſheep in a wild ſtate.

Goats may be of great advantage to farmers in ſome parts of the kingdom, as they will live in rocky barren countries, where nothing elſe can get a ſupport for life. They will climb the ſteepeſt rocks, and there browſe upon briars, heath, and ſhrubs, of various kinds, which other creatures will not taſte of. They will feed on graſs in paſtures; but as they love browſing on trees much better, great care muſt be taken to keep them from valuable plantations.

The rutting ſeaſon of theſe animals is from the beginning of September to November; they go with young four months and a half, and bring forth from the latter end of February to the latter end of April. They are much affected by the weather; a rainy ſeaſon makes them thin; and a dry ſunny ſeaſon makes them fat and blythe; they are very libidinous animals, and ſeldom live in our climate above eleven or twelve years.

The beſt kind of *goats* for keeping to advantage ſhould be choſen in this manner: the male ſhould have a large body, his hair ſhould be long, and his legs ſtraight and ſtiff; the neck ſhould be plain and ſhort, the head ſmall and ſlender, the horns large, the eyes prominent, and the beard long. The female ſhould have a large udder, with large teats, and no horns, or very ſmall ones. They ſhould be kept in flocks, that they may not ſtraggle, and they ſhould have good ſhelter both in ſummer and in winter, the heat and cold being both prejudicial to them. They ſhould have no litter in winter, but only a paved floor kept clean. The kids are to be brought up for the table in the ſame manner as our lambs are. They are recommended to lie among horſes, as their ſmell, as is ſup-

supposed, prevents many distempers in those animals. The greatest advantage of these creatures is their milk, which they yield in large quantities. It is sweet, nourishing, and medicinal; an excellent succedaneum for asses milk; and has been, with a tea-spoon full of hartshorn, drank warm in bed in the morning, and at four in the afternoon, and thus repeated for some time, a cure for phthisical people, before their disorder has become inveterate. In some parts of Scotland, Ireland, and Wales, the milk is made into whey, which has been of great service in this and other cases, where coolers and restoratives are necessary. The blood of the he-goat, dried, has been recommended for the pleurisy and inflammatory disorders, and is taken notice of by Dr. Mead in this intention.

They mix *goat's* milk and cow's milk together in many parts of the kingdom, and a very valuable kind of cheese is made of it. Besides this, the kids or young *goats* are very fine food, and the best kinds bring forth these two or three at a time, and that twice a year.

The haunches of the *goat* are frequently salted and dried in some parts of Wales, where it is called *hung venison*. The flesh of a splayed *goat*, six or seven years old, is reckoned the best, and is generally very *forest* and *fat*. It is called *rock-venison*, and is little inferior to that of the deer. The feet of *goats*, killed about four or five years old, is in great esteem, and makes excellent candles.

Goat hair also is of value; it may be sheared as the wool from sheep, and is excellent for making ropes that are to be used in the water, as they will last a great while longer than these made in the common way. A sort of stuff is also made of it in some places.

The whitest wigs are made of the hair of the male *goat*; the whitest and clearest is selected from that which grows on the haunches, where it is longest and thickest. That of the Welch *goats* is preferable to all others, both in length and fineness. The horns are also used for the handles of knives and pen-knives: and the skin is applied to various uses by glovers, &c. Mortimer's Husb. p. 240, &c. Pennant's British Zool. vol. i. p. 36, &c.

GOAT *of Greenland, capra Groenlandica*, in *Zoology*, the name of an animal of the northern parts of the world. We are not perfectly acquainted with the shape or figure of the creature; but its horns are preserved in the museums of the Royal Society, and in some other collections, and are usually an ell long, very much branched, and the branches not flat but rounded, covered all over with a velvety down, composed of short filaments standing erect every way, and about a quarter of a finger's breadth long.

GOAT-*fish, Capriscus*, in *Ichthyography*, the name of a fish, called also by some *caper*. In the middle of its back it has three very strong and large prickles, the first of which is three times as large as any of the others, and all are connected by a membrane. See *Tab. of fish*, N° 5.

The whole fish is covered with a scaly skin; but the scales have more the appearance of those of a serpent, than those of the fish; for they are placed in cancellated lines intersecting one another, and are so well fixed, that they with difficulty come off; and wood or ivory may be polished with the skin, as with the common fish-skin used by the turners, &c. It is of a bluish-green colour, sprouted with a fine blue, and the back and belly-fins are black, with some blue and red spots. Its whole figure is very broad and flat, as well as short, so that it approaches to a round form. It seldom exceeds two pounds in weight. It is caught in the Mediterranean, but not commonly. The skin of it is frequently found in the cabinets of the curious.

GOAT-*sucker*, in *Zoology*, a name by which the *caprimulgus* is called in some parts of England; but its more usual name with us is the *churn-owl*.

GOAT'S-*beard, Tragopogon*, in *Botany*, a genus of the *syngenesia polygamia aequalis* class. Its characters are these: the common empalement of the flower is single, composed of eight acute-pointed leaves, which are alternately large, joined at their base: the flower is composed of many hermaphrodite florets, which are uniform, of one petal, stretched out like a tongue, indented at the points in five parts, and lying over each other like the scales of fish; these have each five short hair-like stamina, terminated by cylindrical summits, and an oblong germen situated under the floret, supporting a slender style the length of the stamina, crowned by two revolving stigmas: the empalement of the flower afterwards swells to a belly, including many oblong, angular, rough seeds, slender at both ends, crowned by a feathery down. Miller enumerates six, and Linnæus eleven species.

There are two or three species of this plant well known among us, the one wild in our meadows and pastures, by the name of *go to bed at noon*, from its flowers always shutting up in the middle of the day; another kept in our gardens for its beautiful red flowers; and a third cultivated for its eculent root, and known by the name of salsafy. This was originally from Italy, and is still kept in many gardens as a good root; but it is not common in our markets.

These plants are propagated by sowing their seeds in spring on an open spot of ground. The salsafy should be sowed in rows at nine or ten inches distance; and when the plants are come up, they should be left at about six inches asunder in the rows; they then require no farther care but to be kept clear from weeds; and if the soil be light, and not too dry, they will grow to a considerable size by winter. The roots are to be taken up for use when the leaves are decayed, and continue in season till March; and then the young shoots, which are very large and thick, are by many boiled as asparagus, and make a very delicate dish. Miller.

GOAT'S *eye*. See EYE.

GOAT'S-*rue, Galega*, in *Botany*, a genus of the *diadelphia decandria* class. Its characters are these: the flower is of the butterfly kind: the standard oval, large, and reflexed; the wings are near the length of the standard; the keel erect, oblong, and compressed; and hath ten stamina which join above their middle: in the center is situated a narrow, cylindrical germen, which afterward becomes a long pointed pod, inclosing several oblong kidney-shaped seeds. Miller reckons three species, natives of warm climates, and Linnæus ten.

In medicine, the common sort, with blue flowers, is esteemed a great alexipharmic and sudorific. It is much used in Italy; but amongst us only as an ingredient in some compositions.

Mr. Boyle celebrates the virtues of *goat's rue* in pestilential and malignant diseases, from his own observation and experience.

GOAT'S *stone, greater*. See SATYRIUM.

GOAT'S *stone, lesser*. See ORCHIS.

GOAT'S *thorn, Tragacantha*, in *Botany*. Its characters are these: the empalement of the flower is indented in five parts, the lower segments being the shortest: the flower is of the butterfly kind, the standard long, erect, and indented at the point; the borders reflexed; the wings shorter than the standard; the keel is of the same length with the wings, and is indented: it has ten stamina, nine of them joined, and one separated, terminated by roundish summits; and a sharp taper germen, supporting an awl-shaped style, crowned by an obtuse stigma. The germen afterward becomes a short swelling pod, having two longitudinal cells, including kidney-shaped seeds. There are four species. Linnæus has joined this genus to that of ASTRAGALUS.

From one species of this genus, M. Tournefort says the gum adragant, or dragon, is produced in Crete. See TRAGACANTH.

GOBELINS, a celebrated manufactory, established at Paris, in the Fauxbourg St. Marcel, for the making of TAPESTRY, and other furniture for the use of the crown. The house where this manufactory is carried on, was built by two brothers, Giles and John *Gobelins*, both excellent dyers; and the first that brought to *Paris*, in the reign of Francis I. the secret of dying that beautiful scarlet colour still known by their name; as well as the little river Bievre, on whose banks they fixed their dye-house; and which is now known by no other name than that of the river of the *Gobelins*.

It was in the year 1667 that this place, till then called *Gobelins Folly*, changed its name into that of *Hotel Royal des Gobelins*, in consequence of an edict of Louis XIV.

Mont. Colbert having re-established, and with new magnificence enriched and completed the king's palaces, particularly the Louvre and Tuilleries, began to think of making furniture suitable to the grandeur of those buildings: with this view he called together all the ablest workmen in the divers arts and manufactures throughout the kingdom; particularly painters, tapestry-makers, sculptors, goldsmiths, chemists, &c. and by splendid offers, pensions, privileges, &c. called others from foreign nations.

And to render the intended establishment firm and lasting, he brought the king to purchase the *Gobelins*, for them to work in, and draw up a system of laws, or policy, in seventeen articles.

By these it is provided, that the new manufactory shall be under the administration of the superintendant of the king's buildings, arts, &c. that the ordinary matters thereof shall take cognizance of all actions and processes brought against any of the persons in the said manufactory, their servants and dependants; that no other tapestry work shall be imported from any other country, &c.

The *Gobelins* has ever since remained the first manufactory of this kind in the world. The quantity of the finest

and nobleſt works that have been produced by it, and the *number* of the beſt workmen bred up therein, are incredible; and the preſent flouriſhing condition of the arts and manufactures of France is, in a great meaſure, owing thereto.

Tapeſtry work, in particular, is their glory. During the ſuperintendance of M. Colbert, and his ſucceſſor, M. de Louvois, the making of tapeſtry is ſaid to have been practiſed to a degree of perfection, ſcarce inferior to what was before done by the Engliſh and French.

The battles of Alexander, the four ſeaſons, four elements, the king's palaces, and a ſeries of the principal actions of the life of Louis XIV. from the time of his marriage to the firſt conqueſt of Franche Comté, done from the deſigns of M. le Brun, director of the manufactory of the *Gobelins*, are maſter-pieces in their kind.

GOBEMOUCH, the *fly-catcher lizard*, a ſpecies of American lizard that is always employed in catching of flies. It is the ſmalleſt of all the lizard kind, and is very beautiful, its ſkin often appearing as if covered with leaf-gold, or leaf-ſilver, and in ſome others of a green, or red and gold, wonderfully bright and beautiful. They are not at all ſhy or fearful of men; but as they do not hurt, ſo they ſeem to dread none; they enter chambers and cloſets, and do no ſort of damage, but deſtroy the flies and other troubleſome vermin they find there. Their whole lives ſeem ſpent in the chace of theſe inſects, and it is a very pleaſing thing to obſerve the various ways they have of catching them. They are very cleanly creatures, and may be ſuffered to run over the table at meal time; where if they ſee a fly, they will purſue it over the very hands or cloaths of people, or over the diſhes, without doing the leaſt hurt.

Notwithſtanding their great beauty while alive, they are only of a duſky grey when dead, all their other colours immediately vaniſhing.

GOBIO *capitatus*, a name by which many writers in *Zoology* have called the *cottus*, being the *cottus Lævis*, with two ſpines on his head, of Linnæus. This is a ſmall fiſh, called in Engliſh the BULL-*head*, or *miller's thumb*.

GOBIONARIA, in *Ichthyology*, a name given by Gaza and others to the little fiſh called *cobitis*, and APHUA *cobitis* by the ancient Greeks, and by many of the modern authors; and by ſome *marſio*, or ſimply *cobitis*.

GOBIUS, in *Ichthyology*, the name of a genus of fiſhes of the acanthopterygious, or prickly-finned kind; the characters of which are theſe: the branchioſtege membrane contains on each ſide very diſtinct bones; theſe are very irregular in their ſize, the firſt and fourth being much broader than the others: the belly-fins grow together ſo as to form one ſingle fin, of the ſhape of a funnel; theſe, and the pectoral fins, are placed at the ſame diſtance from the head: there are two fins on the back, the anterior of which conſiſts of ſomewhat rigid bones: the ſcales are rough, the body is oblong, the head compreſſed, and the eyes covered with the common ſkin of the head. It is eaſy to ſee from theſe characters, that the common river gudgeon is no *gobius*, as thus diſtinguiſhed. The ſpecies properly belonging to this genus are four. Artedi.

According to Willughby, there are only three kinds of this fiſh.

In the Linnæan ſyſtem, the *gobius* is a genus of the *thoracic* order, with eyes placed near each other, and two ſmall holes between them, four branchioſtegous rays, and ventral fins united. Of this genus Linnæus enumerates eight ſpecies; viz. *gobius niger*, *paganellus*, *cluvitis*, with the anal fin compoſed of nine rays, of *gobius albeſcens* of Gronovius, found in China; *aphya*, *jozo*, *pellucidus*, with horizontal teeth in the lower mandible, found alſo in China; *barbarus*, with pectoral fins, forming a kind of fan, with the firſt dorſal fin containing twelve, and the laſt thirteen rays; and *anguillaris*, with a ſingle dorſal fin. See GOBET, PAGANELLUS, APHUA, and JOZO.

GOBIUS *aſper*, in *Ichthyology*, a name given by Geſner and others to a ſpecies of PERCH called by many *aſper piſcatilis*, a name confounding it with many other *different* fiſhes, and by Linnæus *perca aſper*. It is diſtinguiſhed among the ſpearch tribe by Artedi under the name of the ſpearch with eight or nine black lines on each ſide.

GOBIUS *fluviatilis*, in *Ichthyology*. See GUDGEON.

GOBIUS *marinus*. See GOBET.

GOBLET, or GOBLET, a kind of drinking cup, or bowl, ordinarily of a round figure, and without either foot or handle.

The word is French, *gobelet*; which Salmaſius, and others, derive from the barbarous Latin *cupa*. Budæus deduces it from the Greek κυβελλον, a *ſort of cup*.

GOBLETS, made of the wood tamariſk, are ranked among medicinal drugs; becauſe the liquors infuſed a while therein, are ſuppoſed to acquire a quality which renders them good in diſeaſes of the ſpleen.

GOBONE', or GOBONY, in *Heraldry*, the ſame as COMPONE'.

GOD, an immaterial, intelligent, and free being; of perfect goodneſs, wiſdom, and power; who made the univerſe, and continues to ſupport it, as well as to govern and direct it by his providence.

The Rabbins and Hebraiſts, particularly St. Jerom, and the interpreters, reckon up ten different names of *God* in Scripture; which are אל, *El*, אלהים, *Elohim*, אלוהי, *Elohi*, or in the ſingular, אלוה *Eloah*, צבאות, *Tſbaoth*, עליון, *Elion*, אדוני, *Adonai*, יה, *Jah*, שדי, *Shaddai*, יהוה, *Jehovah*: but it is wrong to divide אלוהי from צבאות; they ſhould be but one name אלוהיצבאות, *Elohatſboah*, i. e. *God of hoſts*. Of theſe names there are three which expreſs the eſſence of *God*, and are proper names; viz. אדוני, *Eloah*, יה, *Jah*, and יהוה, *Jehovah*: the others are only names of attributes. St. Jerom gives a particular explanation of theſe ten names, in his epiſtle to Marcella; and Buxtorf the younger has an expreſs diſſertation on the ſame, Diſſertatio de Nominibus Dei. The Jeſuit Souciet has three ſeveral diſcourſes on the three names, *El*, *Elohim*, and *Jehovah*, printed at Paris, 1715. The Hebrews call the name of *God* בוראיע אותיות, and the Greeks, after this example, τετραγραμματον; as conſiſting of four letters, which it is obſerved to do in moſt languages: thus, in the Hebrew *God* is called יהוה, *Jehovah*; in the Greek, Θεος; in Latin, *Deus*; in Spaniſh, *Dios*; in Italian, *Idio*; in French, *Dieu*; in the ancient Gauliſh, *Dies*; in ancient German, *Diet*; in the Slavonic, *Buch*; in Arabic, *Alla*; in the Poliſh, *Beng*; in the Pannonian, *Iſten*; in the Egyptian, *Tore*; in the Perſian, *Sare*; in the language of the Magi, *Oſe*. But a diſtinction ought here to be made between the name *God*, and the name of *God*; it being the latter, not the former, that in the Hebrew conſiſts of four letters. The name or word *God*, in the Hebrew, is אלה, *Eloah*, which conſiſts but of three letters; or in the plural אלהים, *Elohim*, which conſiſts of five. The name of God is יהוה, *Jehovah*; which is the τετραγραμματον, or the name of four letters among the Hebrews and Greeks. But it is not this name that anſwers to the Greek Θεος, Latin *Deus*, Engliſh *God*, &c. In reality, none of theſe languages have any proper name of *God*, as יהוה, *Jehovah*, is in the Hebrew.

By his immateriality, intelligence, and freedom, *God* is diſtinguiſhed from *fate*, *nature*, *neceſſity*, *chance*, *anima mundi*, and from all the other fictitious beings, acknowledged by the Stoics, Pantheiſts, Spinoſiſts, and other ſorts of atheiſts.

The knowledge of *God*, his nature, attributes, word and works, with the relations between him and his creatures, make the ſubject of the extenſive ſcience called *theology*.

In Scripture *God* is deſined by, I am that I am; Alpha and Omega; the Beginning and End of all things.

Among philoſophers, he is defined a being of infinite perfection; or in whom there is no defect of any thing which we conceive may raiſe, improve, or exalt his nature.

Among men, he is chiefly conſidered as the firſt cauſe, the firſt being, who has exiſted from the beginning, has created the world, or who ſubſiſts neceſſarily, of of himſelf.

Sir Iſaac Newton chooſes to conſider and define *God*, not as is uſually done, from his perfection, his nature, exiſtence, or the like; but from his dominion. "The "word *God*, according to him, is a relative term, and "has a regard to ſervants: it is true, it denotes a being "eternal, infinite, and abſolutely perfect; but a being, "however eternal, infinite, and abſolutely perfect, with-"out dominion, would not be *God*.

"The word *God*, the ſame author obſerves, frequently "ſignifies *Lord*; but every lord is not *God*: it is the do-"minion of a ſpiritual being or lord, that conſtitutes "*God*; true dominion, true *God*; ſupreme, the ſupreme; "feigned, the falſe god.

"From ſuch true dominion it follows, that the true *God* "is living, intelligent, and powerful; and from his "other perfections, that he is ſupreme, or ſupremely "perfect: he is eternal, and infinite: omnipotent, and "omniſcient; that is he endures from eternity to eter-"nity, and is preſent from infinity to infinity.

"He governs all things that exiſt, and knows all things "that are to be known: he is not eternity, or infinity, "but eternal and infinite: he is not duration or ſpace, "but he endures, and is preſent: he endures always, and "is preſent every where; and by exiſting always and "every where, he conſtitutes the very thing, duration "and ſpace, eternity and infinity.

"Since every particle of ſpace is always, and every in-"diviſible moment of duration every where, the Cre-"ator and Lord of all things can never be *nowhere*, or "*noſquam*.

"He

" He is omnipresent, not only virtually, but also substantially; for power without substance cannot subsist. " All things are contained, and move, in him; but without any mutual passion: he suffers nothing from the " motions of bodies; nor do they undergo any resistance " from his omnipresence.

" It is confessed, that *God* exists necessarily; and by the " same necessity he exists always, and every where. " Hence, also, he must be perfectly similar; all eye, all " ear, all brain, all arm, all the power of perceiving, " understanding, and acting; but after a manner not at " all corporeal, after a manner not like that of men, after a manner wholly to us unknown.

" He is destitute of all body, and all bodily shape; and " therefore cannot be seen, heard, nor touched; nor " ought to be worshipped under the representation of " any thing corporeal.

" We have ideas of the attributes of *God*, but do not " know the substance even of any thing: we see only " the figures and colours of bodies, hear only sounds, " touch only the outward surfaces, smell only odours, " and taste tastes; and do not, cannot, by any sense, or " any reflex act, know their inward substances; and " much less can we have any notion of the substance of " *God*.

" We know him by his properties, and attributes; by " the most wise and excellent structure of things, and " by final causes; but we adore and worship him only on " account of his dominion: for *God*, setting aside dominion, providence, and final causes, is nothing else but " fate and nature." Newt. Philos. Nat. Princip. Mathem. calce.

An ingenious divine has wrought these thoughts of that admirable philosopher into form, and ripened them into a more express system, in a discourse on this subject. Maxwell's Disc. concerning *God*.

We shall here subjoin a compendious abstract of the principal arguments that have been alledged in proof of the existence of *God*. The admirable metaphysician and divine, Dr. Clarke, has demonstrated this truth, with that clearness and force of reasoning, for which he is so eminently distinguished, by a series of propositions, mutually connected and dependent, and forming a complete and unanswerable argument in proof both of the being and attributes of the Deity. 1. Something has existed from all eternity; for, since something now is, something always was: otherwise the things that now are must have been produced out of nothing, absolutely and without cause; which is plain contradiction in terms. 2. There has existed from eternity some one unchangeable and independent being: or else, there has been an infinite succession of changeable and dependent beings produced one from another in an endless progression, without any original cause at all. Which supposed, this series of beings can have no cause of its existence, because it includes all things that are or ever were in the universe: nor is any one being in this infinite succession self-existent or necessary, and therefore it can have no reason of its existence within itself; and it was equally possible, that from eternity there should never have existed any thing at all, as that a succession of such beings should have existed from eternity. Consequently, their existence is determined by nothing; neither by any necessity of their own nature, because none of them are self-existent; nor by any other being, because no other is supposed to exist. 3. That unchangeable and independent being, which has existed from eternity, without any external cause of its existence, must be self-existent, i. e. it must exist by an absolute necessity originally in the nature of the thing itself, and antecedent in the natural order of our ideas to our supposition of its being. For whatever exists must either have come into being out of nothing without cause; or it must have been produced by some external cause; or it must be self-existent: but the two former suppositions are contrary to the two first propositions. From this last proposition it follows, that the only true idea of a self-existent, or necessarily existing being, is the idea of a being, the supposition of whose non-existence is an express contradiction; and this idea is that of a most simple being, absolutely eternal and infinite, original and independent. It follows also, that nothing is so certain as the existence of a supreme independent cause; and likewise, that the material world cannot possibly be the first and original being, uncreated, independent, and of itself eternal; because it does not exist by an absolute necessity in its own nature, for so that it must be an express contradiction to suppose it not to exist. With respect both to its form and matter, the material world may be conceived not to be, or to be in any respect different from what it is, without a contradiction. 4 and 5. The substance or essence of the self-existent being is absolutely incomprehensible by us; nevertheless, many of the essential attributes of this nature are strictly demonstrable, as well as his existence. The self-existent being, having no cause of its existence but the absolute necessity of its own nature, must of necessity have existed from everlasting, without beginning; and must of necessity exist to everlasting, without end. 6. The self-existent being must of necessity be infinite and omnipresent. Such a being must be every where, as well as always, unalterably the same. It follows from hence, that the self-existent being must be a most simple, unchangeable, incorruptible being; without parts, figure, motion, divisibility, and other properties of matter, which are utterly inconsistent with complete infinity. 7. The self-existent being must of necessity be but one; because in absolute necessity there can be no difference or diversity of existence; and, therefore, it is absolutely impossible, that there should be two independent self-existent principles, such, e. g. as *God* and matter. 8. The self existent and original cause of all things must be an intelligent being. This proposition cannot be demonstrated strictly and properly *a priori*; but *a posteriori*, the world affords undeniable arguments to prove, that all things are the effects of an intelligent and knowing cause. The cause must be always more excellent than the effect; and, therefore, from the various kinds of powers and degrees of excellence and perfection, which visible objects possess; from the intelligence of created beings, which is a real distinct quality or perfection, and not a mere effect or composition of unintelligent figure and motion; from the variety, order, beauty, wonderful contrivance, and fitness of all things to their proper and respective ends; and from the original of motion, the self-existent creating being is demonstrated to be intelligent. 9. The self-existent and original cause of all things is not a necessary agent, but a being endued with liberty and choice. Liberty is a necessary consequent of intelligence: without liberty, no being can be said to be an agent, or cause of any thing; since to act necessarily is really and properly not to act at all, but to be acted upon. Besides, if the supreme cause be not endued with liberty, it will follow, that nothing which is not could possibly have been; that nothing which is could possibly not have been; and that no mode or circumstance of the existence of any thing could possibly have been in any respect otherwise than it now actually is. Farther, if there be any final cause in the universe, the supreme cause is a free agent; and on the contrary supposition, it is impossible that any effect should be finite; and in every effect, there must have been a progression of causes *in infinitum*, without any original cause at all. 10. The self-existent being, the supreme cause of all things, must of necessity have infinite power; since all things were made by him, and are entirely dependent upon him; and all the powers of all things are derived from him, and perfectly subject to him; nothing can resist the execution of his will. 11. The supreme cause and author of all things must of necessity be infinitely wise. This follows from the propositions already established; and the proof *a posteriori*, of the infinite wisdom of *God*, from the consideration of the exquisite perfection and consummate excellency of his works, is no less strong and undeniable. 12. The supreme cause and author of all things must of necessity be a being of infinite goodness, justice, and truth, and all other moral perfections; such as become the supreme governor and judge of the world. The will of a being, infinitely knowing and wise, independent and all-powerful, can never be influenced by any wrong affection, and can never be misled or opposed from without; and, therefore, he must do always what he knows fittest to be done; that is, he must act always according to the strictest rules of infinite goodness, justice, and truth, and all other moral perfections; and more particularly, being infinitely and necessarily happy and all-sufficient, he must be unalterably disposed to do and to communicate good or happiness. See Clarke's Demonstration of the Being and Attributes of *God*, passim.

To this more abstruse argument *a priori*, for the existence of *God*, we may add another, more generally obvious, and carrying irresistible conviction, which is deduced from the frame of the universe, and from the traces of evident contrivance and fitness of things for one another, that occur through all the parts of it. These conspire to prove, that the material world, which in its nature is originated and dependent, could not have been the effect of chance or necessity, but of intelligence and design. The beautiful, harmonious, and beneficial arrangement of the various bodies, that compose the material system; their mutual dependence and subserviency; the regularity of their motions, and the aptitude of these motions for producing the most beneficial effects; and many other phenomena resulting from their relation, magnitude, situation, and use, afford unquestionable evidences of the creating

creating power and wife diſpoſal of an intelligent and almighty agent. The power of gravity, by which the celeſtial bodies perſevere in their revolutions, deſerves our particular conſideration. This power penetrates to the centres of the ſun and planets, without any diminution of its virtue, and is extended to immenſe diſtances, regularly decreaſing, and producing the moſt ſenſible and important effects. Its action is proportional to the quantity of ſolid matter in bodies, and not to their ſurfaces, as is uſual in mechanical cauſes; and, therefore, ſeems to ſurpaſs mere mechaniſm. But however various the phenomena that depend on this power, and may be explained by it, no mechanical principles can account for its effects; much leſs could it have produced, at the beginning, the regular ſituation of the orbs, and the preſent diſpoſition of things. Gravity could not have determined the planets to move from weſt to eaſt in orbits nearly circular, almoſt in the ſame plane; nor could this power have projected the comets with all the variety of their directions. If we ſuppoſe the matter of the ſyſtem to be accumulated in the centre by its gravity, no mechanical principles, with the aſſiſtance of this power, could ſeparate the huge and unwieldy maſs into ſuch parts as the ſun and planets; and after carrying them to their different diſtances, project them in their ſeveral directions, preſerving ſtill the equality of action and reaction, or the ſtate of the centre of gravity of the ſyſtem. Such an exquiſite ſtructure of things could only ariſe from the contrivance and powerful influences of an intelligent, free, and moſt potent agent. The ſame powers, therefore, which at preſent govern the material univerſe, and conduct its various motions, are very different from thoſe which were neceſſary to have produced it from nothing, or to have diſpoſed it in the admirable form in which it now proceeds.

But we ſhall far exceed the proper limits of this article, if confining our obſervation to the earth, our own habitation, we were to enumerate the principal traces of deſign and wiſdom, as well as goodneſs, which are diſcernible in its figure and conſtituent parts, in its diurnal and annual motion, in the poſition of its axis with regard to its orbit, in the benefit which it derives from the light and heat of the ſun, and the alternate viciſſitude of the ſeaſons; in the atmoſphere which ſurrounds it, and in the different ſpecies and varieties of vegetables and animals with which it is repleniſhed. No one can ſurvey the vegetable productions of the earth, ſo various, beautiful, and uſeful, nor the various gradations of animal life, in ſuch a variety of ſpecies, all preſerved diſtinct, and propagated by a ſettled law, each fitted to its own element, provided with proper food, and with inſtincts and organs ſuited to its rank and ſituation, and eſpecially with the powers of ſenſation and ſelf-motion, and all more immediately or remotely ſubſervient to the government and uſe of man, without admiring the ſkill and deſign of the original Former. But theſe are more ſignally manifeſted in the ſtructure of the human frame, and in the noble powers and capacities of the human mind; more eſpecially in the moral principles and faculties, which are a diſtinguiſhing part of our conſtitution, and lead to the perception and acknowledgement of the exiſtence and government of *God*. In thoſe inſtances that have now been recited, and a variety of ſimilar inſtances ſuggeſted by them, or naturally occurring to the notice of the curious and reflecting mind, contrivance is manifeſt, and immediately, without any nice or ſubtle reaſonings, ſuggeſts a contriver. It ſtrikes us like a ſenſation; and artful reaſonings againſt it may puzzle us, without ſhaking our belief. No perſon, for example, that knows the principles of optics, and the ſtructure of the eye, can believe that it was formed without ſkill in that ſcience; or that the ear was formed without the knowledge of ſounds; or that the male and female, created and preſerved in due proportion, were not formed for each other, and for continuing the ſpecies. All our accounts of nature are full of inſtances of this kind. The admirable and beautiful ſtructure of things for final cauſes, exalts our idea of the contriver; and the unity of deſign ſhews him to be one. The great motions in the ſyſtem, performed with the ſame facility as the leaſt, ſuggeſt his almighty power, which gave motion to the earth and the celeſtial bodies, with equal eaſe as to the minuteſt particles; the ſubtility of the motions and actions in the internal parts of bodies, ſhews that this influence penetrates the inmoſt receſſes of things, and that he is equally active and preſent every where. The ſimplicity of the laws that prevail in the world, the excellent diſpoſition of things, in order to obtain the beſt ends, and the beauty which adorns the works of nature, far ſuperior to any thing in art, ſuggeſt his conſummate wiſdom. The uſefulneſs of the whole ſcheme, ſo well contrived for the intelligent beings who enjoy it, with the internal diſpoſition and moral ſtructure of thoſe beings, ſhews his unbounded goodneſs. Theſe are arguments which are ſufficiently open to the views and capacities of the unlearned, while, at the ſame time, they acquire new ſtrength and luſtre from the diſcoveries of the learned. The Deity's acting and interpoſing in the univerſe ſhew that he governs it as well as formed it; and the depth of his counſels, even in conducting the material univerſe, of which a great part ſurpaſſes our knowledge, tends to preſerve an inward veneration and awe of this great being, and diſpoſes us to receive what may be otherwiſe revealed to us concerning him. His eſſence, as well as that of all other ſubſtances, is beyond the reach of all our diſcoveries; but his attributes clearly appear in his admirable works. We know that the higheſt conceptions we are able to form of them are ſtill beneath his real perfections; but his dominion over us, and our duty towards him, are manifeſt. See Maclaurin's Account of Sir I. Newton's Phil. Diſc. book iv. chap. 9.

Thoſe who wiſh to ſee the argument, which has been now ſketched out in ſome of its leading outlines, more fully illuſtrated and urged, may conſult the works of Ray, Nieuwentyt, Pattier in his Matho, Derham, De la Pluche in his Nature diſplayed, &c.

Another argument to prove the exiſtence of *God*, as the creator and governor of the univerſe, may be deduced from the univerſal conſent of mankind, and the uniform tradition of this belief through every nation and every age; it is impoſſible to conceive, that a fallacy, ſo perpetual and univerſal, ſhould be impoſed on the united reaſon of mankind. No credible and ſatisfactory account can be given of this univerſal conſent, without aſcribing it to the original conſtitution of the human mind, in conſequence of which it cannot fail to diſcern the exiſtence of a deity, and to the undeniable traces of his being, which his works afford. Fear, ſtate policy, and the prejudices of education, to which the concurrence of mankind in this principle has been ſometimes reſolved, are founded on this univerſal principle, ſuppoſe its being and influence, and are actuated by it. It is much more reaſonable to imagine, that the belief of a *God* was antecedent to their operation than that it ſhould have been produced by them; and that it was dictated by reaſon and conſcience, independently of the paſſions and policy of men. The uniform and univerſal tradition of this belief, and of the creation of the world by the divine power, affords concurring evidence both of the principle and of the fact.

The exiſtence of *God* is alſo farther evinced by thoſe argumenta which have been uſually alledged to prove, that the world had a beginning, and, therefore, that it muſt have been created by the energy of divine power. In proof of this, the hiſtory of Moſes, conſidered merely as the moſt ancient hiſtorian, deſerves particular regard. His teſtimony is confirmed by the moſt ancient writers among the heathens, both poets and hiſtorians. It may be alſo fairly alledged, that we have no hiſtory or tradition more ancient than that which agrees with the received opinion of the world's beginning, and of the manner in which it was produced; and that the moſt ancient hiſtories were written long after that time. And this conſideration is urged by Lucretius, the famous Epicurean, as a ſtrong preſumption that the world had a beginning:

> —— *Si nulla fuit genitalis origo*
> *Terrarum & cæli, ſemperque æterna fuere:*
> *Cur ſupra bellum Thebanum, & funera Trojæ,*
> *Non alias alii quoque res cecinere poetæ?*

Beſides, the origin and progreſs of learning, and the moſt uſeful arts, confirm the notion of the world's beginning, and of the common æra of its creation; to which alſo may be added, that the world itſelf, being material and corruptible, muſt have had a beginning; and many phenomena occur to the obſervation of the aſtronomer and natural hiſtorian, which furniſh a ſtrong preſumption, that it could have had no long duration, and that it gradually tends to diſſolution. From all theſe conſiderations we may infer the exiſtence, attributes, and providence of *God*.

GOD is alſo uſed in ſpeaking of the falſe deities of the heathens, many of which were only creatures to which divine honours and worſhip were ſuperſtitiouſly paid.

The Greeks and Latins, it is obſervable, did not mean, by the name *God*, an all-perfect being, whereof eternity, infinity, omnipreſence, &c. were eſſential attributes: with them, the word only implied an excellent and ſuperior nature; and, accordingly, they give the appellation *gods* to all beings of a rank, or claſs, higher and more perfect than that of men; and eſpecially to thoſe who were inferior agents in the divine adminiſtration, all ſubject to the one ſupreme.

Thus men themſelves, according to their ſyſtem, might become

become *gods*, after death; inasmuch as their souls might attain to a degree of excellence superior to what they were capable of in life.

The first divines, father Bouhours observes, were the poets: the two functions, though now separated, were originally combined; or, rather, were one and the same thing.

Now the great variety of attributes in *God*, that is, the number of relations, capacities, and circumstances, wherein they had occasion to consider him, put these poets, &c. under a necessity of making a partition, and of separating the divine attributes into several persons; because the weakness of the human mind could not conceive so much power and action in the simplicity of one single divine nature.

Thus the omnipotence of *God* came to be represented under the person and appellation of Jupiter; the wisdom of *God*, under that of Minerva; the justice of *God*, under that of Juno.

The first idols, or false *gods*, that are said to have been adored, were the stars, sun, moon, &c. on account of the light, heat, and other benefits which we derive from them.

Afterwards the earth came to be deified, for furnishing fruits necessary for the subsistence of men and animals; then FIRE and WATER became objects of divine worship, for their usefulness to human life.

In process of time, and by degrees, *gods* became multiplied to infinity; and there was scarce any thing but the weakness, or caprice, of some devotee or other, elevated into the rank of deity; things useful, or even destructive, not excepted.

The principal of the ancient *gods*, whom the Romans called *dii majorum gentium*, and which Cicero calls *celestial gods*, Varro *select gods*, Ovid *nobles dieux*, others *conscious dieux*, were, Jupiter, Juno, Vesta, Minerva, Ceres, Diana, Venus, Mars, Mercury, Neptune, Vulcan, and Apollo.

Jupiter is considered as the *god* of heaven; Neptune as *god* of the sea; Mars as the *god* of war; Apollo of eloquence, poetry, and physic; Mercury of thieves, Bacchus of wine, Cupid of love, &c.

A second sort of *gods*, called *demi-gods*, *semidii*, *dii minorum gentium*, *indigetes*, or *gods* adopted; were men canonized and deified. As the greater *gods* had possession of heaven by their own right; these secondary deities had it by right and donation; being translated into heaven because they had lived as *gods* upon earth.

The heathen *gods* may be all reduced to the following classes.

1. Created spirits, angels, or demons; whence good and evil *gods*; Genii, Lares, Lemures, Typhones, guardian *gods*, infernal *gods*, &c.

2. Heavenly bodies; as the sun, moon, and other planets: also the fixed stars, constellations, &c.

3. Elements; as air, earth, ocean, Ops, Vesta; the rivers, fountains, &c.

4. Meteors. Thus the Persians adored the wind; thunder and lightning were honoured under the name of Geryon; and several nations, of India and America, have made themselves *gods* of the same. Castor, Pollux, Helena, and Iris, have also been preferred from meteors to be *gods*; and the like has been practised in regard to comets: witness that which appeared at the murder of Cæsar. Socrates deified the clouds, if we may give credit to Aristophanes; and the primitive Christians, Tertullian assures us, were reproached with the same thing.

5. They erected minerals, or fossils, into deities. Such was the Baetylus; the Finlanders adored stones; the Scythians iron; and many nations silver and gold.

6. Plants have been made *gods*. Thus leeks and onions were deities in Egypt; the Sclavi, Lithuanians, Celtæ, Vandals, and Peruvians, adored trees and forests; the ancient Gauls, Britons, Druids, bore a particular devotion to the oak; and it was no other than wheat, corn, spelt, &c. that the ancients adored under the names of Ceres and Proserpina.

7. They took themselves *gods* from among the waters. The Syrians and Egyptians adored fishes; and the Tritons, Nereids, Syrens, &c. what were they but fishes? Several nations have adored serpents: particularly the Egyptians, Prussians, Lithuanians, Samogitians, &c.

8. Insects, as flies, and ants, had their priests, and votaries; these among the Thessalians, and those in Acarnania, where bullocks were offered to them.

9. Among birds, the stork, raven, the sparhawk, ibis, eagle, griffon, and lapwing, have had divine honours; the last in Mexico, the rest in Egypt, and at Thebes.

10. Four-footed beasts have had their altars; as the bull, dog, cat, wolf, baboon, lion, and crocodile, in Egypt, and elsewhere; the hog in the island of Crete; rats and mice in the Troas, and at Tenedos; weasels at Thebes, and the porcupine throughout all Zeroaster's school.

11. Nothing was more common than to place men among the number of deities: and from Belus or Baal, to the Roman emperors before Constantine, the instances of this kind are innumerable; frequently they did not wait so long as their deaths for the apotheosis. Nebuchadnezzar procured his statue to be worshipped while living; and Virgil shows that Augustus had altars and sacrifices offered to him, Eclog. i. 6. 7. As we learn, from other hands, that he had priests called *Augustales*; and temples, at Lyons, Narbona, and several other places: and he must be allowed the first of the Romans, in whose behalf idolatry was carried to such a pitch. The Ethiopians deemed all their kings *gods*: the Velleda of the Germans; the Janus of the Hungarians; and the Thaut, Woden, and Atis, of the northern nations, were, indisputably, men.

12. Not men only, but every thing that relates to man, has also been deified: as labour, rest, sleep, youth, age, death, virtues, vices, occasion, time, place, numbers, among the Pythagoreans; the generative power, under the name of Priapus. Infancy, alone, had a cloud of deities; as Vagitanus, Levana, Rumina, Edusa, Potina, Cuba, Cumina, Carna, Ossilago, Statilinus, Fabulinus, &c.

They also adored the *gods* health, fever, fear, love, pain, indignation, shame, impudence, opinion, renown, prudence, science, art, fidelity, felicity, calumny, liberty, money, war, peace, victory, triumph, &c.

Lastly, nature, the universe, or ye *one*, was reputed a great *god*.

Hesiod has a poem under the title of *Theogonies*, i. e. the generation of the *gods*; wherein he explains their genealogy and descent; sets forth who was the first, and principal; who next descended from him, and what alliance each had: the whole making a sort of system of heathen theology.

Besides this popular theology, each philosopher had his system: as may be seen from the Timæus of Plato, and Cicero De Natura Deorum.

Justin Martyr, Tertullian in his Apologetics, and in his book Contra Gentes; Arnobius, Minutius Felix, Lactantius, Eusebius, Pamphilus, & Demonstr. Evangel. St. Augustine De Civit. Dei, and Theodoret Adversus Gentes, shew the vanity of the heathen *gods*.

It is very difficult to discover the real sentiments of the heathens, with respect to their *gods*: they are exceedingly intricate and confused, and even frequently contradictory. They admitted so many superior and inferior *gods*, who filled the empire, that all was full of *gods*. Varro reckons up no less than 30,000 adored within a small extent of ground, and yet their number was every day growing. The way to heaven was so easy for the great men of those days, that Juvenal brings in Atlas complaining he was ready to sink under the load of such a number of new *gods* as were daily placed in the heavens: yet father Montfaucon seems to have proved that *all* the philosophers of antiquity, have acknowledged that there was but one god. Plan. Theol. des Sect. Savantes de la Grece.

GOD, *act of*. See DEIFICATION.

GOD, *peace of*. See PEACE.

GOD, *Son of*. See SON.

GOD, *truce of*. See TRUCE.

GOD, *worship of*. See WORSHIP.

GOD-BOTE, in our *Ancient Saxon Customs*, an ecclesiastical or church fine, for crimes and offences committed against God.

GODDESS, *dea, diva*, a heathen deity, to whom they attributed the female sex.

The ancients had almost as many *goddesses* as gods. Such were Juno, the *goddess* of air; Diana, the *goddess* of woods and chastity; Proserpina, the *goddess* of hell; Venus, of beauty; Thetis, of the Sea: such also were Victory, Fortune, &c.

Nay, they were not contented to make women gods, and admit both sexes into the roll; but they had also hermaphrodite gods. Thus Minerva, according to several of the learned, was both man and woman, and worshipped both under the appellation of Lunus and Luna. Mithras, the Persian deity, was both god and *goddess*; and the sexes of Venus and Vulcan are very dubious: whence, in the invocations of those deities, they used this formula: Be thou god, or *goddess*: as we learn from A. Gellius.

It was a privilege peculiar to *goddesses*, that they might be represented on medals, naked. The imagination, it was supposed, must be awed, and kept from taking liberties, by the consideration of the divine character.

GOD-FATHERS, and GOD-MOTHERS, persons who direct and attend at the baptism of infants, or other persons; and who give the name.

The number of *god-fathers* and *god-mothers* is now reduced to three in the church of England, and two in that of Rome: anciently, they had as many as they pleased.

The Romanists have alſo *god-fathers* and *god-mothers*, at their confirmation. They even give *god-fathers*, &c. to bells, at their baptiſm.

Among the ancients it was the cuſtom for perſons of quality to have others of like quality cut their children's hair, the firſt time; by which they became reputed a ſort of *god-fathers*: and the like was practiſed with regard to the hair of the beard.

GOD-FATHER was alſo a name anciently given to a kind of ſeconds, who attended and aſſiſted the knights in tournaments, or ſingle combats.

The *god-fathers* of duels were a kind of advocates, who were choſen by the two parties, to repreſent the reaſons of their combat to the judges.

Something of this kind was long retained at ſolemn carrouſals. There were two, or more, in each quadrille. See QUADRILLE.

The inſtitution of *god-father* and *god-mother*, *patrini* and *matrini*, is originally Roman. They are ſaid to have been people, who, in the games of the Circus, attended the chariots, ſhews, and images of the gods. Cicero makes mention of them, in his oration De Haruſpicum Reſponſis. Their office was much like that of the children in ſome Ruſſian ceremonies, who are dreſſed in the habit of angels, to ſtrew flowers, bear incenſe-pots, lights, &c. and accompany the relics and images of ſaints.

GOD-GILD, in our *Ancient Cuſtoms*, that which is offered to God, or for his ſervice.

GODWIT, in *Ornithology*, the SCOLOPAX *aegocephala* of Linnæus, the *aegocephalus* of other authors, and called alſo the *yarwhelp* or *ſpoonbill*, is a ſpecies of birds, taken in the fens, in the ſame ſeaſon and in the ſame manner with the ruffs and reeves, and, when fattened, eſteemed a great delicacy. This ſpecies weighs 12½ ounces; the length is ſixteen inches; and the breadth twenty-ſeven; the bill is four inches long, turns up a little, being black at the end and in the other part of a pale purple: from the bill to the eye is a broad white ſtroke; the feathers of the head, neck and back are of a light reddiſh brown, marked in the middle with a duſky ſpot: the belly and vent feathers are white; the tail regularly barred with black and white; the ſix firſt quill-feathers are black with their interior edges of a reddiſh brown: the legs of ſome are duſky and of others a greyiſh blue; and the exterior toe is connected as far as the firſt joint of the middle toe with a ſtrong ſerrated membrane. The male is diſtinguiſhed from the female by ſome black lines on the breaſt and throat. Theſe birds appear in ſmall flocks on our coaſt in September, and continue with us the whole winter: they walk on the ſands like the curlew, and feed on inſects. Pennant.

GODWIT, *red*, or SCOLOPAX *Lapponica* of Linnæus, is larger than the former; the bill is ſomewhat ſhorter but of the ſame figure; the lower half is black and the upper yellow; the head, neck, breaſt, ſides, ſcapulars, and upper part of the back are of a bright ferruginous colour; the head is marked with oblong duſky lines; the neck is plain; the breaſts, ſides, ſcapulars, and back varied with tranſverſe black bars, and the edges of the feathers with a pale cinerilous brown; the middle of the belly is white, marked ſparingly with ſimilar ſpots; the legs are black and four inches long; and the thighs above the knees are naked for the ſpace of 1½ inch. This is not a very common ſpecies in England. Pennant.

GODWIT, *laſſer*, the totanus of Aldrovand, is ſometimes called the *flama-plover*, and at Venice the VETOLA.

GOGET, in *Ichthyology*, a name frequently uſed for the GOBIUS *niger* of Linnæus, the ſea-gudgeon or rock-fiſh, and by which it is known in moſt parts of the world.

This is a long and ſlender fiſh, of a rounded not flat body, and ſeldom exceeds ſix inches in length. Its colour is very various, being either a brown variegated with white and yellow, or a bluiſh white with lines of a faint olive-colour, and black ſpots. The dorſal and anal fins are of a pale blue, the rays being marked with ſmall black ſpots. The firſt dorſal fin conſiſts of ſix rays; the ſecond of fourteen; the pectoral fins of ſixteen or ſeventeen, cloſely ſet together; the middle being the longeſt and the others on each ſide gradually ſhorter. *Tab. of Fiſh.* N° 8.

The belly-fins join together into one, and make a ſort of funnel-ſhaped hollow, by which the fiſh is ſuppoſed to apply itſelf, and ſtick faſt to the rocks, whence it has its name of rock-fiſh. It is very ſoft and ſlippery, yet is covered with ſcales, but they are very ſlender and ſoft. It is caught about the Engliſh and Italian ſhores, and lives in ſhallow water. It is conſtantly in the markets of Rome, &c.

GOGGLES, in *Surgery*, are inſtruments uſed for curing EQUINITAS, or that diſtortion of the eyes, which occaſions this diſorder. They are ſhort conical tubes, compoſed of ivory ſtained black, with a thin plate of the ſame ivory fixed in the tubes near their anterior extremities. Through the centre of each of theſe plates is a ſmall circular hole, about the ſize of the pupil of the eye, for the tranſmiſſion of the rays of light. Theſe *goggles* muſt be continually worn in the day-time, till the muſcles of the eye are brought to act regularly and uniformly, ſo as to direct the pupil ſtrait forwards; and by theſe means the cure will be ſooner or later effected. Warner on the Eyes, p. 32.

GOHDAKADURA, in *Botany*, a name given by ſome authors to the tree which produces the *nux vomica*.

GOHKATHU, in *Botany*, a name given by ſome authors to the tree which produces the gamboge, or *gutta gamba* of the ſhops.

GOING, in the *Manage*, called in French *allure*, is the pace or gait of a horſe.

GOLD, *aurum*, a yellow metal: the heavieſt, pureſt, moſt ductile, and ſhining; and, on thoſe accounts, the moſt valuable of all metals.

The yellow colour of *gold* is rendered paler by fuſion with borax; but this may be prevented or corrected by fuſion with nitre, or ſal ammoniac. The colour of *gold* is heightened by an alloy of copper, and this property of copper has given riſe to ſundry proceſſes for exalting the colour of this noble metal. Other metals render it paler. The chemiſts call *gold*, *ſol*, the ſun; to denote its pre-eminence over the other metals, which are called by the names of the planets. Its ſymbol, or character, is ☉; which, in their hieroglyphical way of writing, denotes perfection, ſimplicity, ſolidity, &c.

The weight of *gold* is to that of water, as 19637 to 1000. Fine *gold* immerſed in water, weighs near one nineteenth part leſs than in air, and conſequently it is upwards of nineteen times heavier than its own volume of water.

The *ſpecific* GRAVITY of *gold*, or its comparative weight with an equal volume of water has been variouſly aſſigned: ſome have made it 19,637, others, 19,640, and in the Swediſh Tranſactions it is made no leſs than 20,000; that of water being 1,000. But from the experiments of Mr. Ellicott, it does not appear to have exceeded 19,4075; and from thoſe of Dr. Lewis, on the pureſt *gold*, well hammered, its gravity is ſtated between 19,300 and 19,400. In all experiments of this kind, the reſult ſhould be ſpecified with an account of the ſenſibility of the balance, and the quality and warmth of the water. An increaſe of heat rarefying water more than it does *gold*, the *gold* muſt turn out proportionably heavier than an equal volume of the expanded fluid; and this difference is more conſiderable than it has generally been ſuppoſed. From freezing to boiling water, or by an augmentation of heat equivalent to 180° of Fahrenheit's thermometer, Dr. Lewis found that a rod of *gold* was lengthened about one part in 500, and conſequently its volume increaſed about one part in 233, while the volume of water is increaſed one twenty ſixth or more; hence it appears, that by an augmentation of 40° of the thermometer, or from a little above freezing to the ſummer heat, the volume of *gold*, if its expanſion be uniform, is increaſed one part in 1048, and that of water one in 117; and the gravity of *gold*, weighed in the water ſo warmed and expanded, ſhould be greater than when the *gold* and water are 40° colder, in the proportion of about 19,265 to 19,400: and this calculation gives a difference, in the gravity, of 0,034 for every 10° of the thermometer; but ſome trials ſeemed to make it greater. It has been imagined, that the comparative gravity of *gold* to braſs weights, which are more than double in volume to an equal weight of *gold*, muſt be ſo far influenced by the variable gravity of the atmoſphere, that there muſt be an advantage in buying *gold* by weight when the air is lighteſt. But Dr. Lewis obſerves, that this difference appears too inconſiderable to be regarded in a commercial view. For the loſs of weight of the two metals in the air being as much leſs than their loſs in water as air is lighter than water; and air, as appears from an experiment of Mr. Hawkſbee, being in its lighteſt ſtate about a 937th, and in its heavieſt ſtate about an 848th part of the weight of water; it will be found on calculation, that the *gold* preponderates above the braſs, in the heavieſt more than in the lighteſt air, only by one part in 145000, or one grain in about 302 ounces; which is a difference too minute to be ſenſible in the niceſt balance. If the mean gravity of *gold* be reckoned 19,300, as a cubic inch of water weighs about 254 grains, a cubic inch of *gold* will conſequently weigh about 4902 grains, or 10 ounces, 102 grains. The pound weight, or twelve ounces, Troy, of *gold*, is divided into twenty-four carats.

The value of *gold* to that of ſilver, was anciently only as twelve

twelve to one. Indeed, this proportion varies as *gold* is more or less plentiful: for Suetonius relates, that Cæsar brought such a quantity of *gold* from Italy, that the pound of *gold* was only worth seven pounds and a half of silver. In our coinage the value of fine *gold* to fine silver is as $15\frac{1}{2}$ to 1. See STANDARD. Sir Isaac Newton observes, in a representation to the lords of the treasury in the year 1717, that in the mints of Spain and Portugal, the value of *gold* is sixteen times that of silver; but that in those countries, payments in silver bearing generally a premium of six per cent. the proportion may be considered as fixed by commerce at $15\frac{1}{16}$ to 1; that in the other parts of Europe, the value of *gold* is at most fifteen, and in China and Japan but nine or ten times that of silver; so that *gold* is rated higher in England than in any other part of Europe, and higher in Europe than in the Eastern countries. Hence, in great measure, arise the profits of exchanging *gold* for silver in one place, and re-exchanging them in another: and hence the greater disparity between the relative quantities of *gold* and silver in one commercial nation than in another; this metal being brought in most abundance which is rated highest in proportion to the other, and that which is rated lowest being drained away. There are various ways of determining the fineness of *gold*; or the proportion of alloy which it contains. Those who are used to this business can judge nearly the proportion of alloy from the colour of any given mass, provided that the species of alloy be known. For the method of doing this, see TOUCH-*needles*. The great excess of the weight of *gold*, above that of the metals used for its alloy, affords another method of determining the quantity of alloy in any given mass, where the species of alloy is known. Thus fine *gold* loses in water one grain in every 19,3 nearly; and fine silver loses one grain in about eleven; from whence it is easy to find the loss of any number of grains of each, and consequently of any assignable mixture of the two metals. Thus, fifty grains of *gold* will lose above $2\frac{1}{2}$, and fifty grains of silver somewhat more than $4\frac{1}{2}$; so that a mixture of equal parts of the two will lose above seven in a hundred, or one in fourteen. A mixture of *gold* with half its weight of silver will lose one part in 15,4; with a third of silver one in 16,2, with a fourth, one in 16,7; and with an eleventh of silver, which is the standard proportion of alloy, one in 18,1. On this principle, the specific gravity, or proportional loss in water, of *gold* alloyed with different quantities of silver, copper, and mixtures of both, may be computed and formed into tables for use. The accuracy of this method, it should be observed, depends on the supposition, that each of the two metals, that are melted together, retains its own proper gravity, which is the case in mixtures of *gold* and silver; but *gold* and copper, melted together, are specifically lighter than if they were weighed separately; and this also is the case of mixtures of *gold* with zinc, tin, iron, and platina; but the reverse happens in mixtures of it with lead and bismuth. It appears, therefore, that the hydrostatic balance cannot discover, with certainty, the exact fineness of *gold*, unless when silver is the metal mixed with it.

GOLD, *alchimical history of*. See PHILOSOPHER'S *stone*, and TRANSMUTATION.

GOLD, *chemical history of*. The first characteristic or property of *gold* is, that it is the heaviest of all bodies: so that whoever would make *gold*, must be able to add the weight of other matters, and make them equiponderate with *gold*.

In every mass of matter, therefore, heavier than mercury, there must of necessity be a share of *gold*; there being no body in nature, known till of late years, of intermediate gravity; i. e. no body whose gravity is to that of *gold*, more than as fourteen to nineteen.

The discovery of the ponderous metal PLATINA has now afforded an exception to this long received axiom, and shewn that weight alone is no criterion of *gold*; for pure platina, perfectly void of *gold*, is nearly as ponderous as *gold* itself.

Its second character is, that of all known bodies it is the most ductile and malleable, and of all bodies its parts have the greatest degree of attraction, i. e. they cohere with the greatest force. Our gold-beaters and wire-drawers furnish us with proofs of this property. They every day reduce *gold* into leaves or lamellæ, inconceivably thin; yet without leaving the least aperture, or chasm, visible to the best microscope, or even pervious to the light. See this property considered more at large under the article DUCTILITY.

The tenacity of the parts of *gold* is also much greater than that of any other metal; for five hundred pounds can be supported by a wire of one-tenth of an inch in diameter made of *gold*, but not of any other metal. The malleability of *gold* is very little affected by a mixture of silver; it is not much diminished by copper, which renders it harder than silver does; and next to these two metals, platina injures its malleability the least. But all the rest of the metallic bodies render it brittle in different degrees; and its malleability is destroyed by fumes of lead, and of most other metallic substances, but may be recovered by fusion with nitre. It has been said by many that this property of *gold* is injured by the fumes of charcoal; but Dr. Lewis believes this to be a mistake. The malleability of *gold* is also diminished by cooling it, in a state of fusion, too hastily; for preventing which, artists heat the mould into which the *gold* is to be cast. Mr. Boyle mentions an anti-elixir, which he tried; that is, one that would debase *gold*, and which changed its malleability, colour, homogeneity, and specific gravity; so that though the powder did not weigh the thousandth part of the *gold*, yet the specific gravity of the metal to which it was debased, was to that of water but as $15\frac{1}{2}$ to 1, instead of 19 to 1. Boyle's Works abr. vol. i. p. 78. It is observed by Dr. Lewis, that, though the expansion of *gold* is less than that of other metallic substances with *small degrees of heat*, it nevertheless expands more than most of the other metals, when fused; and as it thus shrinks more when it becomes solid, it is less capable of receiving sharp and perfect figures, when cast into moulds, than silver, copper, lead, and tin, which do not shrink so much, and much less than iron and bismuth, which expand in passing from a fluid to a solid state. *Gold*, when melted with a low white heat, has a bright bluish green colour.

It is the received opinion, that whatever has been done to this metal, the common way of purifying it by the cupel restores it easily to itself again; but this is not always so certain, or so easy as is generally imagined. Mr. Homberg put into the cupel an ounce of *gold*, which he had used in several chemical experiments, in order to restore it to its original state; but after four times cupelling it, he found, that whatever quantity of lead he used, still the metal, though of the right and beautiful colour, was brittle, and not at all in the ductile state of pure *gold*. Finding, therefore, that lead would not answer his purpose, he incorporated the *gold* with four times its quantity of silver; and having performed the operation of the depart in the common manner, he fused it with borax; but after all this the *gold* was as brittle as before, though still of the same beautiful colour. He then melted it again without any addition, but still it remained in the same brittle state. His next trial was by antimony, not doubting but that the particles, whatever they were, that had stood the operation of the depart, and of lead, would be absorbed by this powerful semi-metal, and the *gold* left in its natural malleable state. He melted it twice to this purpose with eight ounces of antimony; but after separating the antimony, and then melting the *gold* several times with salt-petre, and many times without any mixture, it was found of the most perfect and beautiful colour imaginable, but still brittle, and not in the least malleable. Surprised to see all the common methods fail, he melted it again with six ounces of antimony, and afterwards melted this regulus with three times its own weight of lead, and set the whole in a cupel in a proper degree of fire, to evaporate both the antimony and the lead. But when the fire was out, he was surprised to find the *gold* covered with a brownish substance, resembling a mushroom, which fell to powder on being touched by the fingers. The *gold* itself was become of a grey colour, and was full of wrinkles on the upper surface, from whence this fungous matter had been thrown out; but on the under surface, where it stuck to the cupel, it was still of a fine and beautiful *gold* colour. He then melted several times the *gold* and the fungous substance together, and every time there appeared the same sort of fungous crust at the top. At last he gathered this fungous substance carefully off from the *gold*, and then melting the metal by itself, there was no more any fungous matter thrown out upon it, but only a thin layer of a powder of the same nature and colour with the former. Three times it was melted, and at every time threw off a quantity of this powder; and after this, being fused with borax, it at length became perfect malleable *gold*. He then fused together the fungous matter, and all the quantities of powder which he had saved, there appeared a new fungus on the matter, and that for several times melting; but at last this disappeared, and there was found a small lump of pure *gold* in the cupel. It is not easy to guess at the cause of this obstinate brittleness of the *gold*, because it had passed several experiments, and been mixed with several salts and several metals, particularly at last with iron and with emery. The emery seemed most to be suspected of the cause; but this brittleness cannot be given to *gold* by emery alone, and must have been owing to the mixed effect of some of the salts and emery together, as by means of the salts, the particles

of emery are thrown farther, and more intimately mixed with thofe of the *gold* than they could otherwife be. We have been told of the degradation of *gold*. This *gold* would have been declared degraded, and robbed of one of its greateft qualities, its malleability, had it fallen into any hands but thofe of fo great a chemift; and it is much to be doubted, whether Mr. Homberg would not have been able to reduce the degraded *gold* of any other chemift, and reftore it to its natural ftate and purity, though the common methods of operating on it fhould all have failed, as they did in this cafe. Mem. Acad. Par. 1693. The third character of *gold* is its fixednefs in the fire; in which it exceeds all other bodies. This property feems to refult from the homogeneity and equality of its parts, which equally aid and fupport each other, and have equal pores, or interftices, through which the fiery corpufcles find an eafy paffage. The prince of Mirandola, Mr. Boyle, and moft other chemifts, furnifh divers experiments to illuftrate this wonderful fixity. After laying a quantity of *gold* two months in the ftrongeft heat imaginable, it is taken out without any fenfible diminution of weight; whereas the other metals, plating and filver excepted, are foon deprived by fire of their metallic appearance, and either diffipated in flames, or changed into an earthy or glaffy form.

It muft be added, however, that in the foci of the large BURNING-*glaffes* of Meff. Tfchirnhaufen and Villette, even *gold* itfelf volatilizes and evaporates. After this manner, we are told from the Royal Academy at Paris, a quantity of pure *gold* was vitrified; being firft fufed in a fort of cafe, which emitted fumes, and loft of its weight. But the fame cafe, fufed again with a quantity of greafe, was reftored into *gold*.

Mr. Homberg found by experiment, that *gold* properly managed in the focus of the great burning glafs, after the evaporum of fome of its conftituent parts, was vitrifiable, like other metals. That part of this metal which flies off in fume, he fays, is the mercury which entered its compofition, and what then remains, which is an earth penetrated by fulphurs, runs into glafs, as all other fubftances of a like kind muft with a like fire. But he ought to have previoufly afcertained the purity of the *gold* which he employed; for want of which the glafs produced in this experiment might proceed from copper, or other metal, with which the *gold* might have been alloyed. Befides, as the fubftances expofed to the focus of the burning glafs are laid upon a piece of charcoal, and that charcoal is always in part reduced to afhes about the body in trial, and thefe afhes often fly over and all about it; it was objected to Mr. Homberg, by fome who faw his experiments, that thefe afhes alone vitrified on the *gold*, and not any part of the *gold* itfelf; but Mr. Homberg replies, that if this were the cafe, thefe afhes would alfo be vitrified upon filver in the like trials and circumftances, and give an appearance of the filver's vitrifying; but often repeated experiments have proved, that filver expofed to the focus of the burning glafs, gives not the leaft fign of vitrification in any circumftance, unlefs it has been refined with antimony; that is to fay, unlefs there has been given to it by art more fulphurs than it is naturally poffeffed of; but in that cafe, thefe unnatural abundant fulphurs will always vitrify a part of its earth. Mem. Acad. Par. 1702. 1707.

With regard to this experiment, Dr. Lewis obferves, that the afhes might eafually have been accumulated on the metal, fo as to produce a fenfible vitrification, in one inftance, without being fo in another, and that, at beft, it is too imperfect for any ftrefs at all to be laid upon it. The fame experiment has been repeated by others without fuccefs; and though the *gold*, expofed to the focus of a burning lens, does really decreafe in weight, this diminution appeared to be owing to the feparation of minute globules in fubftance, which were found to be perfect unchanged *gold*. The true alchemifts have made no doubt of the poffibility of decompofing, or entirely deftroying *gold*, and of tranfmuting the baler metals into this; their books are filled with various proceffes for thefe purpofes; notwithftanding which, the producibility and deftructibility of *gold* ftill continue problems in chemiftry: not is there any experiment from which the poffibility of either can be inferred; though there is reafon to believe, that its refiftance to all our operatons is owing to our inability to raife a fufficient heat.

Its fourth character is, that it is not only unalterable by air and water, but that it refifts, while its aggregation is entire, the action of the ftrongeft fimple chemical menftruums, either in the dry or humid way. It is faid not to be foluble by the ftrongeft mineral acids, when they are pure, nor by fulphur, nor by alkalis. However, though it has been generally fuppofed by the affayer and refiner, that *gold* is abfolutely indiffoluble by the nitrous acid; yet Dr. Brandt has lately publifhed, in the Swedifh Tranfactions for the year 1748, a difcovery of certain circumftances, in which *gold* is diffolved by this acid in conliderable quantity. For, having boiled a mixture of *gold* and filver, amounting to about fifteen pounds, in which the proportion of the filver, containing a little copper, to the *gold*, was as 16 to 3, with frefh portions of ftronger and ftronger aqua fortis, in a glafs body, to which was fitted a head and recipient for collecting the acid vapours that arofe; he poured off the folution from the *gold* when all the filver and copper were nearly diffolved, and boiled down the next portion of aqua fortis, till the matter at the bottom appeared like a dry falt. He then added more aqua fortis, which, after boiling for fome time, appeared yellow, and was poured off into a feparate glafs; this yellow aqua fortis he afterwards ufed for diffolving fome filver, and found a conliderable quantity of *gold* at the bottom of the glafs, though the filver had been very carefully purified from *gold*. In this experiment, pure filver, which exhibited no appearance of *gold* with common aqua fortis, precipitated from the yellow aqua fortis a fpongy lump of *gold*. In keeping, a part of the *gold* feparated fpontaneouffy in form of a brown powder: after it had been long kept, and depofited much of its *gold*, it was found on an affay to contain more *gold* than filver, in the proportion of 19 to 12. In this ftate, a quantity of it, fufficient to diffolve four parts of filver, yielded during the diffolution one part of *gold*; fo that the nitrous acid is capable of diffolving above one fourth part as much *gold* as of filver. This experiment affords a neceffary and ufeful caution to thofe that are concerned in the parting of gold and filver by aqua fortis.

Gold is faid to be diffolved by leveral compound menftrua: as, by the marine acid mixed with a fmall proportion of fpirit of urine; by a mixture of the vitriolic acid with the fame urinous fpirit; by a mixture of the vitriolic acid with a little fixt alkaline falt; by the vapour which arifes during the effervefcence of the vitriolic acid with fixt alkaline falt, collected by diftillation; by a fpirit, prepared by faturating the vitriolic acid with volatile alkaline falt, exficcating the mixture, diffolving it in twice or thrice its quantity of aqua fortis, and diftilling the folution. But Dr. Lewis could not difcover, in any of his experiments, that any of thefe liquors had *any action* on *gold*. But the moft effectual menftruum of *gold* is AQUA *regia*, which, in a moderate heat, readily and totally diffolves it into a tranfparent yellow liquor, and, therefore, ferves to feparate *gold* from filver. Another folvent of *gold* is a combination of fulphur with fixed alkali, called liver of fulphur. See REFINING.

Nevertheleſs, though a mafs of *gold* refifts the action of fimple folvents, we muft not conclude, that it is abfolutely incapable of folution by any of them. An inftance to the contrary has been already produced; and Mr. Margraaf has difcovered, that this metal, precipitated by an alkali from its folution in aqua regia, is then rendered foluble by any, even of the vegetable acids. See MERCURY and SILVER.

Befides, *gold* diffolved in aqua regia is not precipitated, when the proportions of the two acids of this compound menftruum are changed, by adding to this another any quantity of nitrous or marine acids. Farther, *gold* may be diffolved in alkali, by the procefs of the martial alkaline tincture of Stahl; that is, by pouring into a concentrated folution of fixed alkali in water, a fmall quantity of folution of *gold* in aqua regia, in which the acids are not too much faturated, the *gold* will be quickly feized and diffolved by the alkali.

A folution of *gold* in aqua regia affords a very curious object for the microfcope. Mr. Leewenhoeck took great pains to obferve the configurations it would put on in its concretions: he found, that in warm weather, if a drop of the folution was laid on a clean glafs, and examined by the microfcope, the falts foon congulated, but appeared very irregular in their manner of concretion. They fometimes affumed a regular hexangular form, but more frequently they were rendered irregular, by the application of other fubftances, in form of fmaller cryftals upon them. One thing in this is very remarkable, that is, the cryftals formed at different times feem very differently impregnated with the metal, thofe which concrete firft being ufually large, and perfectly clear and tranfparent, and thofe which afterwards form themfelves upon thefe and alter and injure their figures, being fmaller and feemingly much more impregnated with the metal, as being all of a fine *gold*-yellow. Sometimes alfo it happens, that the fmall falts fated with the particles of the *gold* fhoot firft, and when the other clear and tranfparent cryftals of falt form themfelves afterwards, it not unfrequently happens that they form about the others, and inclofe them within their own bodies. Thus it is not uncommon to fee one of thefe large and tranfparent

cryſtals with a ſmall *gold*-coloured cryſtal immerſed in its centre.

This is a very elegant and entertaining ſight by the microſcope, but it is only to be obſerved in dry ſeaſons, for in moiſt weather the cryſtals either do not form themſelves at all, or elſe it is done but very confuſedly, and they melt and diſſolve away on the acceſs of freſh damp air.

If a ſmall piece of *copper* be put into this ſolution of *gold* in aqua regia, the liquor immediately operates upon it and not only diſſolves the copper, but precipitates the *gold* it had before held in a ſtate of ſolution upon the ſurface of the copper, in the place of what copper it had taken away. The ſame thing happens when a piece of copper is put into a ſolution of ſilver in aqua fortis, but in this laſt caſe the effect is more beautiful; for the ſilver particles precipitated on the copper arrange themſelves in the form of trees and ſhrubs, like the Arbor Dianæ; but in the caſe before us, the *gold* is only precipitated in form of irregular filaments, or ſmall granules, and ſeems rather to imitate that proceſs obſerved in the famous water of the Zinneat, or Cement ſprings in Hungary; where the water being highly impregnated with a ſolution of blue vitriol, containing a very large portion of copper, if a piece of iron be put into it, immediately it works upon the iron, and diſſolving it, precipitates copper in ſmall irregular granules in its place: ſo that, in the opinion of the vulgar, the copper is made of the iron, but in reality the iron is all diſſolved, and the copper left in a ſolid form by the menſtruum which diſſolved it; as in this experiment, the copper put into the ſolution of *gold* is diſſolved, and taken up into the liquor, and the *gold* which was before diſſolved is precipitated in its place.

If the aſſiſtance of art be called in, and the ſolution of *gold* be made according to the rules of chemiſtry in a ſand heat, and the menſtruum ſo ſated with it, that it can diſſolve no more, then it readily ſhoots into cryſtals, on being expoſed to dry in drops before the microſcope on plates of glaſs; and the cryſtals which it forms are in this caſe all of one kind, all ſated with *gold*, of a regularly angular figure, and their angles very ſharp.

Theſe cryſtals appear only like ſo many pieces of pure *gold*, of a fine luſtre and brightneſs, and ſeem maſſes of native *gold*, of this form juſt taken from ſome mine. In order to procure theſe *gold* cryſtals as regularly formed as can be, the ſmall drop, laid on the plate of glaſs, muſt be poured off again at one ſide, and by this means the liquor being ſpread extremely thin, the cryſtals will be formed extremely regular; but then they will be ſo ſmall, that they are only viſible through very powerful glaſſes: when thus managed, however, they ſhew their true form, which is regularly hexangular, but that not in form of a column, as in the hexangular cryſtals; but in a ſhort and thick maſs, reſembling a die, only more long-ſhaped, not ſo exactly ſquare. Notwithſtanding that theſe ſmall cryſtals are yellow, they are as tranſparent as cryſtal, and the liquor remaining about them is alſo yellow and tranſparent. Some of theſe cryſtals, though of the ſame figure with the others, appear not of the ſame even and plain ſtructure, but are plainly ſeen to be formed of a great number of rings, or concentric circles, extended round each other. Copper being put into this ſolution, ſo highly fated with *gold*, is not preyed upon ſo faſt as in a weaker ſolution; ſome few air-bubbles, however, are driven to the ſurface, but without any great effect, but if the ſolution be diluted with a little water, the acid then preys with violence upon a piece of copper put into it. A part of the copper is ſoon diſſolved, and the liquor becomes green, and a ſmall portion of the *gold*, out of the ſolution, is precipitated on the copper, in the place of that part of it which was diſſolved. In this caſe alſo the *gold*, in ſome meaſure, emulates the appearance of the ſilver in its concretion; for though it does not form regular trees and branches, it forms long and ſlender filaments, and theſe do not look of a pure fine yellow, or like pure *gold*, but ſeem dulky, and to have ſome copper among them.

If a ſmall parcel of this ſolution be evaporated on a glaſs plate over a gentle heat, the nature of the metal, and its effects on vitrified bodies, are more eaſily diſcovered than one would expect in ſuch ſmall quantities. Where the liquor has lain the thineſt in this caſe, the glaſs is tinged red by the entrance of the particles of *gold* into its ſurface, which they do eaſily, becauſe in thoſe places where the liquor lay thin, they formed themſelves into extremely minute concretions, according to the foregoing obſervations, and it is well known, that red is the colour which *gold* imparts to the earth to cryſtals and other ſtones, and in the experiments of the chemiſts, to glaſs of any kind. In ſuch places as the liquor has lain thicker in, and has been conſequently evaporated in larger quantity, and from a larger portion of the *gold*, the glaſs is not tinged red, but there is ſeen a reſiduum of the ſolution ſticking to it: this, however, is not formed into cryſtals, but is in this caſe pure *gold*, left from the evaporation in its proper metalline form. This, however, was in ſuch minute concretions, that where they lay ſingle, or ſeparate, they were not viſible, according to Mr. Leewenhoeck's account, to the naked eye, and he computes that many thouſand millions of them were not equal in ſize to a ſingle grain of ſand: in moſt places they were not, however, thus ſeparate, but were formed into oblong and ſtellate concretions, which were ſometimes ſimple, and ſometimes ramoſe, and the microſcope ſhews theſe concretions very elegantly, ſome in form of ſimple threads, ſome of branches of trees or plants.

The denſity of *gold* is no way better ſeen than in this experiment; for though it may eaſily be conceived, that ſuch particles of theſe as were but of a thouſand millionth part, or much leſs than that, of the bigneſs of a grain of ſand, muſt needs be of an almoſt inconceivable thinneſs, yet not the ſmalleſt of theſe would tranſmit any light through it, but all were as perfectly opake as a piece of sheet lead. A ſmall drop of a ſolution of *gold* in aqua regia being laid over a ſtrong fire, approaching it by degrees, till being expoſed to its utmoſt force, both the *gold*, and the glaſs on which it lies, begin to melt; in this caſe the *gold* is found concreted in like manner into filaments compoſed of globules, or of particles nearly round; and if it be taken from the fire juſt at that time when the glaſs only begins to *run*, it adorns to the microſcope a very diſtinct way of obſerving the ramifications of the *gold* and ſilver-ores in their firſt ſtate, and ſhews how they are formed. Phil. Tranſ. N° 286.

Solutions of *gold* in the pure marine acid, and in mixtures of the pure acids of nitre and ſea ſalt, are not made to cryſtalize without great difficulty; in order to which, the liquor ſhould be evaporated, till only about one half of it remains, and then ſet by in the cold, with the addition of a few drops of pure ſpirit of wine. The cryſtals obtained from high-coloured ſaturated ſolutions are generally of a red colour, and ſometimes, as it has been ſaid, of a deep ruby red. If any light eſſential oil be poured upon a ſolution of *gold* in aqua regia, and the mixture be ſhook, the *gold* will paſs into the oily matter, float with it upon the ſurface, and be kept for a little time diſſolved by it's mean; however, will gradually ſeparate, and be thrown off to the ſides in bright yellow films, which on ſhaking the veſſel fall to the bottom. Æther, poured on in the ſame manner, will float diſtinct on the ſurface, become yellow by imbibing the *gold*, as the yellow tinge of the acid diminiſhes, keep it permanently diſſolved, and, when loaded with the ponderous metal, continue ſtill to float upon the acid; and, as *gold* is the only one of the known metals, which the ether takes up from acids, this fluid affords a ready method of diſtinguiſhing *gold* contained in acid ſolutions. See Aurum *potabile*.

Liquors containing a groſſer inflammable matter, as wine, vinegar, ſolution of tartar, are likewiſe found to extricate *gold* from aqua regia in its metallic form; but with this difference from the preceding, that the *gold*, inſtead of floating on the ſurface, falls generally to the bottom. *Gold* may be precipitated from ſolutions in aqua regia by adding the ſolution of any fixt alkaline ſalt, or a volatile alkaline ſpirit, in ſufficient quantity to ſoſiate the acid; the mixture will become turbid, and after ſtanding for ſome hours, the *gold* will fall to the bottom, in form of a brown-ith yellow muddy ſubſtance, retaining ſome of the ſaline matter. To accelerate the precipitation, the ſolution ſhould be diluted with three or four times its quantity of water, or more; and the alkaline liquor ſhould be added gradually, and in ſmall quantities. If the aqua regia has been prepared with ſal ammoniac, or if the precipitation is performed with a volatile alkali, we ſhall have the *fulminating gold*, or Aurum *fulminans*. Farther, all the metallic bodies that diſſolve in aqua regia, plating excepted, precipitate *gold* from it. Some of them precipitate it alſo, when they are previouſly diſſolved in other acids, and even in aqua regia itſelf. The precipitate occaſioned by adding tin is the moſt remarkable of theſe. A plate of pure tin, put into a ſolution of *gold*, largely diluted with water, changes the yellow colour of the liquor into beautiful purple or red; and, by degrees, a powder of the ſame colour ſlowly ſubſides, and leaves the menſtruum colourleſs. Solutions of tin, made in aqua regia, have the ſame effect with tin itſelf, with regard both to the precipitation and the colour; and hence characters, drawn on paper with a diluted ſolution of *gold*, not viſible when dry, become immediately red or purple on paſſing over them a diluted ſolution of tin. On dropping a ſolution of ſilver into a ſolution of *gold*, both metals precipitate; the ſame double precipitation happens,

happens, on mixing folution of *gold* with folution of lead in aqua fortis. Pure fulphur has no action on *gold*. See REFINING. However, it unites perfectly, as we have already obferved, with the *hepar fulphuris*, or liver of fulphur. The addition of any acid to this folution, abforbing the alkaline falt, precipitates the *gold* united with the fulphur; and the fulphur may be diffipated by fire, or more readily feparated, by adding a little copper for abforbing the fulphur. Copper and iron likewife added to the mixture of *gold* and *hepar* in fufion, will precipitate the *gold*, and unite with the fulphur.

The fifth character of *gold* is, that it readily and fpontaneoufly, as by fome magnetic virtue, ftreaths and abforbs mercury: though what lord Bacon writes, viz. that *gold*, in limboing mercury, increafes in fpecific gravity, we doubt, is but ill warranted. It is more than probable it muft be increafed in bulk, more than in weight, and confequently muft be fpecifically lighter.

It may be added, that as foon as the mercury enters the *gold*, the metal becomes foft, like a paſte. See AMALGAMATION *of gold*, and GILDING.

The fixth character is, that it withſtands the violence both of lead and antimony, i. e. being fufed in the copel along with either of thofe matters, it does not diſſipate and fly off with them in fume, but remains fixed and unchanged.

All other metals, except *gold* and filver, melted with lead, periſh with it, and evaporate by fire; and in antimony, all other metals, except *gold*, even filver itſelf, undergo the fame fate. Thus, if a maſs conſiſting of *gold*, filver, ſtones, copper, &c. be fufed together with antimony, the feveral matters become ſeparated, and all but the *gold* riſes to the ſurface in form of a ſcoria, and is blown off with bellows; but the *gold* remains behind, much purified, as having loſt all its heterogeneous parts along with the other metals. And hence antimony is uſed as the teſt of *gold*. See REFINING.

The ſeventh character is that of all bodies it is the ſimpleſt (the primary elements being here excepted). By ſimple we here mean that whole minuteſt part has all the phyſical properties of the whole maſs. Thus, if a grain of *gold* be diſſolved in aqua regia, and a ſingle drop of the ſolution be taken, a quantity of *gold* may be ſeparated therefrom, which ſhall only be the millionth part of the grain, and yet ſhall have all the characters of *gold*. Or if you fuſe a grain of *gold* with a large maſs of ſilver, and mix the two together, ſo that the *gold* becomes equally diffuſed through the whole maſs, you will have in every particle of the maſs a particle of perfect *gold*. Accordingly, diſſolve any part of this mixture in aqua fortis, and a quantity of *gold* will precipitate to the bottom, bearing the ſame proportion, as ſome have ſuppoſed, to the grain that the part diſſolved did to the whole maſs. On which principle depends the art of ASSAYING.

But this does not appear to be ſtrictly true: for, in many caſes, there is a ſenſible inequality in the diſtribution of the *gold*. M. Hellot melted upwards of twenty pounds of ſilver, containing about a fifty-fixth part of *gold*, in a crucible, and poured it into cold water, in order to reduce it into grains; and by dipping at different times an iron ladle into the water, under the ſtream of metal, he received a part of the firſt running, a part of the middle and a part of the laſt; the three parcels, aſſayed ſeparately, were all found to differ with regard to the quantity of *gold* contained in them.

GOLD, *hiſtory of*. All the known parts of the earth afford this precious metal; though with great difference, in point of purity and abundance. Europe, ſo fertile in other reſpects, comes ſhort of all other quarters in *gold*. The moſt conſiderable mines in this quarter of the globe are thoſe of the Upper Hungary; and particularly that of Chremnitz, which has continued to yield *gold* for ten centuries. America furniſhes the moſt; and particularly the mines of Peru, Mexico, and Chili, and other provinces of the Spaniſh Weſt Indies; to which may be added the Braſils, belonging to the king of Portugal.

In many parts of Aſia, particularly Sumatra, Pegu, China and Japan, the Philippine iſlands, and Borneo, *gold* is found in conſiderable quantities. At Canton, the *gold* is caſt into ſhoes of about ten tale weight, or twelve ounces two penny-weights four grains, of an equal fineneſs: theſe ſhoes are bigger at both their ends than in the middle, formed with their brims riſing above the reſt; ſo that the upper ſide ſomewhat reſembles a boat; from the middle, which, in cooling, ſinks into a ſmall pit, ariſe circles one within another; and the ſmaller and cloſer theſe are, the finer the *gold* is. *Gold* in bars or ingots comes chiefly from Cochinchina and Tonquin: the ſhoes and bars are very often debaſed and gilt. By the laws of China, *gold* is forbidden to be exported.

The coaſt and interior parts of Africa likewiſe afford great quantities of this precious metal. Some *gold* has been diſcovered in Britain, at different times, though hitherto in ſmall quantities. It is chiefly found in that kind of tin-ore called the ſtream tin.

Glauber, an eminent chemiſt, aſſerts, that there is not any ſand or ſtone, but *gold* may be procured from, limeſtone only excepted: the miſfortune is, that the expence of ſeparating it much ſurmounts the profits.

Many of the common ſands, particularly the yellow, red, black, and thoſe inclining to a violet colour, appear to be rich in *gold*. Becher and Cramer preſume, that there is no ſand in nature entirely free from it; Becher undertook to ſeparate it with profit from the common ſea-ſands, and entered into engagement with the ſtates of Holland for eſtabliſhing a mineral work on this foundation: but the iſſue, though favourable, does not appear to have been ſufficiently lucrative; for the ſcheme was never proſecuted.

Gold is chiefly found in mines; though there is ſome alſo found in the ſand and mud of rivers and torrents; particularly in Guinea. This laſt is in form of a fine duſt, and is called *guanyoens, gold duſt*. From Cape-coaſt, on the coaſt of Guinea, we receive yearly between two and three thouſand ounces of the duſt; and three or four hundred ounces are ſaid to be collected yearly from the ſands of the Gambia, and caſt into bars at James-fort, one of our ſettlements on that river. The *gold* duſt from Africa, in its pureſt ſtate, is ſaid to be from twenty-one to upwards of twenty-two carats fine; but the natives frequently mix with it ſilings of braſs. However, this adulteration may be eaſily detected by the hydroſtatic balance, or by pouring on the mixture a ſmall quantity of aqua fortis, which will receive a blue tincture from the copper in the braſs.

There are many European rivers, which roll particles of *gold* in their ſand; from collecting which the neighbouring inhabitants derive ſome advantage: ſuch are the Rhine, the Rhone, the Garonne, the Danube, the Elb, &c. and the Schwartz, in Upper Saxony, is ſaid to be rich in this metal, and its ſands to be worked with great profit. The *gold* is found moſt plentifully in theſe rivers, where their courſe is ſlow and uninterrupted, where the ſand is reddiſh or blackiſh, which, being more ponderous than the white ſand, determines the particles of *gold* to ſubſide with it, and when the water has ſubſided after a flood.

Glauber tells us, that there is a third ſort of *gold*, ſcarce found any where but in the drains of the mountains of Chili, which they ſeparate from the earth by waſhing; whence the places where it is found, or ſeparated, are called *lavaderos*.

This earth is uſually reddiſh, and very fine: at about ſix feet deep it is mixed with grains of large duſt, and from hence commences the ſtratum, or bed of *gold*. Between are banks of ſoft bluiſh ſtone, mixed with yellow threads, which yet are not *gold*, but only pyrites, or marcaſite of *gold*.

When they have diſcovered any of this earth, they endeavour to bring rivulets to it (which in theſe mountains are very frequent) in order, by force thereof, to tear off the upper earth, and lay the golden ſtratum bare. This they forward by looſening it, and digging with ſpades, &c. As ſoon as the golden earth is uncovered, they turn off the water, and dig up the ſoil by force of arm; and loading it on mules, carry it to the lavaderos, i. e. a ſort of baſons of water, where the earth undergoing divers repeated lotions, in different waters, the earthy and impure part is all ſeparated and carried off by the ſtream, and the *gold* left at bottom. This method of getting *gold* is immenſely gainful; the expences being but trifling, compared with thoſe accruing in the common way by machines, fire, and quickſilver: the richeſt of theſe lavaderos is that de l'Eſtanois del Rey, twelve leagues from the Conception, a port of the South Sea. Thuringia, and ſome other places along the Rhine, are the only places in Europe where *gold* is got in this manner.

The way of ſeparating it is this: they have a trough made with a declivity, and lined at the bottom with flannel, or coarſe cloth; the ſand is received into this; and while it is ſtirred about in the water by the hand, the ſand is waſhed off, and the ſmall particles of *gold* left in the pores, and among the woolly matter of the flannel, which is afterwards waſhed out from thence. The *gold* is afterwards extracted from the remaining matter by mercury.

This is the method where the ſand is fine; but when it is mixed with large gravel, they ſift it through wire ſieves, whoſe meſhes are of one determinate ſize, or a kind of baſket made of rods, placed at the upper end of the trough, by which means all the *gold* is ſure to go through with the ſand, and the gravel or larger ſtones are left behind, and thrown away. The ſand thus ſeparated is treated as before; and there is no danger of any *gold* being

being thrown away with the gravel, becauſe it is extremely rare to meet with any one grain of *gold* in this ſtate ſo large as a barley-corn; and therefore as the meſhes of their ſieves are kept to more than that ſize there is no fear of loſing any of the metal.

The *gold* of mines is of two kinds; the one in ſmall pieces, or grains, of different forms and weights. Of this ſort, among the ſpecimens ſent by Columbus into Spain, to let them ſee the richneſs of his diſcovery, there were ſome of eighteen ounces weight; and the relations of thoſe days aſſure us, that in 1502 there were others found of thirty-two pounds weight.

Reaumur reports, that a piece was ſhewn to the French academy, which weighed four hundred and forty-eight ounces; and another, in the cabinet of Antonio Portocarero, weighed upwards of five hundred and twenty-eight ounces; both which pieces, on being aſſayed, were found to be of different fineneſs in different parts of the maſs. However, it is rare to meet with maſſes of the weight even of an ounce: the largeſt in the Britiſh Muſeum weighs but fifteen penny-weights.

The other kind of *gold* is dug up in the ſtony glebes, which are what they call the *mineral ore of gold*: theſe glebes are of various colours, and lie uſually one hundred and fifty, or one hundred and ſixty fathom deep. They ſtrike fire with ſteel, and are not ſoluble in aqua fortis. Along with the *gold* they uſually contain ſome other mineral and metallic matter, particularly ſilver; without ſome ſhare of which it is ſcarce ever found.

The quantity of *gold*, in proportion to the earthy and ſtony matter mixed with it, appears to be in general exceeding ſmall. Voyagers of credit relate, that the common yield is no more than five or ſix ounces of *gold* upon the caſon, or fifty hundred pounds of the mineral.

GOLD, *manner of ſeparating*. They firſt break the metalline ſtone with iron mallets, pretty ſmall; then carry it to the mills, where it is ground into a very fine powder; and laſtly paſs it through ſeveral braſs-wire ſieves one after another, the laſt as fine as any of our ſilk ſieves.

The powder thus prepared is laid in wooden troughs, and ſoaked for ſome time in a ſolution of common ſalt; the proper quantity of mercury is then ſqueezed in through a linen cloth, ſo as to fall like a dew over the ſurface; and the mixture being well ſtirred and kneaded, the *gold* is incorporated, with the application of a gentle heat, in five or ſix days. After this the water, with the recrementitious earth, is driven out of the tubs by means of other hot waters poured thereon. This done, there remains nothing but a maſs of mercury with all the *gold* that was in the ore. The mercury they ſeparate from it by diſtillation in large alembics. The *gold*, in this ſtate, is called *virgin gold*; as well as that found in the ſand of rivers, or that in grains in the mines, becauſe none of them have paſſed the fire. After this they uſually fuſe it in crucibles, and caſt it into plates, or ingots.

The method of working this ore at Chremnitz in Hungary, does not differ much from that already deſcribed, and it is as follows: they waſh the pounded ore very often, and lay it in powder upon cloths, and by the gentle and obtique deſcent of the water over it, and their continual ſtirring of it, the earthy, clayiſh, and lighter parts are all clean waſhed away, while the heavier and metalline remain in the cloth. Not much unlike to this proceeding is that with ſheep's ſkins and wool, which they place either in the water that comes from the works, or in the ſtreams of rivulets, which have their origin in hills where there is much gold; ſo that while the water or fluid parts paſs through or over them, the more ſolid, heavy, and metalline are infnared and detained, and by this means the ſkin becomes a golden-fleece. The cloths which are by the Chremnitz-works in this manner impregnated with *gold*, are waſhed in large tubs of water, and after ſettling the water is decanted ſlowly off; the ſediment which is left behind is, after this, waſhed in three or four other waters, and to the clean remainder they add quickſilver, which they then work and knead into an amalgam, like dough or paſte. When they have worked this together for an hour or two, they throw it into water, and waſh off the quickſilver, which did not adhere, and then there remains a pure and perfect maſs of the amalgam. They ſqueeze as much of the quickſilver as they can from this, firſt though coarſe cloths and then through fine ones; they then put the remainder on a perforated plate, which they place over a deep pan, ſet in the earth, in the bottom of which there is put ſome quickſilver; they then cover with a hollow earthen-lid, luting it carefully on, and when the lute is dry they make a charcoal fire over it. By this means the quickſilver yet remaining with the *gold* in the amalgam, is driven off, and runs down through the holes of the plate, mixing itſelf with the reſt in the bottom of the pan, and the *gold* is left alone in a ſpungy maſs, which only needs once melting in the common way to be pure and malleable *gold*. Brown's Travels, p. 67. See other proceſſes deſcribed under the article AMALGAMATION *of gold*.

When the *gold* is intimately combined in the compoſition of ferruginous ſands, the ſand ſhould be made red hot, and quenched in water, and the ignition and extinction repeated four times or oftener. Mix the ſand, thus calcined, with twice its weight of granulated lead, and its own weight of black flux, conſiſting of one part of nitre, and two or three of tartar, mixed and burnt in a covered veſſel to a black alkaline coal, and then put the mixture into a crucible, and cover it with ſea-ſalt dried over the fire till it has ceaſed to crackle. Expoſe the crucible in a blaſt-furnace to a ſtrong fire, and ſtir the matter occaſionally with an iron rod; when the ſcoria is become thin as water, which is known by the rod's coming out almoſt clean, let the crucible be left to cool; and the *gold* contained in the ſand will be tranſferred to the lead, and may be ſeparated from it with a cupel or teſt. The ſilver contained in theſe ſands, may be ſeparated from the *gold*, after cupellation, either by aqua regia or aqua fortis. Inſtead of the black flux, four parts of pot-aſh, and three of powdered charcoal, will anſwer the purpoſe when applied to thirty-two parts of lead, and fifteen of the calcined ſand. Or, the calcined ſand may be boiled in melted lead, without any inflammable or ſaline addition. When *gold* is intimately combined with other metals in their ores, the ore is to be run down in the ſame manner as the ſame kind of ore without *gold*: and the *gold* may be afterwards ſeparated by different proceſſes according to the nature of the metal.

There are various methods of ſeparating *gold* from gilt works: it may be ſeparated from the ſurface of ſilver, either by ſpreading over the gilt ſilver a paſte made of powdered ſal ammoniac moiſtened with aqua fortis, and heating it till the matter ſmokes, and is nearly dry; throw it into water, and the *gold* will eaſily come off by rubbing it with a ſcratch bruſh; or, by putting the gilt ſilver into common aqua regia, nearly boiling and turning the metal frequently, till it becomes all over black; then waſh it with water and rub it with the ſcratch bruſh, which will diſengage the *gold* left by the aqua regia. See GILDING.

Gold may be ſeparated from gilt copper, by applying a ſolution of borax to the gilt parts with a pencil, and ſprinkling over the place thus moiſtened, a little powdered ſulphur; when the piece is made red-hot, and quenched in water, the *gold* may be wiped off with a bruſh.

Gold may be recovered from wood, gilt on a water ſize, by ſtooping it for a quarter of an hour, in a quantity of very hot water, ſufficient to cover it; then ſcrub the wood in a little warm water, with ſhort ſtiff briſtle bruſhes of different ſizes: boil the whole mixture of water, ſize, *gold*, &c. to dryneſs; make the dry matter red hot in a crucible to burn off the ſize, and grind the remainder with mercury. The *gold* will be more eaſily laid hold of by the mercury, by the addition of ſome clean ſand.

GOLD, *manner of aſſaying*. This is performed with the TOUCH-*ſtone*, and TOUCH-*needles*, but more ſecurely by fire; which latter method conſiſts of two proceſſes; the one for ſeparating *gold* from ſilver by aqua fortis, and the other from baſe metals, by keeping the mixt infuſion for ſome time upon a cupel or COPPEL, with the addition of lead. See ASSAYING.

GOLD, *manner of refining*. There are three principal methods of refining *gold*; the firſt with antimony; the ſecond with ſublimate; and the third with aqua fortis. This laſt method is called *departing*, or *parting*. See DEPART, PARTING, and QUARTATION.

For the two former, ſee REFINING.

There are ſeveral other methods of refining *gold*, with aqua regia, with the vitriolic acid, with lead and aſhes called cupellation, COPPELLING, or teſting, with a compoſition of nitre, or ſea-ſalt, green vitriol calcined, and brick-duſt, called *cementation*, which the reader will find deſcribed under the articles ASSAYING, CEMENTATION, PARTING, REFINING, and TESTING.

GOLD, *for the making of*. See PHILOSOPHER'S *ſtone*, and TRANSMUTATION.

GOLD *beating*, and GOLD *beater's ſkin*. See GOLD *leaf*.

GOLD, *burniſhed*, is that which is poliſhed with a ſteel inſtrument called a BURNISHER, if it be wrought *gold*, or gilding on metal; or with a wolf's tooth, if it be gilding in water. See GILDING.

GOLD *chain*. See CHAIN.

GOLD *coin*, or *ſpecies of gold*. See COIN and COINAGE.

Anderſon, in his Hiſtory of Commerce, vol. i. p. 174, dates the firſt coining of *gold* in England in the year 1344; for it appears by 18 Edw. III. cap. 16. that three different coins of *gold* were then ordered to be coined; viz. one of the value of ſix ſhillings, being the weight of two ſmall florins of Florence; a ſecond of half that

value and weight; and a third of a quarter of the firſt. The *gold* was 23 carats 3½ grains fine, with half a grain of alloy. Three other *gold* coins were alſo coined in the ſame year; viz. one of 6*s.* 8*d.* value, called a *gold* noble; others of half that value, called *marks* nobles, and a third a quarter of the firſt, called *farthing*, or farthing noble. For an inſtrument invented by Mr. Boyle for detecting counterfeit *gold* coin, ſee *Floating* LOADSTONE.

GOLD *colour on glaſs and china*. See GLASS, GILDING, and PORCELAIN.

GOLD-*coloured glazing*. See GLAZING.

GOLD-*coloured metal* is produced by melting zinc with copper. According to the purity of the zinc and copper, the proportions in which they are mixed, and the intimacy of their union, the compound metal proves more or leſs malleable, and approaches more or leſs to the colour of *gold*. Some direct the zinc to be taken only in a fifth or ſixth part of the weight of the copper, and others in an equal weight or more. Dr. Lewis obſerves, from the reſult of many experiments, that both with the ſmalleſt and largeſt of theſe quantities of zinc, the metal proves more like *gold* than with the intermediate proportions.

The colour of theſe compounds is improved by a ſmall mixture of ſome other metallic bodies. Cramer recommends the addition of a ſmall quantity of pure tin to copper, melted with a fourth or ſixth part of zinc, which forms a compound metal, that acquires, on being well cleaned, and laid in the air for ſome days, a ſuperficial colour of fine *gold*. Geoffroy ſays that iron has the beſt effect; with the proportions of ten parts of zinc, eight of copper, and one of iron-filings, he produced a metal of a fine ſmooth grain, compact, hard, and bright, and of a beautiful *gold* colour. By making the copper firſt into braſs, and then melting it with a ſuitable quantity of zinc, a metal may be obtained of ſuperior quality to that produced either by melting the copper and zinc, or by impregnating the copper with zinc, by cementation and fuſion with calamine; which is a method ſometimes practiſed. A very ingenious artiſt, ſays Dr. Lewis, who now prepares a *gold*-coloured metal in great perfection, has a fine kind of braſs made on purpoſe for this uſe. The union of the copper and zinc in fuſion, ſucceeds beſt and with leaſt loſs of the zinc, according to Dr. Lewis, by uſing a mixture of black flux and borax, or a compoſition of twelve parts of green glaſs powdered, ſix parts of potaſh, two of borax, and one of powdered charcoal: when this flux is fuſed in the crucible, the copper and zinc are dropped into it, and when they appear perfectly melted, they are to be well ſtirred together with an iron rod, and expeditiouſly poured out. The ſame flux will ſerve for melting ſeveral freſh quantities of the metal. Dr. Hooke gives the following receipt for making a *gold*-coloured metal: eight parts of diſtilled *verdigriſe*, i. e. of verdigriſe purified by ſolution in diſtilled vinegar and cryſtallization, and four parts of Alexandrian tutty, with two of nitre, and one of borax, are directed to be mixed with oil to the conſiſtence of pap; then melted in a crucible, and poured into a flat mould firſt well warmed. A compoſition of this kind is called AURUM *ſophiſticum*.

The following method is recommended by Homberg for giving a *gold* colour to copper, without the addition of zinc; making an amalgam of one part pure copper, and three parts quickſilver; ſee AMALGAMATION *of copper*: boil this in ſtrong water for two hours, then diſtil off the quickſilver in a retort, and cohobate it once; take out the copper and fuſe it, and it will be found of a beautiful *gold* colour, more ductile than common copper, and extremely well fitted for watch-work, gilding and the finer machines and utenſils. The celebrated Mr. Pott affirms, that a *gold*-coloured metal may be made from a mixture of copper and tin, and directs it to be compounded in the following manner: take one half ounce of tin aſhes, and four half ounces of copper; melt them well together in a cloſe luted crucible, with a ſtrong fire: or, take one half ounce of the pureſt tin cut in pieces, and ſixteen half ounces of pure copper beaten into thin plates; lay the tin between the copper-plates, lute the crucible cloſe, and melt with a ſtrong fire. See *Prince's* METAL and TOMPAC.

Silver is tarniſhed ſuperficially, by certain vapours, as that of putrified urine, to a colour ſo like that of *gold*, that ſeveral edicts have been iſſued in France to prevent frauds of this kind with regard to wire and laces.

GOLD-*coloured pigments*. See PIGMENTS.

GOLD-*coloured varniſh*. See LACQUER.

GOLD, *Crown*. See STANDARD.

GOLD, *Dutch*, is a kind of leaf uſed in GILDING, *&c.* which is copper gilt, or braſs beaten into leaves like the genuine GOLD *leaf*.

GOLD, *farthing of*. See FARTHING.

GOLD, *fine* or *pure*, is that purged by the fire of all its impurities, and all alloy. The Latins call it *aurum purum, aurum primum, aurum obrizum, aurum collum*.

The moderns frequently call it *gold of twenty-four carats*; but, in reality, there is no ſuch thing as *gold* ſo very pure; and there is always wanting at leaſt a quarter of a carat. *Gold of twenty-two carats* has one part of ſilver, and another of copper: that of twenty three carats has half a part, i. e. half a twenty-fourth of each.

Boutereuc maintains, that the electrum of the ancients was *gold* of nineteen carats; or four parts *gold*, and a fifth ſilver.

From an ordinance of king John of France, it appears that the *gold* then ſtruck at Paris was of 19 carats 1-5th; and yet it is added that it was the beſt and fineſt *gold* then known on earth. See STANDARD.

GOLD, *fulminating, aurum fulminans*. See AURUM and *Chemical Hiſtory of* GOLD, above.

GOLD, *leaf*, or *beaten* GOLD, is *gold* beaten with a hammer into exceedingly thin leaves. It is aſtoniſhing to conſider the ſmeneſs to which a body of *gold* is thus reduced. In an experiment of Reaumur's, forty-two ſquare inches and three tenths of *gold* leaf, weighed one grain troy; and Mr. Boyle found that fifty and ſeven tenths weighed but a grain. As a cubic inch of *gold* weighs 4608 grains, the thickneſs of the *gold* leaf examined by the one was the 207360th, and of that by the other only the 248832nd part of an inch. See DUCTILITY of *Gold*.

This *gold* is beat on a ſmooth block of black marble, from two hundred to ſix hundred pounds in weight, and about nine inches ſquare on the upper ſurface, fitted into the middle of a wooden frame, about two feet ſquare, ſo as that the ſurface of the marble and frame form one even plane. Three of the ſides are furniſhed with a high ledge, and the front, which is open, has a leather flap faſtened to it, which the *gold* beater uſes as an apron, for preſerving the fragments of *gold* that fall off. Three hammers are employed in this buſineſs, having two round and ſomewhat convex faces; the firſt, called the *catch* hammer, is about four inches in diameter, and weighs fifteen or ſixteen pounds: the ſecond, called the *ſhodering* hammer, weighs about twelve pounds, and is about the ſame diameter: the third, called the *gold* hammer, or *finiſhing* hammer, weighs ten or eleven pounds, and is nearly of the ſame width. The French uſe four hammers, differing both in ſize and ſhape from thoſe of our workmen.

The *gold beaters* alſo uſe three kinds of animal membranes; ſome of which are laid between the leaves to prevent their uniting together, and others over them to defend them from injury by the action of the hammer. For the outſide cover, they uſe common parchment made of ſheep ſkin; for interlaying with the *gold*, firſt, the ſmoothеſt and cloſeſt vellum made of calves ſkin; and afterwards, the much finer ſkins of ox-gut, ſtript off from the large ſtraight gut ſlit open, prepared on purpoſe for this uſe, and hence called *gold beater's ſkin*. The general proceſs of their preparation, is ſaid to conſiſt in applying one upon another, by the ſmooth ſides, in a moiſt plate, to which they readily cohere and unite inſeparably, ſtretching them on a frame, and carefully ſcraping off the fat and rough matter, ſo as to leave only the fine exterior membrane of the gut; beating them between double leaves of paper, to force out the remaining moiſture; moiſtening them once or twice with an infuſion of warm ſpices, and laſtly, drying and ſmoothing them. It is ſaid, that ſome calcined gypſum, or plaiſter of Paris, is rubbed with a bare foot, both on the vellum and ox-gut ſkins, which fill up their pores, and prevent the *gold* leaf from ſticking. Theſe ſkins, after ſeventy or eighty repetitions, become unfit for uſe; but their virtue may be reſtored by interlaying them with leaves of paper moiſtened with vinegar or white wine, beating them for a whole day, and afterwards rubbing them over with plaiſter of Paris: and even holes of them may be repaired by the dexterous application of freſh ſkins.

GOLD, *the manner of preparing and beating*. They firſt melt a quantity of the pureſt *gold* in a blackлead crucible, with ſome borax, in a wind furnace, and pour it into an iron ingot mould, ſix or eight inches long, and ¾ of an inch wide, previouſly greaſed and heated: the bar of *gold* is made red hot and forged on an anvil into a long plate, which is farther extended, by being paſſed repeatedly between poliſhed ſteel rollers, till it becomes a ribbon, as thin as paper. This ribbon is divided by compaſſes, and cut with ſhears into equal pieces, which are forged on an anvil till they are an inch ſquare, and afterwards well nealed. Two ounces of *gold*, which is the quantity melted at a time, make a hundred and fifty of theſe ſquares, ſo that each of them weighs ſix grains and two fifths; and as 4608 grains of *gold* make a cubic inch, the thickneſs of the ſquare pieces is about the 760th part of an inch.

inch. All these squares are interlaid with leaves of vellum, three or four inches square; one leaf being laid between every two of them, and about twenty more of the leaves are laid on the outsides: over these is drawn a parchment case, open at both ends, and over this another, in a contrary direction, so that the vellum and *gold* leaves are kept tight and close. The whole is then beaten with the heaviest hammer, till the *gold* is stretched to the extent of the vellum: the pieces, taken out of this case or MOULD, are cut in four with a steel knife; and the six hundred pieces thus produced are interlaid, in the same manner, with pieces of the ox-gut skins, five inches square. The beating is repeated with a lighter hammer, till the golden plates have acquired the extent of the skins, when they are divided into four, by a piece of cane cut to an edge. The whole number of leaves is then divided into four parcels, which are interlaid, as before, and beaten separately, till they are stretched for the third time to the size of the skins. The French repeat the division and beating once more. After the last beating, the leaves are taken up by the end of a cane instrument, and being thrown flat on a leathern cushion, are cut to a size, one by one, with a square frame of cane made of a proper sharpness, or with a frame of wood edged with cane. They are then fitted into books of twenty-five leaves each, the paper of which is well smoothed, and rubbed with red bole to prevent their sticking to it. The size of the French *gold* leaves is from somewhat less than three inches to 3¼ square; that of ours, from three inches to 3¼.

The French prepare what they call green *gold* leaf, from a composition of one part of copper and two of silver, with eighty of *gold*; but Dr. Lewis observes that such an admixture gives no greenness to *gold*, and that this kind of leaf is made from the same fine *gold*, as the highest *gold*-coloured sort, the greenish hue being a superficial tint given to the *gold* in some part of the process: this leaf is chiefly used for the gilding of books. A kind of leaf, called *party gold*, is formed by laying a thick leaf of silver, and a thinner one of *gold*, flat on one another; they are then heated and pressed together, so as to unite and cohere: and being beaten into fine leaves, as in the foregoing process, the *gold*, though only in quantity a fourth of that of the silver, extends over it and every where covers it.

GOLD, *million of*, a phrase often used to signify a million of crowns.

GOLD *money*. See MONEY and COIN.

GOLD, *Mosaic*, or *gold* applied in pannels on a proper ground, distributed into squares, lozenges, and other compartments; part of which is shadowed to raise or heighten the effect. See MOSAIC.

GOLD *plates for enamelling* are generally made of ducat *gold*, whose fineness is from 23¼ to 23¾ carats; and the finest *gold* is the best for this purpose, unless where some parts of the *gold* are left bare and unpolished, as in watch-cases, snuff-boxes, &c. for which purpose a mixture of alloy is necessary, and silver is preferred to copper, because the latter disposes the plates to tarnish, and turn green. See ENAMELLING.

GOLD, *potable*, *aurum potabile*. See AURUM *potabile*, and the *Chemical history of* GOLD.

GOLD *powder*, for the purposes of GILDING, may be made by grinding *gold* leaf with honey; see *Shell*-GOLD: by distilling to dryness a solution of *gold* in aqua regia; by evaporating the mercury from an amalgam of *gold*, taking care well to stir the mass near the end of the process; or by precipitating *gold* from its solution in aqua regia; by applying it to a solution of common green vitriol in water, or some copper, &c. See *Chemical history of* GOLD.

GOLD *precipitate with tin*, called also, from its supposed discoverer, *cassius*, is prepared with great care both in dissolving the tin, and diluting the solution. For this purpose, a mixture of two parts of aqua fortis, and one of spirit of salt, is supposed to be the best menstruum for the tin. Into this mixture some fine block tin, granulated, is to be let fall, grain by grain, waiting till one grain is dissolved before another is dropped in, that the dissolution may go on slowly, without any heat or discharge of fumes. The *gold* is dissolved in common aqua regia; and a few drops of this solution being mixed with some ounces of pure water, as many drops of the solution of tin are added. If the mixture changes immediately to a clear bright purplish red colour, the due degree of dilution has been determined; if the colour appears dull, a greater quantity of water must be added for the rest of the solutions. After the mixture has deposited its red matter, and become clear, a little more of the tin solution is to be dropped in, for discovering and precipitating any *gold* that may still remain in it: the liquor being then poured off, the precipitate is washed and dried. Lewis's Com. Phil. Techn. p. 176. See *Ruby* GLASS.

For other methods of precipitating *gold*, see *Chemical history of* GOLD.

GOLD, *quern*. See QUERN *gold*.

GOLD, *size*, is that used by the gilders and illuminers, and with which *gold* letters are written. It is made by grinding *gold* leaves, or *gold* beaters fragments, with a little honey, and afterwards separating the honey from the powdered *gold* by means of water. When the honey is washed away, the *gold* may be put on paper, or kept in shells; whence its name. When it is used, it is diluted with gum-water, or sope-suds. The German GOLD-*powder*, prepared from the Dutch *gold* leaf in the same manner, is generally used, and, when it is well scoured with varnish, answers the end in *japanners* GILDING, as well as the genuine.

GOLD-*size* for burnished GILDING is prepared of one pound and a half of tobacco-pipe clay, half an ounce of red chalk, a quarter of an ounce of black lead, forty drops of sweet oil, and three drams of pure tallow: grind the clay, chalk, and black-lead, separately, very fine in water; then mix them together, add the oil and tallow and grind the mixture to a due consistence.

GOLD-*size of japanners* may be made by pulverizing gum animi and asphaltum, of each one ounce; red-lead, litharge of *gold*, and umber, of each one ounce and a half, mixing them with a pound of linseed oil, and boiling them, observing to stir them till the whole be incorporated, and appears, on growing cold, of the consistence of tar; strain the mixture through a flannel, and keep it, capped up in a bottle, for use. When it is used, it must be ground with as much vermilion, as will give it an opake body, and diluted with oil of turpentine, so that it may be worked freely with the pencil. A simple preparation consists of one pound of linseed oil, and four ounces of gum animi; powder the gum, and mix it gradually with the boiling oil: let it continue to boil, till it becomes of the consistence of tar; strain it through a coarse cloth, keep and use it as the other.

GOLD-*smith*, or as some chuse to express it, *silver-smith*, the artist who makes vessels, utensils and ornaments in *gold* or silver. The *goldsmiths* work is either performed in the mould, or beat out with the hammer or other engine. All works that have raised figures are cast in moulds, and afterwards polished and finished; plates or dishes of silver or *gold* are beat out from thin flat plates, and tankards and other vessels of that kind are formed of plates soldered together, and their mouldings are beat, not cast. The business of the *goldsmith* formerly required much more labour than it does at present, for they were obliged to hammer the metal from the ingot to the thinness they wanted: but there are now invented flatting-mills, which reduce metal to the thinness that is required, at a very small expence. The *goldsmith* is to make his own moulds, and for that reason ought to be a good designer, and have a taste in sculpture: he also ought to know enough of metallurgy to be able to allay mixed metals, and to mix the alloy.

The *goldsmith* in London employs several hands under him, for the various articles of his trade. In this great city there are always hands that excel in every particular branch of the trade, and there is commonly employment enough for every one in his particular branch. The jeweller, the snuff-box and toy-maker, the silver-turner, the gilder, the burnisher, the chaser, the refiner, and the *gold*-beater, are all employed by and under the *goldsmith*.

GOLD-*smiths, Company of, in London*. See COMPANY.

GOLD *thread*, or *spun gold*, is a flatted gilt wire, wrapped or laid over a thread of yellow silk, by twisting it with a wheel and iron bobins. By means of a curious but complex machinery, a number of threads is thus twisted at once by the turning of one wheel. The principal art consists in so regulating the motion, that the several circumvolutions of the flatted wire on each thread may just touch one another, and form, as it were, one continued covering. At Milan, it is said, they make a sort of flatted wire, gilt only on one side, which is wound upon the thread, so that only the gilt side appears. There is also a gilt copper wire, made in the same manner as the gilt silver, chiefly at Nuremberg: and the ordinance of France requires it to be spun on flaxen or hempen thread. The Chinese, instead of flatted gilt wire, use slips of gilt paper, which they interweave in their stuffs and twill upon silk threads.

GOLD, *ton of*, is a kind of money of account, used by the Dutch, and in some other countries, containing a hundred thousand florins.

A hundred pounds of, or in, *gold*, is found to weigh two pounds ten ounces: the sum in silver weighs twenty-

six

six pounds four ounces. Twenty-two pence, in copper farthings and halfpence, weigh one pound avoirdupois. A tun of *gold*, at 4*l.* the ounce, amounts to 896000*l.* A tun of silver, at 5*s.* 2*d.* the ounce, to 6200*l.* A pound sterling of *gold*, to 48*l.* An ounce is worth 4*l.* The penny-weight 4*s.* One grain 2*d.* A pound of sterling silver amounts to 3*l.* 2*s.* An ounce is worth 5*s.* 2*d.* The penny-weight 3*d.* and something more; one grain a half-penny. A pound of silver avoirdupois comes to 3*l.* 5*s.* 3*d.* halfpenny.

GOLD, *virgin*, is pure *gold*, just as it is taken out of the mines, before it has undergone any action or preparation of fire; whence the Greeks call it ἄπυρος.

Such is the *auxyferous*, or *gold-duft*, and that got by lotion in the lavaderos in Chili: it is added, that there are maffes or lumps of pure *gold* found in the mines, particularly thofe of Hungary. Accordingly, in the emperor's collection, are ftill preferved feveral plates of *gold* faid to have been thus found.

Virgin *gold* is fometimes very pale, and fo foft that it may be moulded into any figure with the hand; it even takes an impreffion from a teal, like the fofteft wax. To harden it, as alfo to heighten its colour, they mix emery with it.

GOLD, *white*. See PLATINA.

GOLD *wire* is a cylindrical ingot of filver, above an inch thick, two feet in length, and weighing about twenty pounds, fuperficially gilt, or covered with *gold*, at the fire, and afterwards drawn fucceffively through a great number of little round holes of a wire-drawing iron, each lefs than the other, till it be fometimes no bigger than a hair of the head. There is very little wire made entirely of *gold*, and this chiefly for one particular purpofe, that of filigree work.

It is amazing to what degree of finenefs the *gold* is here drawn; and yet it ftill keeps firm together, and never fhews the leaft ftgns of the filver underneath it. The reader may fee a computation hereof, as alfo a more particular account of the manner of proceeding, under the article DUCTILITY *of gold*.

GOLD *wire flatted*, is the former wire flatted between two rollers of polifhed ftecl, to fit it to be fpun in filk, or to be ufed flat as it is, *without* fpinning, *in certain* ftuffs, laces, embroideries, &c.

Manner of forming GOLD *wire and* GOLD *thread, both round and flat.* The firft object, which is of the utmoft confequence, is the choice of the pureft *gold*; for on this chiefly depends the beauty and durability of the colour of the laces, brocades, and other commodities prepared from it. To a difference in this refpect, the boaftcd fuperiority of the French laces to the generality of thofe made in England, till of late, has been wholly owing. With regard to the filver that forms the body of the wire, it is faid that there is an advantage in its being alloyed. The French filver for gilding is faid to be alloyed with five or fix penny-weight, and ours with twelve penny weight of copper, in the pound troy. The *gold* is employed in thick leaves, which are applied all over the filver rod, and preffed down fmooth with a ftecl burnifher. Several of thefe leaves are laid over one another, as the gilding is required to be more or lefs thick. The fmalleft proportion allowed by act of parliament, is 100 grains of *gold* to a pound, or 5760 grains of filver. The largeft proportion for the beft double gilt wire was formerly 120 grains to a pound; but the proportion of *gold* has been of late increafed. The firft part of the drawing procefs, as well as the preparation and gilding of the filver rod, is performed by the refiner, who ufes plates of hardened ftecl, with a piece of tough iron welded on the back to prevent the ftecl from breaking. The holes in thefe plates are conical, being larger in the back part than in the ftecl, that the rod may not be fcratched againft the outer edge, and that they may contain beeswax, which makes the rod pafs more freely, and preferves the *gold* from being rubbed off. One end of the rod, made fmaller than the reft, is puthed through a hole that will admit it, when the plate has been properly fecured, and laid hold of by ftrong pincers, called clamps, adapted to the purpofe; to thefe pincers which are fo contrived, that the force, which pulls them horizontally, ferves at the fame time to prefs them together, a rope is faftened by one end, and the other end goes round a capftan with crofs bars, which requires the ftrength of feveral men to turn it. The rod, thus drawn through, is well nealed: it is then paffed through the next hole; and the nealing and drawing are repeated, till, being reduced to about the fize of a large quill, it is delivered in coils to the wire-drawers. The remainder of the procefs requires plates of a different quality, which are brought from Lyons in France, and are formed of a metallic maft, whofe prevailing ingredient is iron: the holes are drilled in them here. Thefe plates are of two ſorts; fome of conſiderable thickneſs, for the wire in its larger ſtate, and others about half as thick, for the finer wire. In the uſe of theſe plates, furniſhed with a variety of holes, the dexterity of the workman principally conſiſts in adapting the hole to the wire: for this purpoſe he uſes a braſs plate, called a ſize, on which is meaſured, by means of notches like ſteps cut at one end, the increaſe which a certain length of wire ſhould gain in paſſing through a freſh hole; and if the wire is found to ſtretch too much or too little, the hole is widened or contracted. Slits of different widths, in thick poliſhed iron rings, ſerve alſo as gages for meaſuring the degree of fineneſs of the wire.

The wire-drawer's proceſs begins with nealing the large wire received from the refiner, which he does, by plating it, coiled up, on ſome lighted charcoal, in a cylindrical cavity, called the pit, under a chimney, and throwing more burning charcoal over it. When it is cooled by being quenched in water, one end is paſſed through the firſt hole in the thick plate, and faſtened to an upright wooden cylinder ſix or eight inches in diameter; in the top of which are two ſtaples, and through theſe is paſſed the long arm of a handle, by which the cylinder is turned on its axis by ſeveral men. By this proceſs, called *dragging*, the wire is frequently nealed and quenched, after paſſing through every hole, or every other hole, till it is brought to about the ſize of the ſmall end of a tobacco-pipe; and then cut into portions for the fine wire-drawer. In this laſt part of the wire-drawing proceſs, nealing is not neceſſary; but the wire is waxed at every hole. The contrivance for drawing the wire through the plate in this caſe, when leſs force is neceſſary, is a kind of wooden wheel placed horizontally, leaving in its upper ſurface ſmall holes at different diſtances from the axis, into one or other of which, according to the force required, is inſerted the end of an upright handle, whoſe upper end is received in a hole made in a croſs bar above. From this the wire is wound off upon a ſmaller cylinder, called a rechett, placed on the ſpindle of a ſpinning-wheel; and this cylinder being placed behind the plate, the wire is again drawn through upon the firſt; and being brought to the proper fineneſs, it is nealed for the *flatting mill*. In this nealing, the wire is wound on a large hollow copper bobin, ſet upright, including ſmall-coal, and encompaſſed with lighted charcoal or ſmall-coal, communicating a gradual heat. The wire, in this ſtate, muſt be watched and removed from the heat, when it appears of the proper colour. The next operation is that of the flatting-mill, which conſiſts of two perfectly round and exquiſitely poliſhed rollers, formed internally of iron, and welded over with a plate of refined ſteel: theſe rollers are placed with their axis parallel, and their circumferences nearly in contact; they are both turned with one handle: the lowermoſt is about ten inches in diameter, the upper little more than two, and their width or thickneſs is about an inch and a quarter. Theſe rolls are ſometimes repoliſhed with putty, prepared by calcining a mixture of lead and tin. The wire, unwinding from a bobin, and paſſing between the leaves of a book gently preſſed, and through a narrow ſlit in an upright piece of wood, called a keech, is directed by a ſmall conical hole in a piece of iron, called a guide, to any particular part of the width of the rollers, ſome of the beſt of which are capable of receiving, by this contrivance, forty threads. When the wire is flatted between the rollers, it is wound again on a bobin, which is turned by a wheel, fixed on the axis of one of the rolls, and ſo proportioned, that the motion of the bobin juſt keeps pace with that of the rolls. See on the ſubject of the preceding articles, Dict. of Chemiſtry, Eng. edit. 1777, and particularly Dr. Lewis's Philoſophical Commerce of Arts paſſim.

GOLD, in *Medicine* and *Chemiſtry*. The Chemiſts make ſeveral preparations of *gold* for medicinal uſes; as ſalts, mercuries, and tinctures of *gold*; but it is a point not yet well agreed on, whether *gold* have any real property whereby it may be of uſe in medicine.

Some mechanical phyſicians have had a notion, that if the particles of *gold* could be rendered fine enough, ſo as to circulate with the blood, that it would prove more effectual in the cure of diſeaſes than mercury. But this is a mere hypotheſis. The *aurum fulminans* has been uſed, and other preparations of *gold* are to be met with in authors; but they ſeem to meet with little credit among modern practitioners.

GOLD, in *Heraldry*, is one of the METALS, more uſually called by the French name, OR.

GOLD-*finch*, in *Ornithology*, is the FRINGILLA *carduelis* of Linnæus. This bird is peculiarly beautiful in its colour, the elegance of its form, and the muſic of its notes. The bill is white, tipt with black, the baſe being ſurrounded with a ring of rich ſcarlet feathers; a black line

runs

tons from the corner of the mouth to the eyes; the cheeks are white; the top of the head is black: the hind part of the head is white; the back, rump, and breast, are of a fine pale tawny brown; the belly is white. the covert feathers of the wings, in the male, are black in the female, brown; the quill-feathers black, marked in their middle with a beautiful yellow, the tips white; the tail black, but most of the feathers are marked near their ends with a white spot; the legs are white. The black and yellow in the wings of the female are less brilliant than those of the male. The young bird, before it moults, is grey on the head, and called by the bird-catchers a *grey-pate*. There is another variety of *gold-finch*, which is scarce, and called a *chevoret*, from the manner in which it concludes its jerk: it is distinguished from the common sort by a white streak, or by two, and sometimes three white spots under the throat. The *gold-finch* is very docile, and its note is very sweet. In winter these birds feed on seeds, particularly those of the thistle. They are fond of orchards, and often build in an apple or pear-tree; their nest is elegantly formed of fine moss, liver-worts, &c. on the outside, and within lined with wool and hair. The *gold-finch* lays five white eggs, marked with deep purple spots on the upper end. Some have supposed this bird to be the *acanthis* of the ancients; but Pennant appropriates that appellation to the LINNET. Brit. Zool. vol. i. p. 332, &c.

GOLD *fish*, in *Ichthyology*, is the CYPRINUS *auratus* of Linnæus. The form of this fish resembles the carp; its nostrils are tubular; the tail is naturally bifid, but in many is trifid, and in some quadrifid; the anal fins are placed opposite to each other like the ventral fins, which disposition constitute the most distinguishing character of this species: the colours are various; some are marked with a fine blue, with brown, with bright silver; but the general predominant colour is *gold* of a surprising splendor. They were first introduced into England about the year 1691, but not generally known before 1728. In China, the most beautiful kinds are taken in a small lake in the province of Che-Kyang, and are said to grow to the size of our largest herring; with us they have been known to arrive at the length of eight inches. Pennant.

GOLD *fish* is also a name by which some authors have called the *mineæ* or THAE, from the yellow colouring it frequently has on the covering of the gills.

GOLD *of pleasure*, *myagrum*, in *Botany*, a genus of the *tetradynamia siliculosa* class. Its characters are these; the empalement of the flower is composed of four oblong coloured leaves; the flower hath four roundish obtuse petals, placed in form of a cross; it hath six stamina the length of the petals, four of which are a little longer than the other; in the centre is situated an oval germen, which afterward becomes a turbinated, heart-shaped, little pod, having two valves, with the rigid style in the top, including roundish seeds. Miller enumerates five species, and Linnæus eight.

This plant is possessed of the same virtues with the *rapistrum*, but is not recommended for any particular purpose. The oil, however, obtained from it by expression, is excellent for rendering the skin soft and smooth.

GOLDEN, something that has a relation to gold, or consists of gold, in valuable like gold, or the like.

GOLDEN *Bull*, *Bulla aurea*. See BULL.

GOLDEN *Calf* was a figure of a calf, which the Israelites cast in that metal, and set up in the wilderness to worship, during Moses's absence in the mount, and which that legislator, at his return, burnt, ground to powder, and mixed with the water the people were to drink of, as related Exod. xxxii.

The commentators have been greatly divided on this article: the pulverizing of gold, and rendering it potable, is an operation in chemistry of the last difficulty; and it is hard to conceive how it should be done at that time, before chemistry was ever heard of, and in a wilderness too! many, therefore, suppose it done by a miracle; and the rest, who allow of nothing supernatural in it, advance nothing but conjectures as to the manner of the process.

Moses could not have done it by simple calcination, nor amalgamation, nor antimony, nor calcination; nor is there one of those operations that quadrates with the text.

M. Stahl has endeavoured to remove this difficulty. The method Moses made use of, in making his *aurum potabile*, according to this author, was the same with that which now obtains; only, instead of tartar, he made use of the Egyptian natron, which is common enough throughout the East.

GOLDEN *cups*, a name by which some call the RANUNCULUS, or *crow-foot*.

GOLDEN *eye*, in *Ornithology*. See DUCK.

GOLDEN *eye*, a species of fly. See CHRYSOPIL.

GOLDEN *fleece*, in the *ancient Mythology*, was the skin or fleece of the ram, upon which Phryxus and Hella are supposed to have swam over the sea to Colchis; and which, being sacrificed to Jupiter, was hung upon a tree in the grove of Mars, guarded by two brazen-hoofed bulls, and a monstrous dragon that never slept; but at last taken and carried off by Jason and the ARGONAUTS. Many authors have endeavoured to shew, that this fable is an allegorical representation of some real history, particularly of the philosophers stone.

Order of the GOLDEN *Fleece* is a military order, instituted by Philip the Good, duke of Burgundy, in 1429.

It took its denomination from the representation of the *golden* fleece, borne by the knights on their collars, which consisted of flints and steels. The king of Spain is now grand-master of the order, in quality of duke of Burgundy: the number of knights is fixed to thirty-one.

It is usually said to have been instituted on occasion of an immense profit which that prince made by wool; though others will have a chemical mystery couched under it, as under that famous one of the ancients, which the adepts contend to be no other than the secret of the elixir, written on the fleece of a sheep.

GOLDEN *flower gentle*, a name sometimes given to several species of the AMARANTH.

GOLDEN *head*, in *Ornithology*, a water-fowl, otherwise called *anas acuta*. See DUCK.

GOLDEN *lung-wort*, in *Botany*. See HAWKWEED.

GOLDEN *maiden-hair*. See ADIANTUM *aureum*.

GOLDEN *mouse-ear*. See HAWKWEED.

GOLDEN *Number*, in *Chronology*. See CYCLE *of the moon* and NUMBER.

GOLDEN *prebendary of Hereford*. See PREBENDARY.

GOLDEN *rod*, or *Saracen's* WOUND-WORT, *virga aurea*, or *solidago*, in *Botany*, a genus of the *syngenesia polygamia superflua* class. Its characters are these: it has a compound flower, made up of hermaphrodite florets and female half florets, inclosed in one long imbricated empalement; the hermaphrodite flowers, which compose the disk, are funnel-shaped, cut into five parts at the brim; they have five very short hair-like stamina, terminated by cylindrical summits; and a crowned germen, supporting a slender style as long as the stamina, crowned by a bifid open stigma; the germen afterward turns to a single seed, crowned with hairy down; the female half florets are tongue shaped, indented in three parts; these have a crowned germen with a slender style, crowned by two revolving stigmas, and are succeeded by a single seed, like the hermaphrodite florets. Miller enumerates thirty-three species, and Linnæus fourteen.

We have several very beautiful species of this plant cultivated in our gardens, where they are very great and lasting ornaments, beginning to flower in May, and one kind or other of them continuing to flower till October. They are all easily propagated by parting their roots in spring, before they begin to shoot; they will grow in any soil or situation, but they succeed best in a light fresh earth and an open exposure, and should be planted in the middle of large flower-beds: they are perennial plants, dying down to the ground as soon as they have ripened their seeds, but rising again the following spring: these seeds sown will very freely grow, and often produce varieties in the flower. Miller.

The species of *golden rod*, called the *virga aurea angustifolia minus serrata*, or narrow-leaved *golden rod* less fawed, with linear spear-shaped leaves almost entire, and flowers in clusters sitting close at the wings of the stalk, grows wild in woods and heaths, and flowers in August.

The flowers and leaves of this species are recommended as corroborants and aperients, in urinary obstructions, nephritic cases, ulcerations of the bladder, cachexies, and incipient dropsies. It communicates its virtues to water and spirit. The extracts are the best preparations. Lewis.

GOLDEN *rod tree*. See BOSEA.

GOLDEN *Rule*, in *Arithmetic*, a rule or praxis of great use and extent in the art of numbers, whereby we find a fourth proportional to three quantities given. The *Golden Rule* is also called the *Rule of Three* and *Rule of Proportion*. See its nature and use under the article RULE *of Three*.

GOLDEN *samphire* is a species of the *inula* or ELECAMPANE, with narrow fleshy leaves ending in three points. It grows naturally on the sea-coasts in many parts of England, and is sometimes sold in the London market for the true SAMPHIRE, though entirely destitute of its warm aromatic taste.

GOLDEN *saxifrage*. See *Golden* SAXIFRAGE.

GOLDEN *Stole*, *order of the*. See STOLE.

GOLDEN *sulphur of antimony*. See ANTIMONY.

GOLDEN *thistle*, in *Botany*. See *Golden* THISTLE.

GOLDSINNY, in *Ichthyology*, a fish discovered on the coast, of Cornwall, in the whole form of the body, lips, teeth, and fins, resembling the WRASSE, which is said never to exceed a palm in length; near the tail is a remarkable black spot; the first rays of the dorsal fin are tinged with black. Pennant.

GOLDYLOCKS, *chrysocoma*, in *Botany*, a genus of the *polygamia polygamia æqualis* class. Its characters are these: the flower is composed of many hermaphrodite florets, contained in an imbricated empalement, which are tubular and funnel-shaped, cut into five parts at the brim, and have five short slender stamina; they have an oblong germen, which becomes a single, oblong, compressed seed, crowned with hairy down. Miller reckons five species, and Linnæus nine.

GOLDYLOCKS is also a name sometimes given to the GNAPHALIUM.

GOLF, or GOUF, the name of a diversion or exercise, much used in Scotland, and played upon the lawns or links, as they are there called.

It consists in driving a ball with clubs, between two goals or holes, half a mile or a mile asunder. He who can do this with the fewest strokes of his club is the conqueror.

GOLPS, in *Heraldry*, are roundles or torteaux, of a purple colour.

GOLTBERGENSIS *terra*, in the *Materia Medica*, a whitish earth, used in the shops of Germany and Italy as an astringent, a cordial, and a sudorific, but little known among the English apothecaries. It is dug in many parts of Germany, as Goldberg and Striegow, and Lignitz in Silesia; but particularly at this time in the neighbourhood of Hasleck, in the bishoprick of Liege, in the circle of Westphalia. It is taken up there in considerable quantities, and usually is sealed with the impression of an eagle, and with its old name *Goldbergensis terra* under it. It was imagined to contain some particles of silver, and thence to derive some of its virtues: on this account Montanus called it *aurugin lunæ*, but experience shews that it doth not contain a particle of that metal. It is a dense compact earth of a dull greyish white, soft and friable, and adheres firmly to the tongue, and makes no effervescence with acids.

GOMARA, or GOMARIS, in *Natural History*, a name given by some of the old authors to *talc*; some have also called it *gumara*: this last seems only a corruption of the word *gomaris*, and that of *ermaras* or *tomaris*, a name this stone was often called by among the Greek writers of the middle ages. Some have also called the selenites by this name, and it seems to have originally belonged to that fossil, but both being foliaceous fossils, both were often confounded together.

GOMATUS, in *Ichthyology*, a name used by many for the GURNARD, more frequently called by authors *gurnardus*.

GOMER, or OMER, an Hebrew measure. See CORUS.

GOMPHOSIS, in *Anatomy*, a kind of ARTICULATION of the bones, wherein one is chafed, or fitted immoveably into another, after the manner of a peg or nail.

The word is *γομφωσις*, formed of *γομφος clavus, a nail* or *peg*.

The teeth are set in the jaws by *gomphosis*. See TEETH and MAXILLA.

GOMPHRENA, in *Botany*, *globe amaranth*, a genus of the *pentandria digynia* class. Its characters are these: the flower hath a large coloured empalement, which is permanent; the petal is erect, and cut into five parts at the brim, which spread open; it hath five stamina, scarcely discernible, situated in the brim of the nectarium; in the centre is situated an oval pointed germen, which becomes one large roundish seed, inclosed in a thin crusted capsule with one cell. There are seven species, natives of the East and West Indies. See AMARANTHOIDES.

GOMUTURA *fossilia*, in *Natural History*, the name given by the Indians to a kind of fossil, found in great plenty on the mount Vindy in the East Indies, in places, as they observe, where the cows frequently urine. It is a bituminous substance, and after calcination the residuum is given in cases of internal ulcers and in gonorrhœas. The Indians suppose it is formed by the drying up of the cow's urine.

GONAGRA, in *Medicine*, the gout in the knee. See GOUT.

The word is composed of *γονυ, knee*, and *αγρα, capture, seizing*.

GONAMBUCH, in *Ornithology*, a name by which many called the *guaxumbi*, or HUMMING-*bird*, the smallest of all birds.

GONANDINA, the name of a Brasilian tree, remarkable for its great height.

GONARCHA, a term in the ancient dialling. Mr. Perrault, in his notes on Vitruvius, lib. ix. cap. 9. takes the *gonarcha* to have been a kind drawn on divers surfaces or planes; some of which being horizontal, others vertical, others oblique, &c. formed divers angles.

Whence the appellation, from *γονυ, knee*, or *γωνια, angle*.

GONDOLA, a little flat BOAT, very long and narrow, chiefly used at Venice to row on the canals.

The word is Italian, *gondola*. Du-Cange derives it from the vulgar Greek *κονδουρι, a bark*, or *little ship*; Lancelot deduces it from *γονδ*, a term in Athenæus for a sort of vase.

The middle sized *gondolas* are upwards of thirty feet long, and four broad: they always terminate at each end in a very sharp point, which is raised perpendicularly to the full height of a man.

The address of the Venetian gondoliers, in passing along these narrow canals, is very remarkable: there are usually two to each *gondola*, and they row by pushing before them. The fore-man rests his oar on the left side of the *gondola*: the hind-man is placed on the stern, that he may see the head over the fore: covering of the *gondola*, and rests his oar, which is very long, on the right side of the *gondola*.

GONDOLA is also the name of a pallage-boat of six or eight oars, used in other parts of the coast of Italy.

GONDOLA-*fish*, in *Natural History*, a name given by authors to a peculiar kind of *ensis gladius*, supposed, in some degree, to represent the shape of a Venetian boat. It is of the genus of the BALTHUS, and there are seven species of it.

GONFALON, or GONFANON, a kind of round tent, borne as a canopy, at the head of the processions of the principal churches at Rome, in case of rain; its verge of banner serving for a shelter, where there is not a great deal of attendance.

GONGOLARA, in *Botany*, a name by which Imperatus has called a very beautiful ica plant, known among botanical writers by the name of *ficus crista gallis*, or ERICA *marina*, the sea heath.

GONGRONA, a word used by many authors to express a round and hard tubercle in the trunk of a tree: it is also used in medicine to express any round and hard tumour of the nervous parts, but principally a bronchocele.

GONIOMETRICAL *lines*, derived from *γωνια, angle*, and *μετρεω, I measure*, in *Geometry*, lines used for measuring or determining the quantity of angles. Such are lines, tangents, secants, versed lines, &c.

We have a paper by Mr. Jones, in the Philosophical Transactions, containing a commodious disposition of equations for exhibiting the relations of *goniometrical* lines, from whence a multitude of curious theorems may be derived. See Phil. Trans. N° 283. sect. 26.

GONIPON, in *Ichthyology*, a name given by the French to the common GUDGEON.

GONIOSIS, a term used by Archigenes to express a peculiar sort of pulse, which seems to strike, not with the whole circle of the artery, but with an angle of it; or when the elevated artery is not felt like the curve of a circle, but like the vertex of a triangle. The cause of this is an imbecillity in the motion of the blood, which renders it incapable of elevating the whole artery.

GONORYNCHUS, in *Ichthyology*, a species of cyprinus with eight rays in the anal fin, a cylindric body, and bifid tail. It is found at the Cape of Good Hope.

GONORRHŒA, *Venerea*, in *Medicine*, an involuntary flux or dripping of seed, or other humour, by the penis, without erection or titillation.

The word is formed of the Greek *γονος, genitura, seed*; and *ῥεω, flow, I flow*.

The *gonorrhœa* is of two kinds; the one *simple* or *benign*, the other *virulent* or *venereal*.

GONORRHŒA, *simplex*, or that without virus or malignity, takes its rise from violent exercises and trainings, the immoderate use of hot foods and spirituous liquors, cold, violent or frequent purging, excessive coition, &c. It is cured by indulging, nourishing foods, broths, &c.

This species is again divided into two; the one *true*, the *gonorrhœa vera*, wherein the humour discharged is real seed; the other *spurious*, the *gonorrhœa nothæ*, wherein the dripping humour is not seed, but a whitish and mild matter from the glands about the PROSTATÆ and URETHRA.

This latter kind bears some resemblance to the fluor albus or whites in women, and frequently remains a long time without much diminution of the patient's strength. Some call it a *catarrhal gonorrhœa*. Its seat is in the glands of the prostatæ and urethra, which are either too much relaxed, or ulcerated. See GLEET.

GONORRHŒA, *virulenta*, *gonorrhœa virulenta*, arises from some impure commerce, and is the first stage of the venereal

venereal disease, being what we popularly call a CLAP. The parts here primarily affected, are the prostate in men, and lacunæ in women, which, being ulcerated by some contagious matter received in coition, occasion an itching, with a small degree of pain in the genitals, and then emit, first, a whitish watery liquor that stains the linen with spots, whose edges are of a darker colour than the centre, accompanied with a small degree of titillation, particularly at the time of making water, and, by degrees, with greater heat and more acute pain, perceived chiefly at the extremity of the urinary passage, where a slight degree of redness and inflammation likewise begins to appear: this liquor afterwards grows yellowish, then sharper, and at length greenish or bluish, sometimes of a bloody colour, and frequently fetid.

It is attended with a tension and inflammation of the yard, and an ardor urinæ, or sharpness of urine, which gives a painful sensation in the condition, and is discharged sparingly and with difficulty; the urinary passage being torn and excoriated by the acrimony of the humour.

Hence arise tumors of the prepuce and glands, with ulcers on the same; and sometimes in the urethra.

The cause of the virulent *gonorrhœa*, according to M. Littre, is some sharp or acid humour, heated, vitrified, and raised at the time of coition, from the internal parts of the gudendum of a woman infected, and lodged in the urethra of the man. It has different seats in the body: sometimes it only lies on Cowper's mucous glands, sometimes on the prostatæ, and sometimes on the vesiculæ seminales; sometimes it possesses two, and sometimes all three of those places at once.

From this diversity of seats of the *gonorrhœa virulenta*, M. Littre makes two sorts; *simple*, which only affects one of the three parts; *compound* or complicated, where several are affected.

That seated in the mucous glands, he observes, may remain simple through the whole course of the disease, because the mouths of those glands open into the urethra an inch and half on this side the prostatæ, and also look down towards the glands, so that their liquor is easily discharged. The other two sorts mutually produce each other, because the ducts of the vesiculæ seminales terminate in the urethra in the middle of those of the prostatæ, so that there is an easy communication between them.

That seated in the mucous glands is much the rarest case, and is the easiest cured. The cure is effected by emollient cataplasms and fomentations upon the part, and a half-bath. Mem. de l'Acad. ann. 1711.

For the other species more powerful means are to be used. The principal remedies are mercurial purges, an emulsion of green hemp-seed, cuttle-fish-bone, turpentine, sacch. saturni, &c. We have likewise great commendations of green precipitate of mercury and mercur. dulcis. Half. saturni terebinthinatum, prepared with a gentle fire, of sacch. saturni and oil of turpentine, is much applauded, where the heat is great about the reins and genitals; as also camphor. An infusion of cantharides in wine is the nostrum of a noted Dutch physician. Resin of the wood guaiacum is also recommended; and balsam of Copaiba is held a sort of specific: to which must be added antimonium diaphoreticum, bezoardicum minerale, water wherein mercury has been boiled, injections of lime-water, mercurius dulcis, saccharum saturni, &c.

Pitcairn's method of curing the *gonorrhœa virulenta*, is as follows: in the beginning of the disease he purges with a laxative ptisan of senna, salt of tartar, and sulphur-flowers; and gives the patient whey for his drink. After three or four days spent in this purging, if the scalding of the urine and the flux be abated, and the colour and consistence of the matter improved, he administers boluses of turpentine and rhapnticum for six or seven days; and if they keep the body loose, so much the better. By all means, astringents are to be avoided; the *gonorrhœa* being scarce ever known to degenerate into a pox, unless too hastily stopped.

Du Bleguy directs the cure of the *gonorrhœa* to begin with a gentle cathartic of cassia, senna, crystal mineral, tamarinds, aethes, and rhubarb, administered every other day; then diaretics, particularly those of turpentine, and lastly, gentle astringents, as mineral waters, crocus martis astringens, tincture of roses, tincture of coral in cochineal, &c.

A slight injection may sometimes be carried off in a few days by bathing the parts with warm milk and water, and injecting frequently up the urethra a little sweet oil or linseed tea, warmed to the degree of new milk. Astringent injections should be very cautiously used, and only in a slight and recent stage of the disorder; an injection of this kind may be prepared by dissolving half a dram of the sugar of lead in six or seven ounces of rose-water; and a small syringe full of it, a little warm, may be injected up the urethra five or six times a day, and continued till the running stops. Gentle cooling purges are always proper in the *gonorrhœa*: for this purpose, the patient may take six drams, or an ounce of salts, and half an ounce of manna, dissolved in a pint of boiling water, whey, or water-gruel, early in the morning: or, two drams of senna and an ounce of tamarinds may be infused all night in a pint of boiling water, and half an ounce of Glauber's salts dissolved in the strained infusion; and a tea-cup of this may be taken every half hour till it operates. Or, the patient may take two or three tea-spoonfuls of the following electary at night, and the same quantity in the morning: take of the lenitive electary four ounces, cream of tartar two ounces, powdered jalap two drams, rhubarb one dram, and as much of the syrup of roses as will serve to make the whole into a soft electary.

When the symptoms of inflammation are high, bleeding is always necessary at the beginning. Diuretics are also proper in this stage of the disorder: an ounce of nitre, and two ounces of gum Arabic, pounded together, and divided into twenty-four doses, one of which may be taken frequently, will answer this purpose: or, equal parts of gum Arabic and cream of tartar, pounded together, and taken four or five times a day, in the quantity of a tea-spoonful, will serve both as a diuretic and laxative.

Emollient clysters are very useful, when the pain and inflammation are seated high towards the neck of the bladder; and soft poultices, made of the flower of linseed, or of wheat bread and milk, softened with fresh butter, or sweet oil, or cloths wrung out of warm water, or bladders filled with warm milk and water, may be applied with great benefit. If this treatment fails to effect a cure, the patient must have recourse to the use of mercury: two at night and one in the morning of the common mercurial pills will be a sufficient dose at first, which may be diminished or increased according to its effect: or, two or three grains of calomel may be formed into a bolus with the conserve of hips, and taken at bed-time, and the dose gradually increased to eight or ten grains: or, again, corrosive sublimate may be taken in the manner prescribed under VENEREAL *disease*. These mercurial medicines should never be taken in such quantities as to raise a salivation, unless in a very slight degree: for preventing which, they may be combined with purgatives; and the griping or purging of the mercury may be prevented by taking with the above pills or bolus half a dram or two scruples of DIASCORDIUM, or of the Japonic confection. See CONFECTIO *Japonica*. Mercury may be taken in a liquid form, by rubbing a dram of it with two drams of gum Arabic reduced to a mucilage in a marble mortar, till the mucilage disappears, and adding gradually during the trituration, half an ounce of balsamic syrup, and eight ounces of simple cinnamon water: two table-spoonfuls of this solution may be taken night and morning. Mercury may also be administered by means of friction: a dram of mercurial ointment, prepared by rubbing together equal quantities of hog's lard and quicksilver, may be used at a time. The best time for rubbing it on the body is at night, and the most proper place is the inner side of the thighs. In whatever way mercury is administered, its use must be persisted in as long as any virulency is suspected to remain. When, by the proceding treatment, the pain and heat are abated, and the quantity of the discharged matter is lessened, and it is become whitish, thick, and void of ill smell, which symptoms constitute the third or last stage of the *gonorrhœa*, astringent or agglutinating medicines may be cautiously used: but it is dangerous to stop the running till the contagion is removed, because, in this case, swelled testicles, a sore throat, buboes, or some other symptoms of the pox, will ensue; and, when this happens, the discharge must be again promoted by purges, and more mercury must be used. At first, therefore, it may be proper to mix gentle astringents with purgative medicines: thus, to two ounces of the lenitive electary add cream of tartar and powdered rhubarb, of each half an ounce, and balsam of Capivi an ounce and a half; take of these, made into an electary with the syrup of pale roses, about the quantity of a large nutmeg, evening and morning: the patient may then proceed to the use of Venice turpentine, the Peruvian balsam, balsam of Gilead, &c. or, instead of these, he may take fifteen or twenty drops of the acid elixir of vitriol in a glass of red wine, or a cup of the infusion of the bark, twice or thrice a day. If the running still continues, without any signs of virulency, injections may be used: for this purpose gum Arabic may be dissolved in three or four ounces of rose-water, and ten or twelve grains of *sugar of lead* may be added to the solution: two or three drams of

this, made a little warm, and adapted in strength to the nature of the case, may be daily injected up the urethra with a small syringe. If all these means should fail to stop the discharge, though the virulence is entirely removed, the disorder is denominated a GLEET.

Regard must be paid to the regimen in the several stages of the *gonorrhœa*. In the first stage, the person, who suspects that he has been infected, should observe a cooling regimen, and avoid every thing of a heating nature, as wines, spirituous liquors, rich sauces, spiced, salted, high-seasoned, and smoke-dried provisions, and also all aromatic and stimulating vegetables, as onions, mustard, cinnamon, ginger, &c. His food should consist chiefly of mild vegetables, milk, broths, puddings, gruels, &c. his drink may be barley-water, milk and water, decoctions of marsh-mallows and liquorice, linseed tea, or clear whey, which he should use freely. He should avoid violent exercise and cold. When the inflammation has subsided, or in the second stage of the disorder, all intemperance should be avoided: the food should be light, plain, and of eafy digestion; and a little wine, diluted with much water, may be allowed, but spirituous liquors are dangerous. In the last stage, the patient should use moderate exercise in the open air; his diet should be rice, millet, jellies, and other things of a strengthening nature: his drink may be Bristol water, claret or port with the addition of water. Buchan's Domestic Med. p. 534, &c. See VENEREAL *disease*.

GONYALGIA, of γονυ, *knee*, and αλγος, *pain*, a term used by some authors to express a violent pain in the knee.

GOOD, or GOODNESS, denotes whatever tends or conduces to preserve or improve human nature or society; in opposition to *evil*, which tends to destroy, injure, or impair the same.

Hence *good* is divided by the philosophers into, 1. *Bonum sui*, private *good*; which is that whereby a thing tends to preserve, &c. itself; under which comes that popular division of *goods* of body, mind, and fortune.

2. *Bonum communionis*, whatever promotes the interest and welfare of society; as all the civil offices, &c.

GOOD, in *Metaphysics*, or *metaphysical* GOOD, called also *absolute* or *real* GOOD, and GOOD *per se*, is the essential perfection or integrity of a thing, whereby it has every thing that belongs to its nature.

In this sense, all things that are, are *good*, inasmuch as they have the perfections naturally belonging to things of their kind. Thus, a thinking substance is *good*, or perfect, as it has all the essential attributes of thought; so an extended substance is *good*, as it possesses all the parts necessary to constitute it such.

In effect, as it is absurd to imagine a being without its essence, so is it to imagine a being without the requisites of its essence; so that it appears an error in some philosophers, who divide beings into good or perfect, and evil or imperfect. See ESSENCE.

Others define metaphysical, or transcendental *goodness*, by congruency with the divine will, which, they say, constitutes the measure of all real *goodness*.

GOOD, *physical* or *natural*, is that whereby a thing possesses all things necessary to its *bene esse*, i. e. its well-being, or second perfection, and to the performance of its functions and uses.

In this sense, physical *goodness* coincides with physical perfection.

To this are required the several powers and faculties, in their proper degree; a due situation, figure, and proportion of parts, &c.

Note, beside absolute physical *goodness*, there may be a *relative* one; as in foods, which to one are salutary, to another poison, &c. To this head also belong the things *good pro tempore*, or according to circumstances; as the amputation of a mortified limb, &c.

Natural *good* may be otherwise defined to be that which makes or denominates a being happy, or prepares him for happiness; or, at least, prevents or removes his misery: accordingly, *good* is either objective or formal; objective *good* is that which makes us happy; formal *good*, or the pleasure resulting from the application of the faculty to the object, is that which denominates us happy.

GOOD, *moral* or *ethical*, is the agreement of a thinking, reasonable being, and of the habits, acts, and inclinations thereof with the dictates of right reason, and the will of the Creator, as discovered by natural light. See VIRTUE.

In order to this, it is not enough that a thing done, said, thought, desired, be just and *good*; but it must be done, thought, &c. well, i. e. from *good* principles, and to *good* ends.

Others define moral *good* more largely. *Moral*, which they also call *relative good*, according to them, is something that is good to another, or that tends some way to the perfection thereof. In this sense they divide it into three kinds, *honestum*, *jucundum*, and *utile*.

The first, *bonum honestum*, is what agrees with right reason, and is desirable for itself; as all things virtuous; e. g. to love God, respect our parents, &c. It is considered without any regard to pleasure; not but there is sometime pleasure annexed to it. Zeno and the Stoics allow of no other *goods*; those of the body, &c. they call *commoda*, *convenientia*, not *goods*.

Bonum jucundum is that which is *good*, as it tends to give us pleasure, and is desired on that account; but without any repugnancy to virtue or right reason; as ariseth to the ears, painting to the eyes, &c.

Bonum utile, or *commodum*, is that which is *good* on account of something else for which it is desired; as money, riches, &c.

GOOD, *chief*, *sovereign*, or *supreme*, *summum bonum*, is that, the enjoyment of which renders men truly and completely happy. The schools distinguish this chief *good* of man into that which is simply and adequately so, and beyond which there can be no other; and an inferior, subordinate kind, which is, in some measure, attainable in this imperfect state. This last they call *felicitas viatoris*, and the former *felicitas comprehensoris*. The chief or sovereign *good*, according to the idea collected of it from the original, natural, and universal preconceptions of all mankind, is something agreeable to our nature, conducive to well-being, accommodable to all places and times, durable, self-determent, and indestructible: and this remains, says Mr. Harris, in rectitude of conduct, or in living perpetually seeding, as far as possible, what is congenous to nature, and rejecting what is contrary, making our end that selecting and rejecting only. Three Treatises, &c. 1765, p. 121, &c. 209, &c.

Philosophers are divided as to what the chief *good* of man consists in: whether in the *goods* of fortune, of body, or of mind. Some hold riches and honours the supreme *good*; others, as Aristippus, and the Cyrenaic school, bodily pleasures; and others, as Zeno, and the Stoics, virtue, or living according to nature. The Peripatetics agreed with the Stoics in maintaining that virtue is the *summum bonum*: but the Stoics asserted further, that virtue was the *only good*; whilst the Peripatetics denied, with reason, that virtue was self-sufficient, and therefore required several other things as auxiliaries, such as health, prosperity, friends, &c. which are in the virtuous man in the nature of instruments or ornaments to his felicity. An excellent writer lays down the following *criteria* or characteristics of the *summum bonum*, or *chief good*, which reason can demonstrate to be actually designed for man: it is something which all men, if not wanting to themselves, may be possessed of: it is one and the same to all mankind: and while in itself fitted to make the possessor happy, is not prevented in its operation by some other thing which keeps him from relishing it: and as to the highest *good* which it is possible for man to enjoy, it must be referred to no other, but all others must be embraced for the sake of this: and it must be sufficient to furnish a happiness adequate to the capacities of human nature, and of equal duration: i. e. it must be not only perfect whilst it lasts, but everlasting. According to these characters we may infer, that neither the *goods* of fortune, nor those of the body, nor even virtue itself, constitute the *chief good*. Virtue rightly understood is the perfection of human nature: it is the instrument of obtaining happiness: but this alone will not make a man happy: it is further necessary that he be perfect as to life, or happy in the circumstances of his being: and, therefore, natural reason demonstrates, that the favour of God, secured by virtue, is properly man's *supreme good*. Grove's System of Moral Philosophy, vol. 1. part ii. passim. See EPICUREANS, PERIPATETICS, and STOICS.

GOOD-*will*. See BENEVOLENCE.

GOOD *works*. See MERIT and SUPEREROGATION.

GOOD *abearing*, *bonus gestus*, in a *Law Sense*, is particularly used for an exact carriage or behaviour of a subject towards the king and his liege people; to which some men, upon their misbehaviour, are bound.

The justices are empowered by 34 Edw. III. cap. 1. to bind in this manner all them that be not of good fame; under which general expression, it is holden that a man may be bound to his *good behaviour* for causes of scandal, *contra bonos mores*, as well as *contra pacem*; as, for haunting bawdy-houses; for keeping bad women in his own house; or for words tending to scandalize the government, or in abuse of the officers of justice, especially in the execution of their office: a justice may also bind over all night-walkers, eaves-droppers, such as keep suspicious company, or are reported to be pilferers and robbers, common drunkards, whore-masters, the putative fathers of bastards, cheats, idle vagabonds, and any other persons,

persons, whose misbehaviour may reasonably bring their within the general words of the statute. Persons of this description may be bound, with one or more sureties, in a RECOGNIZANCE or obligation to the king, entered on record, and taken in some court, or by some judicial officer, whereby the parties acknowlege themselves to be indebted to the crown in the sum required, e. gr. 100l with condition to be void and of none effect, provided that they behave themselves well, either generally or specially, for the time therein limited, as for one or more years, or for life. This recognizance, if taken by a justice of the peace, must be certified to the next sessions, by 3 Hen. VII. cap. 1, and if the condition of it be broken, the recognizance becomes forfeited or obliolate; and being estreated or extracted, i. e. taken out from among the other records, and sent up to the exchequer, the party and his sureties are become the king's debtors, and are sued for the several sums in which they are bound. All persons under the king's protection may obtain such security, upon due cause shewn; and the justice may be compelled to grant it by a mandatory writ, called SUPERSEDEAS: but this writ is seldom used, for, when application is made to the superior courts, they usually take the recognizances there, under the direction of the statute 21 Jac. I. cap. 8. A recognizance may be discharged, either by the demise of the king, or by the death of the principal party bound thereby, or by order of the court to which it is certified by the justices. He that is bound to the GOOD behaviour, is more strictly bound than to the PEACE; because, whereas the peace is not broken without an affray, battery, or such like, this surety *de bono gesto* may be forfeited by the number of a man's company, or by his or their weapons or arms, by speaking words tending to sedition, or by committing any of those acts of misbehaviour which the recognizance was intended to prevent.

GOOD *ale*. See ALE.

GOOD *behaviour*. See GOOD *abearing* and PEACE.

GOOD *tale*. See TALE.

GOODS, *bona*, in *Law*, and particularly the *Civil Law*, include all kinds of effects, riches, funds, possessions, &c. There are two kinds of *goods*; *moveable*, *res mobiles* or *mobiles*; and *immoveable*, called *res non mobiles* or *immobiles*.

It is a maxim in the civil jurisprudence, that he who confiscates the body, confiscates the *goods*; meaning, that all the effects of a person condemned to a capital punishment, or perpetual banishment, are forfeited to the king.

A man is said to bind himself, body and *goods*, meaning, that besides his *goods*, he obliges his person, and submits to remain in prison, provided he do not execute his promise.

Goods, again, are divided into, 1. *proper*, *paternal*, *patrimonial*, *hereditary*; 2. *acquired* or *acquesti*, *also quam hæreditate non acquisita*; and, 3. *conquesti*, *vere & usere plante facilate acquisita*.

Goods, again, are divided into *real* and *personal*. See CHATTELS and ESTATE. And, lastly, *into nobis or* FREE, and *servile or* BASE.

Goods belonging to the domain of the crown, *ad filum spectantia*, cannot be alienated for ever, unless it be done by way of exchange: they may be sold under the faculty of perpetual redemption.

GOODS, *adventitious*, *adventitia*, are those which arise otherwise than by succession from father or mother, or from direct ancestor to defcendant. See ADVENTITIOUS.

GOODS, *dotal*, *dotalia*, those accruing from a dowry, and which the husband is not allowed to alienate. See DOWER.

GOODS, *fugitives*. See FUGITIVE.

GOODS, *paraphernal*. See PARAPHERNALIA.

GOODS, *prohibited*. See PROHIBITED.

GOODS, *profectitious*, *profectitia*, are those arising by direct succession.

GOODS, *receptitious*, were those which the wife might reserve the full property of to herself, and enjoy them independently of her husband; so called, in distinction from *dotal* and *paraphernal goods*.

GOODS, *vacant*, *vacantia*, are those abandoned, or left at large, either because the heir renounces them, or that the deceased has no heir.

GOODS, *allotting of*. See ALLOTTING.

GOODS, *confinement of*. See CONFINEMENT.

GOODS, *running of*. See RUNNING.

GOODINGS, in *Scotch-ships*, are clamps of iron bolted on the fore-part of a ship, wherein to hang the rudder and keep it steady; for which purpose there is a hole in each of them, to receive a correspondent spindle bolted on the back of the rudder, which turns thereby as upon hinges.

GOOLE, a breach in a sea-bank or wall; or a passage worn by the flux and reflux of the sea. Vide 16 and 17 Car. II. cap. 11.

The word comes from the French *goulet*, the gullet or neck.

GOOSANDER, in *Ornithology*, the English name for the male MERGANSER; the female of that species having been universally esteemed a different bird, and called the DUNDIVER, and *mergus cirratus longirostres*.

GOOSE, *anser*, forms an order of birds in the Linnæan system. See ANSERES. The several species of *geese* belong to the genus of ANAS or DUCK under this order. The common or domestic *goose* is a variety of the *anser ferus*, or wild *goose*; and derived from the *grey leg*, or *tame-goose* of Ray, which is the only species that the Britons could take young and familiarize. The length of the *grey leg* is two feet nine inches, and the extent five feet: the bill is large and elevated, of a flesh-colour, edged with yellow; the nail white; the head and neck cinereous, mixed with yellow; the hind part of the neck very pale, and at the base a yellowish brown: the breast and belly are whitish, clouded with grey; the back grey; the lesser coverts of the wings almost white; the middle row deep cinereous, slightly edged with white; the primaries grey, tipt with black, and edged with white; the secondaries entirely black, and grey at their base; the scapulars of a deep ash colour, edged with white; the coverts of the tail and the vent-feathers of a pure white; the middle feathers of the tail dusky, tipt with white; the exterior feathers almost wholly white; the legs are of a flesh colour. This species resides in the fens during the whole year; breeds there, and hatches about eight or nine young, which are easily tamed, and their meat is much superior to that of the domestic *goose*. The common *goose* retains the whiteness of the coverts of the tail and vent-feathers of its wild state; but the variety of colours in the same fort is less than in the other. Tame *geese* are of vast longevity: Mr. Willughby mentions an instance of one that attained eighty years.

Multitudes of tame *geese* are kept in the fens of Lincolnshire; a single person will keep a thousand old *geese*, each of which will rear seven, so that towards the end of the season he will become master of eight thousand.

The *geese* are plucked five times in the year: the first plucking, in pursuance of this barbarous practice, is at Lady-day, for FEATHERS and quills; and the same is renewed, for feathers only, four times more between that and Michaelmas. See FOWL.

There is another variety of the wild *goose*, called, from the shape of the nail of its bill resembling a horse-bean, the *bean goose*, which is somewhat smaller than the *grey leg*, and distinguished from it by a smaller bill, much comprelled near the end, whitish, and sometimes pale red in the middle, and black at the base and nail. This species, which lights on corn-fields, and feeds much on the green wheat, comes to the fens in Lincolnshire in summer, never breeds there, but disappears in May. They fly very high, and make a cackling noise in their flight: they preserve a great regularity in their motions, sometimes forming a strait line, and at other times assuming the shape of a wedge, for their more easy progress through the air.

There is also another species of wild *goose* known in this country, called the *laughing*, or *white-fronted goose*, being the female *anas erythropus* of Linnæus, which is smaller than the former, and visits the fens and other parts of England during the winter, in small flocks: they keep always in marshy places, and never frequent the cornlands: these are never seen after the middle of March. Mr. Pennant observes, that the *goose* was one of the forbidden foods of the Britons in the time of Cæsar. Brit. Zool. vol. ii. p. 370, &c.

Besides these, there are other kinds of *geese*, which Linnæus enumerates as species of the ANAS: such are, 1. The *bernacle*, or BARNACLE, being the male *anas erythropus* of Linnæus. This is also in some places called CLARE. These birds appear in vast flocks during the winter, on the north-west coasts of this kingdom; they are very shy and wild, but, on being taken, grow as familiar as our tame *geese* in a few days: in February they quit our shores, and retire as far as Lapland, Greenland, and even Spitzbergen, to breed. They were formerly called *tree-geese*, from a mistaken notion that they were generated out of wood, or rather out of a species of shell, called the *lepas anatifera*, that is often found sticking to the bottoms of ships. Pennant.

2. The *brent-goose*, or BRENT. This is the *anas bernicla* of Linnæus. These birds frequent our coasts in the winter, and are called in Ireland *bernacles*, appearing in great numbers in August, and leaving it in March. They feed on the root of a long grass that grows in the water; are caught in nets placed across the rivers near Londonderry, Belfast, and Wexford, and much esteemed for

for their delicacy. Mr. Willughby, Mr. Ray, and M. Briſſon, deſcribe the *bernacle* and *brent* as different ſpecies; but Linnæus makes them ſynonymous. Pennant.

3. The *anſer Hiſpanicus*, or *ſwan-goſe*, being the *anas cygnoides* of Linnæus, which always moves in a ſtately manner, and with its head erect like a ſwan. Its back is of a brownish grey, its belly white, and its breaſt a little tinged with a reddiſh brown; and it has a line of blackiſh brown running ſtraight down the middle of the neck to the back.

4. The *anſer Gambenſis*, or *Gambo-goſe*, which in figure and ſize reſembles the *Muſcovy* DUCK, but has very long red legs, and a fine ſhining purple back; its belly is white, its beak red, and its head has a red caruncle: but its moſt obſervable character is, that it has a ſtrong ſpur ſtanding out from the firſt joint of the wings, as ſome of the Braſilian birds deſcribed by Margraave have. 5. The *anſer Canadenſis*, *Canada goſe*, or *anas Canadenſis* of Linnæus: this is of the ſhape of the common *goſe*, but a little longer in the body; its back is of a brownish grey, its rump black, its neck black at the bottom and white in every other part, its belly white, and its tail and wings black.

6. The *rat-goſe*, or *reed-goſe*, which is about half the ſize of the common *goſe*, and of a bluiſh grey on the back, and white at the belly. This is wild in the northern counties of England. Mr. Pennant ſuppoſes that this is the ſame with the *brent-goſe*.

7. The *anſer lanuginoſus*, or *anas nullifima* of Linnæus. See *Guthbert's* DUCK. Linnæus, Ray, and Pennant.

GOOSE, *timber*. See TIMBER.

GOOSE, *ſolland or ſolan*, ſometimes called GANNET, the Engliſh name of a large water-fowl, called by authors *anſer Baſſanus*, and by Linnæus *pelecanus Baſſanus*. This bird is remarkable for the quickneſs of its ſight; and, according to Martin, *ſolan* is derived from an Iriſh word expreſſive of that quality. See *Tab. II. Birds, fig.* 11.

It is of the ſize of the common *goſe*, and its wings are very long and capable of extending to a very remarkable breadth; its beak is long and ſtraight, and of a duſky grey, and a little hooked at the end: it has alſo near the hooked part two ſmall appendages like teeth: it is naked behind the eyes: its mouth opens to a great width, and it ſeems to have no noſtrils; but, in the place of them, has a long furrow running nearly the whole length of the bill; it has alſo a row of ſerratures or indentings all along, provided by nature for its holding fiſh more ſtamly: its feet are black, and all the four toes are connected by the ſame membrane: it is all over of a clear white when full grown, except that the larger wing-feathers have ſome blackneſs, and the head with age is apt to become yellow: its ſkin adheres but looſely to its fleſh, and the young are mottled with grey and brown: from the corner of the mouth is a narrow flip of black bare ſkin, that extends to the hind part of the head; beneath the chin is another, which, like the pouch of the pelican, is dilatable, and of ſize ſufficient to contain five or ſix whole herrings, which, in the breeding ſeaſon, it carries at once to its mate or young: it flies well, but if it fall on the ground does not eaſily raiſe itſelf. They are birds of paſſage, and build in the iſland of the Baſs in Scotland, and the rocks of St. Kilda, in vaſt numbers. Their firſt appearance is in March, and their continuance there till Auguſt or September; but, in general, the time of their breeding and of their departure ſeems to coincide with the arrival of the herring, and the migration of that fiſh, which is their principal food, out of theſe ſeas. It is probable that theſe birds attend the herrings and pilchards during their whole circuit round the Britiſh iſlands. They are known to migrate as far ſouth as the mouth of the Tagus, being frequently ſeen off Liſbon, during the month of December, plunging for ſardines, a kind of fiſh reſembling, if not the ſame with our pilchards. Each female, if undiſturbed, lays only one egg; but if that be taken away, it will lay another; and if that alſo is taken, a third; but never more that ſeaſon. The young *goſe* are eſteemed a great delicacy, and ſell at a great price. Ray and Pennant.

GOOSE, *Magellanic*, *anſer Magellanicus*, in *Ornithology*, the name given, though improperly, by Cluſius, to a bird of the diver kind. It is a ſea bird, and is uſually very fat; it is of the ſize of the largeſt *goſe*, and is black on the back and white on the belly: the neck is ſhort and thick, and has a ring or circle of white feathers round it: its ſkin is thick and tough like that of a hog, and it has only two coriaceous or leather-like fans in the place of wings, hanging from its ſide like two arms, covered with a few feathers which are ſhort and partly black, partly white, and by no means of any uſe to fly with, but very ſerviceable to the creature in ſwimming. It lives continually in the water, except at its breeding time; the tail is very ſhort, and the beak as large as a raven's, but not protuberating on the top, but flatted.

GOOSE-*dung*, in *Agriculture* and *Medicine*. See DUNG and CHENOCOPRUS.

GOOSE-*foot*, or WILD ORACH, or *Good Henry*, *chenopodium*, in *Botany*, a genus of the *pentandria digynia* claſs. Its characters are theſe: the flower has no petal, but in the centre hath five ſtamina placed oppoſite to the leaves of the empalement; it hath a round germen, which afterward becomes a five-cornered fruit incloſed in the empalement, containing one roundiſh depreſſed ſeed.

There are many ſpecies of this genus, ſome of which grow naturally on dunghills and the ſides of ditches in moſt parts of England, where they often become very troubleſome weeds.

The firſt ſpecies, called alſo Engliſh mercury, all-good, or good Henry, is found growing naturally in ſhady lanes, but it is doubtful whether the ſeeds have not been caſt out of gardens originally, becauſe this plant was formerly cultivated in kitchen-gardens; and in ſome of the northern countries the people ſtill preſerve it in gardens as an eſculent herb, which in the ſpring they boil as a ſubſtitute for ſpinage: but as the latter is a much better herb, it has juſtly obtained the preference.

GOOSE-*graſs*. See CLEAVERS.

GOOSE-*graſs*, *great*. See ASPERUGO.

GOOSE-*neck*, in *Sea-language*, is a ſort of iron hook fitted on the inner end of a boom, and introduced into a clamp of iron or eye-bolt, which encircles the maſt, or is fixed to ſome other place in the ſhip, ſo that it may be unhooked at pleaſure.

GOOSE-*wings of a ſail* denote the clues or lower corners of a ſhip's main-ſail or fore-ſail, when the middle part is furled or tied up to the yard.

GOOSE-*wing*, at *Sea*, a certain manner of fitting a ſail, which is thus performed: when a ſhip ſails before a wind, or with a quarter-wind, and in a freſh gale, the ſeamen ſometimes, to make the more bulg, unfurl the mizen-yard, and then they launch out both ſail and yard over the quarter on the lee-ſide, fitting guys at the farther end, to keep the yard ſteady with the boom, and this booms out the mizen-ſheet. This they do to give the ſhip the more way, which otherwiſe, with theſe winds, the mizen ſail could not do; and this ſail ſo fitted, is called a *goſe-wing*, and ſometimes a *ſtudding-ſail*.

GOOSEBERRY-*buſh*, *groſularia*, in *Botany*. Its characters are theſe: the flower has a permanent empalement, cut into five parts at the top, which is concave and coloured; it has five ſmall, obtuſe, creſt petals, which riſe from the border of the empalement; and five awl-ſhaped ſtamina, which are inſerted into the empalement; the germen is ſituated below the flower, and afterward becomes a globular berry, having a navel, with one cell, which is filled with roundiſh compreſſed ſeeds incloſed in a pulp. There are five ſpecies, including ſeveral varieties, bearing the names of the perſons who raiſed them. This is a ſpecies of the *ribes* in the Linnæan ſyſtem. See CURRANT-*tree*.

The *gooſeberry-buſh* is propagated either by ſuckers or cuttings, but the latter way is preferable, as the roots are leſs ſubject to ſhoot out ſuckers afterwards.

The beſt ſeaſon for planting the cuttings is in autumn, juſt before the leaves begin to fall; obſerving always to take the handſomeſt ſhoots, and to pick them from ſuch branches as produce the greateſt quantity of fruit. The cuttings ſhould be about ſix or eight inches long, and ſhould be planted in a bed of light earth expoſed to the morning ſun; they muſt be planted about three inches deep, and watered to help their taking root. The ſhoots ſhould be rubbed off from theſe plants as they put out, except thoſe at the top, that there may be a regular ſtem. In the October following, they ſhould be removed to a bed of fine light earth, and planted in rows at three feet diſtance, and one foot aſunder in the rows. They ſhould remain here one year, and the croſs branches at times be cut off, as alſo the lower ones, ſo as to keep a clean ſtem about a foot above the ground. Then will be then fit to plant out where they are to ſtand, which ſhould be in a light ſandy loam. They ſhould be kept from the ſhade of other trees; and to have the fruit in its utmoſt perfection, ſhould be ſet in an expoſed place in rows of eight feet aſunder, and each of the ſhrubs ſix feet from the others in the rows. The beſt time for tranſplanting them is in October, when the leaves begin to decay. Miller.

GOOSEBERRY *of Barbadoes*. See *Melon* THISTLE.

GOOSEBERRY-*tree*, *American*, *melaſtoma*, in *Botany*, a genus of the *decandria monogynia* claſs. Its characters are theſe: the flower has five roundiſh petals, which are inſerted into the border of a permanent empalement; and ten ſhort ſtamina, terminated by long recurved ſummits: under the flower is ſituated a roundiſh germen, which

turns to a berry with five cells, covered by the empalement which crowns it, and contains many small seeds. There are fixteen species, natives of the warm parts of America. Miller.

GOOSEBERRY-*gall*, in *Natural Hiſtory*, the name given by authors to a ſpecies of prouberances of the gall kind, found very frequently on the oak. They are of a roundiſh figure, and ſometimes adhere to the tree by a ſhort pedicle, but more frequently by a part of their ſpheric ſurface. They are uſually found on the under ſide of the leaves of the oak, but ſometimes on the young ſhoots, and ſometimes on the pedicles of the leaves.

They are moſt frequent in ſpring, but they are found at all times when the leaves are upon the trees. Theſe galls are greeniſh at firſt, and afterwards become yelloviſh, and finally red; in which laſt ſtate they very much reſemble the ſmall red *goſſeberry*. They are very ſoft to the touch, and when opened are found to contain a juicy ſubſtance, with a cavity in the midſt, in which there is lodged a ſingle inſect. This, according to the time in which the gall is opened, is found in the form of a white worm, or elſe of a white chryſalis, or finally of a ſmall ſhort-bodied four-winged fly of a black colour; for the creature does not leave the gall to go through any of its changes, but paſſes all its ſtates in it. The gall, in all theſe caſes, is found whole and unhurt; but if one is opened in which there is a hole pierced, this is ſure to be found empty, that being the paſſage by which the fly has made its way out. Reaum. Hiſt. Inſ. vol. vi. p. 214.

GOOSEBERRY-*worm*, in *Natural Hiſtory*, the name of an inſect, found very frequently on the *goſſeberry*-bushes, and uſually ſuppoſed to be a caterpillar, but differing eſſentially from that genus of animals, and being one of thoſe which the French call *fauſſe-chenilles*. It has a round head, and has twenty-two legs, and finally becomes not a butterfly, but a common four-winged fly. This worm is at firſt of a greeniſh colour, with ſome yellow variegations, and ſeveral black tubercles; but on the laſt change of its ſkin it becomes whitiſh or cream-coloured, and loſes its tubercles. Reaum. Hiſt. Inſ. vol. ix. p. 18.

GOR, a name given by ſome writers to a very lofty tree, which bears a fruit like the cheſnut; it grows principally on the banks of the river Niger, and that not near the ſea, but far up the country.

GOR-*cock*, in *Ornithology*, the name of a bird of the gallinaceous kind, called by authors the lagopus ultera, and by many the moor-cock, or red game; it is of the ſhape of the partridge, but is half as large again. Its beak is black and ſhort, and it is very remarkable for the bare ſpace over its eyes, which is very broad and of a fine bright red, and in the cock is ſurrounded by a prominence of the ſame bright colour, bare of feathers, and fimbriated like a cock's comb. The male is alſo diſtinguiſhed from the female, by having a black plumage at the baſe of the bill interſperſed with frequent white ſpots, and ſome large white ſpots near the origin of the under chap: the male is alſo redder than the female in all parts, and on his throat and breaſt is of a fair red, without the mixture of any other colour. The head, neck, back, and wings, are all variegated with red and black: the breaſt and belly are of the ſame colours with the back, but on the breaſt there are ſome variegations of white. The legs and feet are covered with a very long and thick plumage to the very ends of the toes; the wings are brownith, with ſome reddiſh variegations; and the tail is almoſt wholly black. It is ſeldom found but on the tops of very high hills, and is very common in Derbyſhire, Yorkſhire, and Wales, where it feeds on mountain berries and the tops of heath. It lays ſeven or eight eggs, which are of a mixed red and black colour, and are all over covered with ſmall ſpots, except for one or two ſpaces, which are clear near the ſmall end. The young brood follow the hen during the whole ſummer: in the winter they join in flocks of forty or fifty, and are remarkably fly and wild. This is a very well-taſted bird. The Italians call this, as well as the lagopus, by the common name of *francolins*, and Mr. Ray imagines that the lagopus of Pliny and this are indeed the ſame ſpecies of birds, though different in colour; but Mr. Pennant obſerves that the account left us by Pliny ſeems too brief and uncertain to determine, at this time, what ſpecies he intended, and that the *francolins* is not the ſame with our grous is evident from the figure exhibited of it by Mr. Edwards. Ray and Pennant.

GORAIS, in *Ichthyology*, a name uſed by ſome authors for the more common ſpecies of the CARASSIUS; the third ſpecies, as it is called by Gefner, &c.

GORCE, or GOURT, denotes a wear. By ſtat. 25 Edw. III. cap. 4. it is ordained, that all *gorces*, mills, weares, &c. levied or ſet up, whereby the king's ſhips and boats are diſturbed, and cannot paſs in any river, ſhall be utterly pulled down, without being renewed. Sir Edward Coke derives this word from *gorges*, *a deep pit of water*, and calls it a *gors*, or *gulf*; but this ſeems to be a miſtake, for in Doomſday it is called *gorst* and *gort*, the old French word for a *weare*.

GORDIAN, a term in *Hiſtory*. GORDIAN *knot* was a knot made in the leathers or harneſs of the chariot of Gordius, king of Phrygia, and father of Midas; ſo very intricate, that there was no finding where it began or ended.

The inhabitants had a tradition, that the oracle had declared, that he ſhould be maſter of Aſia who could untie this knot. Alexander having undertaken it, and ſeeing that, if he ſhould not be able to effect it, it would be deemed an ill augury, and prove a check in the way of his conqueſts, cut it aſunder with his ſword; and thus, ſays Quintus Curtius, either accompliſhed the oracle, or eluded it. But Ariſtobulus gives a different account of this matter. See Arrian, lib. ii. cap. 20. and Plut. in Vit. Alex.

Some will have the *phraſe* derived from Gordius, who tied the fatal knot; others from Gordium, a city in Phrygia, where the knot was made.

GORDONIA, *ſhrubby box*, in *Botany*, a genus of the *monadelphia polyandria* claſs. Mr. Miller has erroneouſly claſſed this elegant American evergreen-tree under the genus of *hibiſcus*, and Linnæus under that of *hypericum*; but Mr. Ellis has made it a diſtinct genus, under the name of *Gordonia*, in compliment to Mr. James Gordon, ſome time a diſtinguiſhed gardener and botaniſt in the neighbourhood of London. Its characters are theſe: the perianthium conſiſts of five concave, roundiſh, downy leaves, hairy on their edges; the flower is compoſed of five large, flatiſh, concave, inverted-oval petals, united at the baſe, which includes a round-ſhaped fleſhy ſubſtance, like a nectarium, ſurrounding the germen; the filaments of the ſtamina are numerous and linear, inſerted in the top of the tunnel-ſhaped tube, but equally diſtinct from each other; the antheræ are of an oval form and erect, having a cell on each ſide full of farina of a globular ſhape; the germen is oval and acuminated towards the top, where the ſtyle begins: the ſtyle is ſhort, and formed with five ſmall ridges on the ſides, which terminate in five acute ſtigmata, diſpoſed horizontally in a radiated form; on the upper part of each of theſe is a longitudinal cavity, covered with down: the capſule, which is egg-ſhaped and acuminated at the top, is of a woody conſiſtence, and opens, when ripe, into five valves with five cells; each of which contains two ſeeds that are kidney-ſhaped, and winged obliquely on one ſide. Phil. Tranſ. vol. lx. N° 44. p. 328, &c.

GORE, in *Heraldry*, denotes one of the regular ABATEMENTS, uſed, according to Guillim, to denote a coward. It conſiſts of two arches or curve lines, drawn, one from the ſiniſter chief, the other from the ſiniſter baſe, and meeting in an acute angle in the middle of the eſſe-point, as repreſented in *Tab. II. Heraldry, fig. 67.*

GOREING, or GORING, is ſaid of a ſail when cut ſlanting, ſo that it is broader at the clew than at the earing, as all top-ſails and top-gallant-ſails are.

GOREL, a name or title given to the prince of Georgia. The *gorel* is always a Mahometan. The ſophy of Perſia obliges him to obſerve the religion of the Alcoran, in order to preſerve the dignity of *gorel* in his family.

GORGE, in *Falconry*, is the uppermoſt bag or ſtomach of a hawk or falcon, being that which receives the food the firſt.

The *gorge*, *ingluvies*, is the ſame, in birds of prey, with what we call the *craw* or *crop*. When the bird is *fed*, he is ſaid to be *gorged*.

GORGE, *in Architecture*, denotes a ſort of concave moulding, wider but not ſo deep as a SCOTIA; uſed chiefly in friezes, chambranles, &c. See *Tab. Archit. fig. 6 and 8.*

GORGE *of a chimney* is that part between the chambranle and the crowning of the mantle. Of this there are divers forms; ſtraight, perpendicular, in form of a bell, &c.

GORGE is ſometimes alſo uſed for a moulding that is concave in the upper part, and convex at bottom; more properly called OGEE and CYMATIUM.

GORGE is alſo uſed for the neck of a column; more properly called *colarin* and GORGERIN.

GORGE, in *Fortification*, the entrance of a BASTION, or of a RAVELIN or other OUT-*work*.

The GORGE *of a baſtion* is what remains of the ſides of the polygon of a place, after retrenching the curtins; in which caſe it makes an angle in the centre of the baſtion. Such is A H D, *Tab. Fortif. fig. 1.*

In flat baſtions the *gorge* is a right line on the curtin, touching between the two flanks.

GORGE *of a half-moon* or *ravelin*, is the space between the two ends of their faces next the place.

Gorge of the other out-works is the interval betwixt their sides next the ditch.

All the *gorges* are to be made destitute of parapets; otherwise the besiegers, having taken possession of a work, might make use thereof to defend themselves from the shot of the place: so that they are only fortified with palisadoes, to prevent a surprize.

GORGE, *Half the* GORGE, DEMI GORGE, that part of the polygon between the flank and the centre of the bastion; as A H.

GORGED, in *Heraldry*, is when a crown, coronet, or the like thing, is borne about the neck of a lion, a swan, &c. In that case they say, the lion or cygnet is *gorged* with a ducal coronet, &c.

GORGED is also used when the gorge or neck of a peacock, swan, or the like bird, is of a different colour or metal from the rest.

GORGED, among *Farriers*, &c. signifies as much as swelled. In which sense they say, the legs of a horse are *gorged*; the pastern-joint is *gorged*; you must walk him out, to *disgorge* his shoulder.

GORGERIN, a part of the ancient armour; being that which covered the throat or neck of a person armed at all points.

GORGERIN, or GORGE, in *Architecture*, the little freeze, in the Doric capital, between the astragal, at the top of the shaft of the column, and the annulets. See *Tab. Archit. fig.* 25. N° 18.

Some call it *collarino*. Vitruvius gives it the name *hypotrachelium*.

GORGET, in *Military affairs*, a piece of brass or silver, worn by the officers of foot upon their breasts when on duty. The *gorget* hangs round the neck by a ribband; they are sometimes gilded, and have commonly some device engraved on them; as the sovereign's, or even the colonel's coat of arms, creft or cypher.

GORGET, or GORGERET, in *Surgery*, is the name which the French give to the concave or cannulated CONDUCTOR, used in LITHOTOMY. See *Tab. III. Surgery, fig.* 30. In *fig.* 31. there is exhibited the *gorget*, as it has been improved by Mr. Le Cat, and which he calls *gorget stramboeidiforme*. A is a ring for passing the middle finger of a right hand, which grasps the handle G. B is another ring, which is slid by the fore-finger towards *d*, to push the blade *a b* out of the groove EF. The figure represents the instrument in the state in which it is at the very instant when the incision is made into the neck of the bladder. The same fore-finger draws the piece B back towards A, when the operator intends to make the blades return into the groove F; where they lie hid, while he introduces the instrument from *d* to *e*, in order to secure the pieces *a, b, c, d, e*, in their proper situation. The pins which bind the hinges *a, b, c*, must not be in the centre of the pieces, but as they are expressed in the figure: where *b* is pretty near the outer edge, and the other two, *a, c*, on the opposite side; so that, when the ring B is thrust forward, the hinge *b* may bend and issue out of the groove F, by making the angle *a b*. Phil. Trans. vol. xlvi. p. 100.

GORGONIA, in *Natural History*, a name given by some writers to CORAL, on occasion of its supposed change from a soft substance to an absolute stone, on being brought out of the water into the air; but this is known now to be a fabulous opinion, coral being as hard while growing to the rocks, as when it has been ever so long out of the sea.

The *gorgoniæ* are of a genus of ZOOPHYTES, which formerly were called *ceratophyta*, and are known in English by the names of sea-fans, sea-feathers, and sea-whips. Dr. Linnæus and Dr. Pallas consider them as of a mixed nature in their growth, between animals and vegetables; but Mr. Ellis has clearly proved, that they are true animals of the POLYPE kind, growing up in a branched form resembling a shrub, and in no part vegetable. They differ from the fresh water polype in many of its qualities, and particularly in producing from its own substance a hard and solid support, serving many of the purposes of the bone in other animals. This is formed by a concreting juice thrown out from a peculiar set of longitudinal parallel tubes, running along the internal surface of the fleshy part: in the coats of these tubes are a number of small orifices, through which the coarse liquor exudes, and, concreting, forms the layers of that hard part of the annular circles, which some, judging from the consistence rather than the texture, have erroneously denominated wood. The surface of the *gorgonia* is composed of a kind of scales, so well adapted to each other as to serve for defence from external injuries: and the flesh, or, as some have called it, the bark or cortex, consists of proper muscles and tendons for extending the openings of their cells; for sending forth from thence their polype suckers in search of food; and for drawing them in suddenly, and contracting the sphincter muscles of these flatry cells, in order to secure these tender parts from danger; and also of proper secretory ducts, to furnish and deposit the osseous matter that forms the stem and branches as well as the base of the bone. Mr. Ellis affirms, that there are ovaria in these animals, and thinks it very probable, that many of them are viviparous. Phil. Transact. vol. lxvi. part 1. art. 1. See CORALLINE.

GORGONEI *fontes*, an affected term used by some of the writers in chemistry, to express those springs or waters which turn things into stone. We have several springs in England, which cover over things with a stony matter, without introducing it into their inner structure; but there are very few certain instances of waters, which at this day absolutely petrify wood, that is, fill its pores with true stony matter. The famous water of Lough Neagh, in Ireland, is much disputed by some as to its having this quality, and many fruitless experiments have been made in attempting to prove that it has.

GORGONEUM, Γοργόνειον, in *Antiquity*, a kind of masque used on the ancient theatre to represent hideous and frightful figures, in imitation of the GORGONS. Mem. Acad. Inscript. tome v. p. 184.

GORGONIUM, in *Botany*, a name given by some authors to the common eryngium or eryngo, the roots of which we use candied.

GORGONS, in *Antiquity* and *Mythology*. Authors are not agreed in the account they give of the *Gorgons*. The poets represent them as three sisters, whose names were Stheno, Euryale, and Medusa; the latter of whom was mortal, and having been deflowered by Neptune, was killed by Perseus; the two former were subject neither to age nor death. They are described with wings on their shoulders, with serpents round their heads, their hands were of brass, and their teeth of a prodigious size, so that they were objects of terror to mankind. After the death of Medusa, her sisters, according to Virgil, were appointed to keep the gate of the palace of Pluto.

Multaque præterea variarum monstra ferarum—
GORGONES, *Harpiæque*——

Diodorus Siculus will have the *Gorgons* and Amazons to have been two warlike nations of women, who inhabited that part of Libya which lay on the lake Tritonidis. The extermination of these female nations was not effected till Hercules undertook and performed it.

Pausanias says, the *Gorgons* were the daughters of Phorbas, after whose death Medusa, his daughter, reigned over the people dwelling near the lake Tritonidis. The queen was passionately fond of hunting and war, so that she laid the neighbouring countries quite waste. At last, Perseus having made war on them, and killed the queen herself, when he came to take a view of the field of battle, found the queen's corpse so extremely beautiful, that he ordered her head to be cut off, which he carried with him to show his countrymen, the Greeks, who could not behold it without being struck with astonishment.

Others represent them as a kind of monstrous women, covered with hair, who lived in woods and forests. Others, again, make them animals, resembling wild sheep, whose eyes had a poisonous and fatal influence. For a farther account of them, see Mem. Acad. Inscript. vol. iv. p. 72. seq. See MEDUSA *caput*.

GORSE. See FURZE.

GOSHAWK, in *Ornithology*, the English name for the *accipiter* or *falco palumbarius*, a very large hawk, which preys on pheasants, geese, and hares, and is remarkable for the shortness of its wings.

It is larger than the common buzzard, but of a longer and more elegant form. The bill is blue towards the base, black at the tip; the cere is a yellowish green; over each eye is a white line, and on the side of the neck a bed of broken white; the head, hind part of the neck, back, and wings, are of a deep brown colour; the breast and belly white, beautifully marked with numerous transverse bars of black and white; the tail is long, of a brownish ash-colour, marked with four or five dusky bars placed remote from each other. The legs are yellow; the claw of the back and that of the inner toe very large and strong. This bird breeds in Scotland, and builds its nest in trees. Roy and Pennant.

GOSLINGS, the name given to young geese.

GOSPEL, a history of the life, actions, death, resurrection, ascension, and doctrine of Jesus Christ.

The word is Saxon, and of the same import with the Latin term *evangelium*, or the Greek εὐαγγέλιον, which signifies *glad tidings*, or *good news*; the history of our Saviour being the best history ever published to mankind. This history is contained in the writings of St. MATTHEW,

THEW, St. MARK, St. LUKE, and St. JOHN; who from thence are called Evangelists. The Christian church never acknowledged any more than these four Gospels as canonical; notwithstanding which, several apocryphal gospels are handed down to us, and others are entirely lost.

GOSSAMER is the name of a fine filmy substance, like cobwebs, which is seen to float in the air, in clear days in autumn, and is more observable in stubble-fields, and upon furze and other low bushes. This is probably formed by the flying spider, which, in traversing the air for food, shoots out these threads from its anus, which are borne down by the dew, &c.

GOSSAMPINUS, a name given by Pliny and the ancients to a tree growing in the East Indies, which produced a sort of cotton, the threads of which were too short to be spun or carded; so that it served only for the stuffings of beds and the like, for which it was very proper, being very light and soft. It was in some esteem in medicine also, to recall the heat and spirits into parts to which it was applied. It is called by Pliny *arbor lanigera*, *the wool tree*, and had its ancient name from the words *gossypium*, *cotton*, and *pinus*, *the pine-tree*, being somewhat like the pine in external appearance, yet bearing a sort of cotton.

GOSSYPIUM. See COTTON.

GOTHIC, or GOTHICK, something that has a relation to the Goths, an ancient people, originally inhabiting that part of Sweden called Gothland; whence they spread themselves over Greece, Dalmatia, Bulgaria, Italy, Spain, &c.

We say, the *Gothic* manner; *Gothic* ignorance; the tyrant Maximian was of *Gothic* race.

It has been a general opinion, strenuously maintained by Cluverius and Pelloutier, and adopted by Mallet in his Northern Antiquities, that the *Gothic* and Celtic nations were the same: but the ingenious English translator of Mr. Mallet's work has produced a variety of testimonies from ancient authors to prove, that the Celtic and Teutonic or *Gothic* nations were, *ab origine*, distinct, and that they differed considerably in person, manners, laws, religion, and language. The former were the ancestors of the Gauls, Britons, and Irish; and the Germans, Saxons, and Scandinavians derived their origin from the latter. The Celtic tribes were probably the first that travelled westward; and the *Goths*, or Getæ of the ancients, who emigrated at different times from the eastern countries after them, might borrow some of their opinions and practices, which will account for the resemblance that has been observed between them, without admitting that they were descended from them, or that they should be considered as the same people. In the same way we may account for those reliques both of Celtic and *Gothic* superstitions which are discernible in Gaul and Britain and many other countries, the inhabitants of which derive their descent equally from the Celts and *Goths*, who were at different times masters of these kingdoms, and whose descendants are now blended together: thus, the first inhabitants of Gaul and Britain being of Celtic race, followed the Druidical superstition. The ancient Germans, Scandinavians, &c. being of *Gothic* race, professed that system of polytheism which was afterwards delivered in the EDDA: and the Franks and Saxons, who afterwards settled in Gaul and Britain, being of *Gothic* race, introduced the polytheism of their own nation, which was in general the same that prevailed among all the other *Gothic* or Teutonic people. With regard to the *Gothic* and Celtic languages, they are radically different from each other: and from these two mother-tongues the following particular languages are severally derived: from the *Gothic* are derived the old Saxon or Anglo-Saxon, the Francic or Franco-theotisc, and the Cimbric or old Icelandic; of the old Saxon are formed the English, the broad or Lowland Scotch, the Belgic or Low Dutch, and the Frisic or Friezeland tongue; from the Francic proceed the German or High Dutch, the German of Swabia, and the Swiss; and the Cimbric is the immediate source of the Icelandic, Norwegian or Norse, Danish, and Swedish. From the Celtic language are derived the ancient Gaulish, the ancient British, from which proceeded the Welsh, Armorican or Bas-Bretagne, and Cornish; and the ancient Irish, from which sprung the Irish, Erse or Highland Scotch, and the Manks or language of the Isle of Man. See the preface and notes to the English edition of Mallet's Northern Antiquities, 1770. See TEUTONIC.

GOTHIC *Bible*. See BIBLE.

The *Gothic* version of the four Gospels, first printed at Dort in 1665, was published at Oxford in 1750, by Mr. Lye: this edition was designed and prepared by Benzelius, archbishop of Upsal, with a Latin translation and notes, in which the editor introduced some small variations, and added a *Gothic* grammar. The ancient manuscript of the *Gothic* version is preserved in the library of the university of Upsal, in Sweden, under the name of the *Codex Argenteus*, or *Silver book*, because the letters, which seem to have been stamped on the vellum leaves with hot metal types, are of Silver, except the initials, which are gold. Another fragment of this curious version, containing part of the Epistle to the Romans, has been since discovered in the library at Wolfenbuttle, and published a few years ago in a splendid volume in quarto, by the Rev. F. A. Knittell, archdeacon of Wolfenbuttle.

GOTHIC *character* or *writing*, is a character or manner of writing which, in the main, is the same with the Roman, only that it is very full of angles, turns and bendings, especially at the beginning and ending of each letter.

The manuscripts in *Gothic* characters are not very ancient. Ulphilas, bishop of the Goths, was the first inventor of the *Gothic* characters, and the first that translated the Bible into the *Gothic* tongue.

The letters used in the *Gothic* gospels are twenty-five in number, and formed, with slight variations, from the capitals of the Greek and Latin alphabet.

The Runic characters are also frequently called *Gothic* characters. See Mallebillon, De Re Diplomat. lib. 1. cap. 2. But they who take the *Gothic* characters to be the same with the Runic, are mistaken; as is shewn by Ol. Wormius, Junius in his preface to the Gospels wrote in *Gothic* letters, and Dr. Hicks on the Runic Tongue.

GOTHIC *architecture* is that which derives from the proportions, characters, &c. of the antiques.

The *Gothic* architecture is frequently very solid, heavy, and massive; and sometimes, on the contrary, exceedingly light, delicate and rich. An abundance of little whimsical ornaments are its most usual characters.

Authors distinguish two kinds of *Gothic* architecture; the one *ancient*, the other *modern*. The *ancient* is that which the Goths brought with them from the North, in the fifth century: the edifices built in this manner were exceedingly massive, heavy, and gothic. The characteristic marks of this style are those: the walls are very thick, generally without buttresses; the arches, both within and without, as well as those over the doors and windows, semi-circular, and supported by very solid or rather clumsy columns, with a kind of regular base and capital: in short, plainness and solidity constitute the striking feature of this method of building. However, the architects of those days, when this style prevailed, did not wholly neglect ornaments.

Those of the *modern Gothic*, or, as it should rather be called, the ARABESC, was introduced about the tenth century, and ran into the other extreme, being light, delicate, and rich to a fault; witness Westminster-abbey, the cathedral of Litchfield, the cross of Coventry, &c.

The last kind continued long in use, especially in Italy; viz. from the thirteenth century to the restauration of the antique building in the fifteenth. All the ancient cathedrals are in this kind.

The inventors of the *Gothic* architecture thought, no doubt, they had far surpassed the Greek architects: a Greek building has not a single ornament but what adds a beauty to the whole: the parts necessary to sustain or shelter it, as the columns, cornices, &c. derive all their beauty from their proportions; every thing is simple, measured, and restrained to the use it is intended for; no daring out-of-the-way strokes; nothing quaint to impose on the eye; the proportions are so just, that nothing appears very grand of itself, though the whole be grand. On the contrary, in the *Gothic* architecture, we see huge vaults raised on slender pillars, which one would expect every minute to tumble down, though they will stand for many ages. Every thing is crammed with windows, roses, crosses, figures, &c.

The marks which constitute the character of modern *Gothic* or Saracenical architecture, are its numerous and prominent buttresses, its lofty spires and pinnacles, its large and ramified windows, its ornamental niches or canopies, its sculptured saints, the delicate lace-work of its fretted roofs, and the profusion of ornaments lavished indiscriminately over the whole building: but its peculiar distinguishing characteristics are, the small clustered pillars and pointed arches, formed by the segments of two intersecting circles; which arches, though last brought into use, are evidently of a more simple and obvious construction than the semi-circular arches. The first appearance of this style of building in our country was towards the latter end of the reign of Henry II. In the reign of Henry III. it seems to have gained a complete footing: the present cathedral church of Salisbury, which is entirely in this style, was begun early in this reign, and finished in the year 1258. From the reign of Henry VIII. or the close of that of Henry VII. the

Gothic architecture began to decline, and was soon after supplanted by a mixed style, wherein the Grecian and *Gothic* are blended together. The Roman or Grecian architecture did not prevail in England till the time of Inigo Jones; yet there were some earlier specimens of this style, particularly Somerset-house in the Strand, built in 1549, but lately pulled down, and rebuilt.

Most of the great buildings of queen Elizabeth's reign have a style peculiar to themselves; in which, though much of the old *Gothic* is retained, and great part of the new taste is adopted, yet neither predominates; while both, thus ill-timily blended, compose a fantastic species, hardly reducible to any class or name. One of its characteristics is, the affectation of large and lofty windows. See ARCHITECTURE.

GOTHIC *column* is any round pillar in a *Gothic* building, either too thick or too small for its height.

There are some found seventy-seven diameters high, without either diminution or swelling.

GOTHIC *medals*. See MEDAL.

GOTTORUGINE, in *Ichthyology*, the name of a small fish common in the Mediterranean, and brought to market at Rome, Venice, &c. It has no scales, but is soft and lubricous to the touch, large toward the head, and smaller toward the tail, and of a flatted shape. Its colour is mottled with olive-colour and a brownish red, disposed in lines running half-lengths, and parted by other lines of a pale blue. It is usually of about six or seven inches long. It has no swimming-bladder, and the anus is situated nearer the head than the tail. See ADONIS and FLYING-*fish*.

GOUANIA, in *Botany*, a genus of the *polygamia monoecia* class. This genus bears hermaphrodite and male flowers: the hermaphrodite have a calyx divided into five segments; no corolla; five antheræ; and a trifid style; the fruit is composed of three parts; the male resemble the former, but has neither germen nor stigma.

GOUD, or GAUD. See WELD.

GOVERNMENT, a quality or office which gives a man power or right to command or rule over a place, a city, a province, a kingdom, or the like, either supremely or by deputation.

Government is either *general* and supreme, as that of a whole kingdom, empire, sovereign state, &c. or *particular* and subordinate; which, again, is subdivided into *civil*, *military*, and *ecclesiastical*.

Our cities, corporations, and boroughs, are usually governed by mayors, with aldermen and common-councilmen.

GOVERNMENT is also used for the country, city, or place to which the power of governing or commanding is extended.

There are thirty-eight *governments* or provinces in France, independent of each other. Beside these, there is another division into *gouvernments*, called *grand gouvernments*, whereof there are twelve; viz. those of the Isle of France, Burgundy, Normandy, Britanny, Picardy, Dauphiny, &c. which are not proper provinces, commanded each by its separate governor, but rather so many classes of governors or *gouvernants*, contrived for the better and easier regulating the feasts, &c. of so many governors, bailiffs, provosts, &c. as were obliged to assist at the holding of the general estates.

GOVERNMENT, again, is used for the manner or form of *governing*, i. e. for the policy of a country, state, &c.

In this sense, *government* are divided into MONARCHIES, ARISTOCRACIES, and DEMOCRACIES.

The *government* of France is *monarchic*; that of Venice, *aristocratic*; and that of the United Provinces, *democratic*: the *government* of England is *mixt*; being monarchical, aristocratic, and democratic, all in one.

Civil *government* and society originate in the wants and fears of individuals, who, being naturally free, equal, and independent, associate together, either by express or tacit consent, for the mutual preservation of their lives, liberties, and estates, on this fundamental principle, that the whole should protect all its parts, and that every part should pay obedience to the will of the whole. However the several forms of *government*, that now obtain, accurately begun, there is and must be in all of them a supreme, irresistible, absolute, uncontrolled authority, in which the *jura summi imperii*, or the rights of sovereignty, reside; and this authority is placed in those hands, wherein, according to the opinion of the founders of such respective limitations expressly given, or collected from their mere apprehension, the qualities requisite for supremacy, viz. wisdom, goodness, and power, are the most likely to be found.

Individuals unite for mutual protection and benefit; and, therefore, the legislative and executive authority of *government*, originally derived from themselves, should be invariably directed to no other end but their safety and welfare; and that form of *government* is most eligible, which is best adapted to these purposes. Cicero declares himself of opinion, in his fragments De Rep. lib. ii. "*ego optimam constitutam rempublicam, quæ ex tribus generibus illis, regali, optimo & popolari, sit modice confusa.*" Of this kind is the British constitution, which lodges the executive power of the laws in a single person, and the legislature in three distinct powers, entirely independent of each other; viz. the king; the lords spiritual and temporal, forming an aristocratical assembly; and the house of commons, freely chosen by the people, which renders it a kind of democracy: and each branch of this aggregate body, actuated by different views, and attentive to different interests, is armed with a negative power, sufficient to repel any innovation which it shall think incumbent or dangerous. Nothing can endanger or hurt the constitutional *government* of Britain, but destroying the equilibrium of power between one branch of the legislature and the rest: for if ever it should happen that the independence of any one of the three should be lost, or that it should become subservient to the views of the other two, there would soon be an end of our constitution: the legislature would be changed from that which was originally set up by the general consent and fundamental act of the society; and such a change, however effected, is, according to Mr Locke, at once an entire dissolution of the bands of *government*, and the people are thereby reduced to a state of anarchy, with liberty to constitute to themselves a new legislative power. Locke on Government, book ii. chap. 19. Blackst. Com. vol. i. Introd. See LAW, LIBERTY, PARLIAMENT, &c.

GOVERNMENT, in *Grammar*, is understood of that construction of nouns and verbs, wherein they require some alteration to be made in others joined or construed with them.

Construction is divided into two parts; that of CONCORD, and that of *government*, called also REGIMEN.

GOVERNOR, an officer vested by a king, or sovereign prince, with the command and administration of a province, place, &c.

A *governor* represents the king; and not only commands the garrison, troops, &c. but the citizens, &c. A *governor* of a fortified place was anciently required to hold out three attacks, before he surrendered.

GOVERNOR is also frequently used for a president, or superintendant.

Thus we say, the *governor* of the bank; the *governor* and directors of the South-sea company; the *governor* of an hospital, &c.

GOVERNORS *of the chest at Chatham*, are officers appointed to take care of, and relieve the poor and maimed seamen belonging to the royal navy. Vide 22 and 23 Car. II.

GOUF. See GOLF.

GOUGE, an instrument used by divers artificers; being a sort of round, hollow chisel; serving to cut holes, chanels, grooves, &c. in wood, stone, &c.

GOUMA, in *Mineralogy*, the name given by the natives of the island of Samos, to the Samian earth, called *terra Samia* by the old writers.

GOURD, *Cucurbita*, in *Botany*, a genus of the *monoecia syngenesia* class. Its characters are these: it hath male and female flowers, which are bell-shaped, ashering to a bell-shaped empalement of one leaf, and composed of one petal, divided at the top into five parts, on the same plant; the male flowers have three stamina, which are connected at the extremity, but are distinct at their base; the female flowers have a large germen, which becomes a large fleshy fruit, having three soft membranaceous cells, which are distinct, including two rows of seeds, which are bordered. Miller reckons five species, and Linnæus six, one of which is the common pompion or PUMPION, and another the calabash or MELOCOTO.

Gourds are esteemed cooling and diuretic, are used in emulsions, and effected good in fevers, and all disorders arising from the acrimony of the blood or humours. Emulsions of these, and the other cold seeds, are anodyne, and are generally used to take off irregular effusions by blisters: but these prepared from sweet almonds are more universally preferred.

GOURD-*tree*. See CALOCYNTHIS.

GOURD, *Indian*, &c. See CALABASH *tree*.

GOURD, *sea*. See RADDA.

GOURD-*worm*, the English name of a species of worm found in the intestines of several animals. It has this name from its resembling the seed of the *gourd* in figure.

GOURDY *legs of horses*. See GREASE.

GOURY *pigeon*, in *Natural History*, a name given by the people of the East Indies to a kind of pigeon of a deep yellow colour, veined with red in several places, and in some with white. It is found principally at the bottom of mountains. They calcine it several times, and afterwards

afterwards give it internally in intermitting fevers, and *ufe* it externally in ointments for the itch.

GOUST, *Gout*, a French term, for what the Italians call *guſto*, and we TASTE.

GOUT, *Arthritis*, in *Medicine*, a painful diſeaſe, occaſioned by a flux of ſharp humour upon the joints of the body.

Some phyſicians define the *gout*, an inflammation, ſwelling, and painfulneſs of the joints. Its origin is uſually attributed to wine, venery, gluttony, idleneſs, and grief, or any violent perturbation of the mind. Intemperance and indolence are the principal cauſes of the *gout*; however, a paroxyſm in thoſe who are ſubject to it may be occaſioned by unuſual ſtudy, too free a uſe of acid liquors, night-watching, vexation and uneaſineſs, an obſtruction or defect of any of the cuſtomary diſcharges, as the menſes, ſweating of the feet, perſpiration, &c. The predipoſing cauſe is the magnitude of the lacteals, and the ſtraightneſs of the ſmall veſſels, particularly the perſpiratory. The groſs tartarine *gouty* particles, ſays *Dr.* Hales, are moſt apt to ſtrike and cauſe inflammatory obſtructions in the extremities of the body, as in the feet and hands, where the progreſſive force of the blood is the leaſt, as being fartheſt from the heart. And when theſe humours fix in the trunk of the body, they are more apt to ſettle in the ſtomach than in the guts; becauſe in the former they have as much greater a length of capillary veſſels to retard the motion of the blood, as half the circumference of the ſtomach is greater than that of the guts; for the arteries of the ſtomach do not enter its coats on one ſide only, as thoſe of the guts do, but it is ſupplied with blood by arteries which enter, ſome on the upper hand, ſome on its lower ſide; their converging branches inoculating about the middle of the tunic. Hales's Statical Eſſays, vol. ii. p. 108. ed. 1769.

The *gout* is ſuppoſed to ariſe from two cauſes; a redundancy of humours, and a weakneſs of the joints. Its proper ſeat is in the limbs, not in the trunk of the body; in the latter caſe it frequently proves mortally not in the former.

Muſgrave makes the apoplexy a *gout*, becauſe it ariſes from the abundance of pituita, or phlegm. According as this redundant pituita throws itſelf on the lungs, the liver, or any other part, it makes, according to him, an apoplectic *gout*, a *gout* of the liver, of the lungs, of the ſpleen, &c. The *gout* may be conſidered as a painful, periodical, and critical paroxyſm, tending to free the body of an offenſive or corrobve matter, by throwing it upon the extremities, breathing it out inſenſibly, or comminuting it ſo as to render it harmleſs, or capable of circulating freely along with the juices; till by collecting again, gradually increaſing, or ſeparating from the blood, it cauſes another paroxyſm.

As this diſeaſe receives different appellations, according to the places it affects, the following diſtinctions will be found neceſſary, to prevent confuſion on this head.

Arthritis is a word very differently underſtood by different authors, ſome expreſſing by it only what we call the *gout*; others making it the general name of that and many other diſeaſes of the ſame nature and origin, and diſtinguiſhing that particular ſpecies of it which we call the *gout*, by the term *podagra*. Stahl, and from him Junker, define the *arthritis* to be a ſpaſtic affection of the joints in any part of the body, affecting the patient with a vehement and laſting pain, and never coming to that ſalutary end, which nature formed to intend by her motions in it. The *podagra* in particular is thus defined to be a ſpaſtic and painful affection of the foot, taking its origin from a congeſtion of blood, which ſhould have been voided by the hæmorrhoidal veſſels, and which finding no means of evacuation there, becomes very painful in its emotions, and growing into a habit afterwards, recurs on any ſlight occaſion.

When the *arthritis* is taken in its general ſenſe, it comprehends ſeveral diſeaſes ſubdiſtinguiſhed by their ſeveral ſpecific names, as the hemicrania, the ſpurious pleuriſy, the ſciatica, the chiragra, the gonagra, and finally the podagra, or *gout* in the feet.

Some authors take the word *arthritis* in a more ſpecific ſenſe than this, and yet diſtinguiſh it ſufficiently from the *podagra*; theſe expreſs by it thoſe ſpaſtic affections which happen in the upper limbs and parts of the body; it is then made of the ſame genus with the *podagra*, and diſtinguiſhed from it, as one ſpecies from another, by the following particulars.

The *arthritis* affects young perſons, the *podagra* thoſe more advanced in years. The *arthritis* is naturally the firſt of theſe two diſeaſes in perſons who have them both; and as people afflicted with it grow into years, it very naturally degenerates into a *podagra*. This is a diſtinction of ſome very judicious authors; yet in reality the ſeveral appearances of the *arthritis*, as taken in its moſt general ſenſe, differ no otherwiſe than as to the places they affect, and the times at which they happen; they all agree in their eſſential conditions and general cauſes. The true *arthritis* is however to be carefully diſtinguiſhed from what is called the *arthritis vaga*, wandering, ſimple, or ſcorbutic *arthritis*. This very ſuddenly flies from one part of the body to another, and changes places from the feet to the thorax, from the hips to the hips and ſo on. Junker's Conſp. Med. p. 615. The rheumatiſm and *arthritis* are diſeaſes alſo not greatly different from, but properly ſubordinate to one another; and as light *arthritis* is very often called a fit of the rheumatiſm. The rheumatiſm is no other than a ſtagnation of the maſs of blood about particular parts of the body, taking its origin from a copious congeſtion of the blood particularly directed by nature to that part. The rheumatiſm has its ſeat in the muſcular parts of the body, *arthritis* principally affects the joints of the ſeveral limbs. The rheumatiſm naturally precedes the *gout*, and very often degenerates into it; it is even certain that the rheumatiſm and *arthritis* often are complicated together. Simple congeſtions and commotions of the blood differ extremely from the *arthritis*; firſt in regard to their effects, for they uſually terminate in an eruption of the blood by ſome means, but the *arthritis* never arrives at that end.

Secondly in their duration, for they are uſually terminated ſome way within a very ſhort period; but this diſeaſe is of very long and terrible duration. They differ, thirdly, in regard to the parts they affect: the ſimple congeſtions affect the internal parts and the blood-veſſels; but the *arthritis* affects the external, and the muſcular fibres. Finally, they differ not leſs in regard to the event; for the ſimple congeſtions bring on inflammations and ulcerations, but the *arthritis* contractions and extenſions of the limbs.

The ſigns of the ſciatica are a vehement and excruciating pain in the hip, which remains a long time, and is felt principally in the tendons, and in the junctures of the bones. This ſpaſm ſo violently affects the muſcles of the whole ſide, that the patient is compelled to walk in a crooked poſture.

The other *arthritic* complaints, as the hemicrania, &c. are deſcribed under their ſeveral heads, and the general method of cure is the ſame in all of them.

The *gout* is either *regular* or *irregular*. *Regular*, when it appears to be ſeated in the extremities of the body, when it chiefly and immediately affects the tendons, nerves, membranes, and ligaments of the body, about the joints, returns at ſtated periods, and with a gradual increaſe and decline of the ſymptoms. *Irregular*, when the paroxyſms are frequent, and uncertain; when the ſymptoms vary, or happen promiſcuouſly, and the diſeaſe appears to be ſeated in the internal parts of the body; as the ſtomach, brain, &c. leaving the extreme parts, as the hands, feet, &c. free from pain. According as different parts are affected by this diſtemper, it goes by ſeveral diſtinct names: when it ſeizes the feet, it is called PODAGRA; when the knees, GONAGRA; when the hands, CHIRAGRA; and when the hip-joint, SCIATICA.

Sometimes it attacks the whole body at the ſame time, and then it is called the *general* or *univerſal gout*.

The immediate cauſe of the *gout* appears to be an alkaline, or acrimonious matter in the blood; which being ſeparated from it at particular times, falls upon the joints, but moſt frequently upon the feet and hands; which, if it be repelled, or if the blood be overcharged therewith, ſo that a criſis cannot be procured in the extremities (as generally happens in old age), it falls upon the nobler parts, and then produces the irregular *gout*: but it is the tunica cellularis of the affected parts, that is the immediate ſeat of the diſeaſe.

Dr. Stevens endeavours to prove the *gouty* humours to be rather of an alkaline than acid nature.

Dr. Cajetanus Tucconus tried many experiments with the mucilage of the joints of brutes, and of men, both ſound and *gouty*, in order to diſcover whether the *gouty* matter is acid or alkaline, and concludes, that its matter is ſometimes of the one, and ſometimes of the other nature. If the *gout* produces no *tophi*, or knots, as does it very ſlowly, and eſpecially if it is attended with redundatous ſwellings, he pronounces it to depend on an alkaline humours, but if the knots are large, and quickly formed, it is owing to an acid.

Dr. Hunter thinks that the oſſeous matter is ſeparated by ſmall arteries, and thrown upon the membranes or cartilages, and that there is more or leſs ſeparated as the one tunic is greater or leſs; and that in the *gout* there is a redundancy of bony matter, which probably forms the chalk ſtones.

Dr. Cheyne ſays, that the chief reaſon why the *gouty* matter

matter generally fixes on the joints is the preſſure there from the heads of the bones, which leſſens the capacity of the ſmall veſſels; to which may be added the ſmallneſs of the glands in the joints, and the natural coldneſs of theſe parts, occaſioned by the diſtance from the heart. The earthy particles, whoſe acrimony occaſions the *gout*, are conveyed into the *tunica cellularis* of the ligaments, tendons, &c. where the veſicles are leſs than in the bellies of the muſcles and fleſhy ſubſtances, and retained in them; and as they are more or leſs acrimonious, produce greater or leſs heat, and cauſe that inflammatory appearance and intolerable pain, which accompany this diſorder; but the parts affected ſoon loſing their ſenſibility, the ſpaſm abates, and the offending matter is again returned into the circulation, and diſcharged out of the body through the pores.

It is obſerved, that women, children, and young men, are ſeldom troubled with the *gout*, unleſs it be hereditary; and that it rarely attacks before the patient is thirty-five or forty years old, and ſometimes not till the decline of life; that the corpulent are more ſubject to it than thoſe who are ſpare and lean; that the pain increaſes towards night, and decreaſes towards the morning; that the longer the intervals between the paroxyſms, the more ſevere they proove, and the longer they generally continue. The diſeaſe uſually returns twice a year; viz. in the ſpring and autumn; and, in the latter, the paroxyſm is ſometimes two or three months before it comes to a period; though its duration is, at other times, not above three or four weeks.

Theſe are called *cardinal paroxyſms*, to diſtinguiſh them from others of leſs duration, which happen between the ſpring and autumn. The more high-coloured the urine, and the leſs ſediment it depoſits, the farther is the diſeaſe from the ſtate of *concoction*, as it is termed. According to the violence and continuance of the fever, the paroxyſm proves more or leſs ſevere.

In conſtitutions much broken or ſhattered with the *gout*, there are uſually ſtony or chalky concretions formed in the joints of the fingers, or toes, and thence tranſlated to the viſcera; which caſe is often attended with irregular, frequent, and ſhort paroxyſms, in the extremities; in the decline of life, when the uſual fits do not happen, or if the gouty matter be ſuddenly repelled from the extremities by an improper regimen, or medicines, it uſually ſeizes the internal parts, and frequently the ſtomach, head, inteſtines, &c. cauſing want of appetite, reaching to vomit, indigeſtion, a cachexia, the jaundice, aſthma, diarrhœa; and, at laſt, ſo obſtructs the fine capillary, nervous tubes (eſpecially thoſe of the ſtomach and brain) as, poſſibly, to hinder the flux of the animal ſpirits; upon which death ſuddenly enſues.

Sydenham gives us an accurate hiſtory of a regular fit of the *gout* in the feet: it begins towards the cloſe of January, or beginning of February, without the leaſt previous notice; except, perhaps, a reſtleſſneſs, or ſleepineſs, for ſome weeks before-hand; with a ſort of windy intumeſcence, a heavineſs of the body, and a dejection of ſpirits, which continually increaſe, till at laſt a paroxyſm breaks out; being preceded, ſome days, with a ſort of torpor, and a ſenſible deſcent of the flatulencies through the fleſh of the thighs, with ſome ſpaſmodic ſymptoms. The day before the paroxyſm, the patient's appetite is very ſtrong, and there is a ſlight pain in paſſing the urine; an hour or two after midnight he is waked by a pain, commonly in his great toe, ſometimes in the heel, ancle, or the calf of the leg, not unlike the pain felt upon a diſlocation of the ſaid bones; with a ſenſe as if water was ſprinkled on the part affected. This is ſucceeded by a chillneſs, and ſome approach to a fever: the pain, in the mean time, which at firſt was more remiſs, gradually increaſes; and in proportion to this the chillneſs abates. By night it is arrived at its height, and ſettled about the ligaments of the bones of the tarſus and metatarſus; where it ſometimes reſembles a violent tenſion, and ſometimes a laceration of theſe ligaments; ſometimes the biting or gnawing of a dog, or a ſqueezing, or exacerbation. Then for the part affected has ſuch an exquiſite ſenſe, that it cannot bear the weight of the linen, nor even the ſtirring of the room occaſioned by a perſon's ſtepping. Hence, a thouſand vain endeavours to get eaſe, by changing the poſture of the body, the poſition of the foot, &c. till about two or three o'clock in the morning (the ſpace of nychthemeron from its acceſs) when a remiſſion is firſt perceived; the morbid matter being by this time tolerably digeſted, or even diſſipated. The patient finds his pains much abated, but the part inflamed, ſwelled, and covered with a little moiſture. Towards morning he drops aſleep, and generally falls into a gentle breathing ſweat. A few days after this the other foot often undergoes the ſame fate; ſometimes both are attacked from the firſt. From the time it has ſeized on both legs, the ſymptoms become more irregular and precarious, both as to the time of invaſion, and the duration thereof. But this ſtill holds, that the pain recruits in the night, and remits again in the morning. A ſeries of theſe little, alternate acceſſes, &c. conſtitutes a fit of the *gout*, which holds longer or leſs according to the age and ſtrength of the patient, the ſeaſon of the year, and the diſpoſition of his body to the diſeaſe. The paroxyſms, however, grow milder every day, till at length the diſeaſe is carried off by perſpiration, urine, and the other evacuations. In ſtrong people, and thoſe who have had it often, fourteen days are a moderate fit: in old people, and thoſe long uſed to it, it will hold two months; though the tenderneſs and ſwelling in ſevere fits will ſometimes remain longer, and cauſe an uneaſineſs upon motion; and any violent exerciſe will bring it on again. For the firſt fourteen days the patient is uſually coſtive; a loſs of appetite, a chillneſs towards evening, and a heavineſs and uneaſineſs even of the parts not affected, attend the whole paroxyſm. As it goes off, he is ſeized with an inſufferable itching, eſpecially between the fingers; a ſurfeit falls off, and his urine ſcale, as if he had drunk poiſon.

Such is the courſe of a regular *gout*; but when through improper treatment it is diſturbed, or prolonged, it ſeizes the hands, wriſts, elbows, knees, and ſeveral other parts; ſometimes diſtorting the fingers, and taking away their uſe; ſometimes generating ſtoniaceous concretions, or knots about the ligaments of the joints reſembling chalk, or exoſtoſes; ſometimes cauſing a whitiſh, inflammable tumor, almoſt as big as an egg, about the elbows, &c. See NODE, TOPHUS, &c.

It may be added, that when a perſon has laboured under the *gout* for many years, the pain is ſenſibly leſſened each paroxyſm, till at length it becomes rather an uneaſineſs than a pain; hence the reflection of the great Sydenham, *Dolor in hac morbi ſpecie ſymptoma eſt ſæpe ſæpius non malum.*

Method of cure. The *gout* is ranked among the number of incurable diſeaſes: in effect, we have no thorough and aſſured remedy yet diſcovered for it; thoſe that now obtain are little more than palliatives; they tend to aſſuage the pain, to diminiſh it for a time, but not to extirpate it. Bleeding, and purging, and diaphoretics, are to be uſed with great caution. Emetics, according to Pitcairn and Ettmuller, may do good in the beginning of the diſeaſe. But, upon the whole, nothing, in Sydenham's opinion, proves of more ſervice than digeſtives, or medicines which ſtrengthen the ſtomach, and promote digeſtion: as, angelica root, cinn. campan. the theriac. Andromach. the Jeſuit's bark, and antiſcorbutics: theſe are chiefly to be adminiſtered in the intervals between the paroxyſms. Muſgrave, however, recommends, internally, repellants, and principally cardiacs; externally, emplaiſters of gum. caran. or exercoc. or cephalic with Burgundy pitch; or the green ſear-cloth, commonly called *bat-ſoſe*, &c. Yet Doleus affirms, that repellents do more harm than good; and gives us the following recipe, as more than equal to all others. ℞ Confect. hamech. ℥j. pulv. jalap. ℈ℌ. extract. trifol. fibrin. ℥ij. ſyſarg. aur. ℈ij. ſapo antimon. ʒvj. ſaccharat. cinnab. ℥j. ol. olivar. q. f. cerat. e pis paremi. f. l. a. An emplaiſter to be laid on the joint affected, till the pain, and the morbid matter, be driven away.

According to ſome, the material cauſe, which is a plethoric habit, is to be removed by bleeding at proper times, and by applying leeches to the hæmorrhoidal veins to promote a diſcharge that way; and in perſons of a moiſt habit, cupping is very proper. After this the crudities of the primæ viæ, eſpecially ſuch as are of a bilious nature, are to be abſterged, and gently carried off, as they always are the occaſion of all ſpaſtic pains being greatly exaſperated. The digeſtive ſalts, ſuch as *tartarum vitriolatum, arcanum duplicatum*, and the like, are very good abſtergents; and the proper method of evacuating the matter is by gentle laxatives, ſuch as purging draughts of ſenna and rhubarb, with a little ſoluble tartar. Glauber's ſalt, or the common purging ſalt, called Epſom ſalt, ſucceeds alſo very well; and great ſervice is done by the medicated wines, impregnated with the abſtergent, diuretic, and purging ingredients. A cleaneſs or uneaſineſs in the ſtomach muſt be removed by cardous or camomile tea, or by a little ſperacetonic. Vomits promote perſpiration; and in the circumſtance now mentioned, no danger need be apprehended. The violent emotions of the blood, and its ſulphureo-ſaline acrid quality, are to be attempered, and the rigors of the ſolids ſoftened and taken off. This is excellently done by nitrous medicines, with ſaline abſorbents; and in the more robuſt habits, ſometimes the ſtronger acids are neceſſary, after this nature is to be aſſiſted in making an equal and regular diſtribution of the humours. This is to be done in perſons of choleric habits,

habits, by means of the neutral salts, and the drinking large draughts of warm and different decoctions, such as a tea made of the herb veronica, which has of late years been celebrated as a medicine able to cure all the diseases of this kind alone. In other habits, the temperate alexipharmics are to be added on this occasion, such as decoctions of the woods of sassafras and guaiacum, and of china and sarsparilla, and pimpernel root.

Dr. Dewfon's fuccefs with the ufe of the tinct. guaiacol. and in occafional bleeding, deferves the attention of medical practitioners. He recommends it in the gout with or without fever, and in both the acute and chronical rheumatifm. His general mode of preferibing is as follows: R. Tinct. guaiac. vol. ʒiß. mucil. e gum. Arab. q. f. deinde adde gradatim aq. hordeat. ʒiß. fyr. balf. ʒß. m. fiat haufl. h. f. fumendi & repet. bis vel ter in die. See his Cafes in the Acute Rheumatism and Gout.

Finally, the vehement fpafmic and painful ftate of the parts is to be mitigated and taken off. To this purpofe fmall doſes of cinnabar, with the powder of earth-worms, are to be given, and with thefe the gentle diaphoretics: at the fame time thefe are given internally, there may be applied externally upon the wrift or wrifts a cataplafm mixed with tincture of lilies; the acid fpirit. diluted nitri, acet. and the fpirit of earth-worms. Tincture of caſtor may alſo be applied in this manner, and in fome cafes Venice foap diſſolved in fpirit of wine, or nitrous vegetable ointment. A decoct. with a large portion of valerian, has alſo been known to have good effects; and fome have applied with fuccefs the common foap plaſter; others prefer bags with the warm vegetables, fuch as the leaves of germander ground-pine, orpine, and pellitory, with the roots of pimpernel, angelica, and fuccaman's feet, and the feeds of anife and caraway feeds: others make thefe bags in a different way, ufing only oatmeal, elder-flowers, and laſtron, and fprinkling the bag over with camphorated fpirit of wine, or elſe dipping it all over in hot wine, and applying it immediately to the part. Some greatly recommend alſo the applying cheefe beaten to a fort of paſte to the part, covering it with a piece of a hair-ſieve; and many ſpeak highly of the effects of fuffumigations made by burning under the part the woods of faſſafras and guaiacum, with rofemary, with the woods of faſſafras and guaiacum, with rofemary and willow ſtumpers. The vapour of the decoctions of warm and aromatic herbs is alſo greatly recommended, and fome preſcribe gentle rubbing on the part with a ſoft brufh, or with flannels which have before been thoroughly impregnated with the fumes of the ſame mentioned dry fumigations. Thefe are the principal means of a cure; but there is no leſs judgment required in the time and manner of giving and applying them, than in the ſelecting them. In the time of the fit, it will be proper for the patient to take three or four times a day a powder prepared of nitre and tartar vitriolated, each half an ounce; crabs eyes levigated with lemon juice, three drachms; cinnabar, four ſcruples: theſe are to be all perfectly mixed together, and a ſcruple weighed out of every dofe, and after theſe it will be proper to take ſome gently diaphoretic draught; during the internal uſe of theſe, rags dipped in camphorated ſpirit of wine, impregnated with ſaffron, are to be applied to the parts, and to keep the bowels lax and ſoluble, a clyſter of the common emollient kind is to be given as occaſion ſhall require, with a ſmall quantity of nitre diſſolved in the decoction, and afterwards ſmall doſes of the common Epſom ſalt will be very proper for the keeping them in a due lax ſtate. After a fortnight's continuance in the uſe of the nitrous powders, it will be proper to take every day two or three doſes of a mixture of tincture of ſalt of tartar, and ſpirit of ſalammoniac, of which twenty-five drops are a doſe; and every night a ſmall doſe of the Barex pill may be taken, when the violence of the fit is abated. The gentle alexipharmics are to be taken without keeping up a hot regimen, and the frequent waſhing the feet in warm water, impregnated with an alkaline ſalt from the aſhes of vegetables, or otherwiſe, proves of the greateſt ſervice to compleat the carrying it off, and reſtore the parts to their natural tone. Junker's Conſp. Med. p. 623.

It is a general obſervation in all *arthritic* cafes, that all kinds of exercife, moderately promoted, leſſen the pains, and, on the contrary, that the ſuppreſſion of any of them render them much more violent and intenſe. Hence agitations are to be, as much as poſſible, avoided in the height of the fit; for though they give ſome eaſe for the preſent, they always increaſe the pain afterwards. However, when the patient is reſtleſs, thirty or forty drops of laudanum, more or leſs, according to the violence of the ſymptoms, taken at bed-time, will eaſe the pain, promote perſpiration, and forward the reſolution of the diſeaſe. The aſtringent fteel preparations, with the bole and other medicines of this claſs, ſuppreſs the excretions, conſtringe the viſcera, and ſometimes bring on dropſies. Volatile ſalts given imprudently, and in too large doſes, conſtringe the viſcera, and at the ſame time excite a violent emotion in the humours: hence they are often the occaſion of great miſchief; and it is very unhappy that the preſent practice is ſo free in the uſe of them in theſe cafes.

Among the external applications, thoſe which are aſtringent, cooling, faturnine, and the like, all give a temporary relief; but they are of very dangerous, and often fatal conſequences, as they bring on nodes, tophi, contractions of the parts in ſome cafes, and in all forcibly repel the matter to the internal parts, and bring on fatal ſymptoms, which no other medicines can relieve.

The acrid, hot, and nervine medicines uſed externally, ſuch as the chemical oils, and the natural balſams, all exaſperate the ſymptoms, and bring on intolerable pains and inflammations; for there is in theſe cafes, no weakneſs of the parts to be ſtrengthened by ſuch medicines, but a too great irritation and tenſion of them, which all medicines of this kind, by their acrid qualities, muſt neceſſarily add to.

Strong purges given in the time of the fit have often proved fatal, by drawing in the morbid matter to the internal parts; and bleedings in the time of the fits always make them more violent, ſubject the patient to more frequent returns, and bring on a neceſſity of repeating the bleeding every time before any medicines can take effect. But bleeding in the very beginning, or at the coming on of the fit, as alſo at its decline, has by real experience been found to be of the greateſt ſervice to the inflammatorial veins; as to the ſpaſtics, the cupping with deep ſcarification on the parts. By theſe means alone this diſeaſe has ſometimes been abſolutely cured, ſo as never to return again. Camphorated ſpirit of wine, and the tops of dry ingredients ſprinkled with it, are proper in all ſtages of the diſeaſe, and in all conditions.

A cerate of gallanum and camphor often gives immediate relief. This ſhould be applied after bleeding in the acceſs of the fit; and if it does not the effect in three hours time, it ſhould be taken off again. The ſoap-plaiſter, with a large portion of camphor, is often alſo found of great ſervice in the beginnings of theſe cafes. The waſhing the feet in warm water, if uſed juſt before the coming on of a fit of the *gout*, always makes it much more fierce; but if uſed afterwards, is often prover of ſervice. The proper time for it is in the decline of the fit.

As the moſt ſafe and efficacious method of diſcharging the *gouty* matter is by perſpiration, this ought to be promoted, eſpecially in the affected part. For this purpoſe the leg and foot ſhould be wraſt in ſoft flannel, *fay*, or wool. In Lancaſhire they conſider wool as a kind of ſpunge in the *gout*, and they wrap up a great quantity of it round the leg and foot, and cover it with a skin of ſoft dreſſed leather; the wool which they uſe is generally greaſed, and called or combed; and they ſeldom remove it till the fit is entirely gone off. The diet and drink ſhould be adapted to the conſtitution of the patient, and his uſual mode of living. If the patient be young and ſtrong, his diet ſhould be thin and cooling, and his drink of a diluting nature; but where the conſtitution is weak, and the patient has been accuſtomed to live high, he muſt keep nearly to his uſual diet, and frequently take a cup of ſtrong negus, or a glaſs of generous wine.

Wine whey, with the addition of a tea-ſpoonful of *ſal volatile oleoſum*, or ſpirits of hartſhorn, taken in the quantity of a cup twice a day, will promote perſpiration, without greatly heating the patient; and a tea-ſpoonful of the volatile tincture of guaiacum, in a large draught of warm wine-whey at bed-time, will promote perſpiration through the night. Bleed ſeems to be an unexceptionable conſtat in this diſeaſe. A warm and dry air is very ſalutary to a gouty patient; and daily exerciſe, during the intervals of the fit, friction with coarſe flannel, the ſleſh-brufh, &c. and regular diet, are very conducive to that due and conſtant perſpiration, by which the *gout* may be either removed or prevented. The patient ought likewiſe to be kept cool and eaſy during the fit, for every thing that affects the mind diſagreeably, and tends to throw the *gout* on the ſtomach, is dangerous. We may obſerve, in general, that the great effort of nature to free herſelf from an enemy is ſudden; it ought to be promoted, and not reſtrained, by cordials or aromatic applications or remedies.

The uſe of ſalivation has been recommended by ſome in theſe cafes; and Dr. James has found, after repeated trials, a common mercurial courſe very effectual in the cure of the *gout*.

A total

A total milk and seed diet will, it is said, cure the *gout*. See Cheyne's Nat. Meth. of Curing, p. 266.

Dr. Dover says, a *gouty* patient will be free in two or three hours at farthest, after taking a dose, from forty to seventy grains, of the following powder: take salt-petre, and tartar vitriolated, each four ounces; put them into a red-hot mortar, stir them with a spoon till they have done flaming, then powder them very fine, and after that sift in an ounce of opium; grind those to powder, then mix it with an ounce of the powder of ipecacuanha, and as much of the powder of liquorice. This is to be taken going to bed, in a glass of white wine posset-drink, covering up warm, and drinking a quart or more of posset drink while sweating.

The doctor is also of opinion, that Mynsicht's elixir of vitriol often taken, though it may cause pain for some time, yet most certainly destroys the *gouty* matter in the end. Med. Ess. Edinb.

The *gout* powder of the duke of Portland, who brought the receipt with him from Switzerland a few years ago, has been much recommended both for this disorder and the rheumatism. The manner of preparing it is as follows: take of the root of aristolochia rotunda, or birthwort, and of gentian, and of the tops and leaves of germander, green pine and centaury, dried, powdered, and sifted, equal weights; mix them well together, and take one dram of this mixed powder every morning fasting in a cup of wine and water, broth, tea, or any other liquid; keep fasting an hour and a half after it; and continue this course for three or four months without interruption; then diminish the dose to three-fourths of a dram for three months longer, then to half a dram for six months more, taking it regularly every morning, if possible. After the first year it will be sufficient to take half a dram every other day. As this medicine operates insensibly, it must be persisted in for two years or more, and in the use of it the patient is not confined to any particular diet, so that he lives soberly, and abstains from those meats and liquors that have always been accounted pernicious to the *gout*, as champagne, drams, high sauces, &c. Dr. Clephane has shewn, that the *diacrocumon* of Celsus Aurelianus, and the *acidulæ ex duobus centaurea generibus* of Actius, were the same medicine, and are the old names for the duke of Portland's powder. This medicine is at present in high esteem with many; but an indiscriminate use of it in all cases may bring it into disrepute. Med. Obs. &c. vol. 1. art. 14. p. 126, &c.

When the fits are thoroughly off, bleeding should never be omitted, spring and autumn; and in people of succulent habits, purging upon the parts is often very useful; with women, the menses are to be considered before all things, and brought to their regular periods before any hope of a cure can be had. In men, the application of leeches to the hæmorrhoidal veins is of service, and four times, at least, in the year purging remedies, such as rhubarb, senna, and the like, are to be taken in decoctions, or infusions, mixing with them such things as are known to sweeten the blood. And in the general regimen, a sufficient quantity of weak liquors is to be always drank, and a moderate exercise of the body is to be kept up. And finally, as the spring and autumn are the times at which the fits of all *arthritic* diseases usually return, it will be proper, by way of prevention, to take at such times decoctions or infusions of sassafras, or the other woods, in the manner of tea, and with them a few moderate doses of some of the nitrous medicines.

Above all things, when a fit is gone off, the occasional causes of its return are to be avoided; these are a too rich diet, the drinking too much wine, an immoderate use of venery, violent emotions of the mind by anger, or other passions, and violent and immoderate exercises; if these are not refrained, the return of ease will probably be of but very short duration.

The patient should also take a gentle dose or two of the bitter tincture of rhubarb, or some other warm stomachic purge. He should likewise drink a weak infusion of stomachic bitters in small wine or ale, as the Peruvian bark, with cinnamon, Virginian snake-root, and orange-peel. His diet should be light and nourishing, and his exercise regular and gentle. In order to prevent the *gout*, universal temperance and sufficient exercise are of principal importance. Going to bed betimes, and rising early, will be of great use. Night studies, and intense application, late and full suppers, and all strong liquors, especially generous wines and sour punch, should be avoided. Beside the course already prescribed, an issue, or perpetual blister, has a great tendency to prevent the *gout*. Bath waters are of great service in promoting digestion, and invigorating the habit. Cheyne observes, that a dram of powdered sulphur, or flour of brimstone, taken regularly in a spoonful of milk, has prevented the fit for many years.

Though there is little room for medicine during a regular fit of the *gout*, yet when it leaves the extremities, and falls on some of the internal parts, proper applications to remove and fix it become absolutely necessary. Mulgrave had a high opinion of the ALCOHOL *mortis* in this views When the *gout* affects the head, the pain of the joints ceases, and the swelling disappears, while either severe head-ach, drowsiness, trembling, giddiness, convulsions, or delirium, come on. When it seizes the lungs, great oppression, with cough and difficulty of breathing ensue. In these cases, the feet must be frequently bathed in warm water, and acrid cataplasms applied to the soles. Bitttering plasters ought likewise to be applied to the ancles or calves of the legs. Bleeding in the feet or ancles is also necessary, and warm stomachic purges. The patient should also be kept warm. When the *gout* attacks the stomach, extreme sickness, vomitings, anxiety, pain in the epigastric region, and total loss of strength succeed. In this case, the most warm cordials are necessary, as Rhenish wine boiled up with cinnamon or other spices, cinnamon-water, peppermint-water, or even rum and brandy. The patient should keep his bed, and promote a sweat by drinking warm liquors; and if he be troubled with a nausea, drink camomile tea, or any thing that will make him vomit freely.

When the *gout* attacks the kidneys, and resembles gravel-pains, the patient should drink freely of the decoction of marshmallows, and have the parts fomented with warm water. An emollient clyster should be administered; and when the pain is violent, twenty or thirty drops of laudanum may be taken in a cup of the decoction.

The approaches of the *gout* should be attentively observed, and this disorder distinguished from all others, left by an improper treatment the patient should fix falling headachs, coughs, and pains of the stomach and intestines, and at last fall a victim to this disease, by its attack on some of the more noble and vital parts. Buchan's Dom. Med. chap. 38.

Monsieur de Sault being of opinion, that the *gout* depends on the want of perspiration, proposes warm baths, exercise, keeping always warm, and defending from cold; clean cloaths, moderate eating, abstaining from supper, tranquillity of mind, friction and milk diet, as preservatives from it. Garlic being observed by Sanctorius to increase perspiration, is recommended; as the cortex Peruvianus and steel, in winter. When the stomach is attacked he lets blood at the ancles, and applies epispastics of different kinds to the feet, and then endeavours to procure a general sweat. When the pain is very violent he blunts it, by applying a cloth dipped in liquid laudanum to the pained part, and exhorts the patient to use exercise after this. Medic. Ess. Edinb.

Cheyne observes, that mercurial vomits are not only proper for the *gout* in the stomach, but that they are absolutely necessary, as well as the mercurial purges, when the *gout* becomes fixed to and permanent in any part, and also when it is dispersed all over the habit like a rheumatism; that these active medicines must first render the humours fluid, which gum guaiacum, with diaphoretic antimony, will afterwards carry off.

GOUT-*wort*, in *Botony*. See ANGELICA.

GOUTY *land*, in *Agriculture*, a term used by the farmers to denote a hollow sozzey black earth with little springs, that have no free outlet, and therefore swell and elevate the surface in many places.

GOWN, *robe*, a long upper garment, worn by lawyers, divines, and other graduates, who are hence called *gentlemen of the gown*, or *gown-men*.

The *gown* is an ample sort of garment, worn over the ordinary cloaths, hanging down to the feet. It is fashioned differently for ecclesiastics, and for laymen.

At Rome, they give the name *virile gown*, *toga virilis*, to a plain kind of *gown*, which their youth assumed when arrived at puberty. This they particularly denominated, *prætexta*.

In some universities, physicians wear the scarlet *gown*. In the Sorbonne the doctors are always in *gowns* and caps. Besides, &c. wear *gowns* of two colours.

Among the French officers, &c. they distinguish those of the *short gown*, or robe; which are such as have not been regularly examined. They have also barbers of the *short gown*, who are such as are obliged to practise in an inferior way to surgeons, or those of the long robe.

GOWN is also taken, in the general, for the civil magistrature, or the profession opposite to that of arms.

In this sense it was that Cicero said, *Cedant arma togæ*.

GRABATARII, GRABBATARII, in *Church Antiquity*, such persons as deferred the receiving of baptism till the hour of death; or who did not receive it till they were dangerously ill, and out of hopes of life: from an opinion, that baptism absolutely washed away all former sins.

The word is formed of *grabatum*, *bed*, and that from

the Greek γραφὶς, a hanging bed, of γράω, *I suspend*: such as was the bed of slaves, poor people, Cynic philosophers, &c. who are enemies of luxury and ease.

GRACCULUS, in *Ornithology*. See JACK-*daw*.

GRACE, GRATIA, in *Theology*, any gift which God confers on men, of his own free liberality, and without their having deserved it at his hands; whether such gift regard the present or future life.

Grace is usually divided into *natural* and *supernatural*.

GRACE, *natural*, includes the gift of being, of life, of such and such faculties, of preservation, &c. St. Jerom, Epist. 150. allows it a *grace* of God, that man was created: *Gratia Dei est, quod homo creatus est.* So also it is by the *grace* of God, that angels and human souls are immortal; that man has free-will, &c.

GRACE, *supernatural*, is a gift from above, conferred on intelligent beings, in order to their salvation.

These only, are called *grace* in the rigour of theology; and it is for the conveyance, improvement, and strengthening of these, that the sacraments are conferred, the ministry of the word instituted, &c.

Divines distinguish supernatural *grace* into *habitual* and *actual*; *justifying* and *sanctifying*.

GRACE, *habitual*, is that which resides statedly in us, is fixed in the soul, and remains till some grievous wilful sin expunge it. This is also called *justifying grace*, as it makes us appear righteous and innocent before God: and *sanctifying grace*, as it makes us holy and devoted to God.

GRACE, *actual*, is that which God gives us for the special performance of some particular good thing; as to convert us, enable us to fulfil a temptation, &c.

This the divines subdivided into divers kinds; *preventing*, *concomitant*, and *subsequent grace*.

It is an article of faith, 1. That actual *grace* is necessary for the beginning, carrying on, and finishing every good work. 2. That the will is able to resist the *grace*, and reject it.

And hence *grace* becomes farther divided into *efficacious* and *sufficient*. It is *efficacious*, or efficient, when it produces the effect; and *sufficient* when it does not, though it might have produced it.

Some of the more rigid Calvinists, &c. admit a necessitating *grace*.

We also say *the law of grace*, *the covenant of grace*, in opposition to the Mosaic LAW, &c. See REVELATION, &c.

GRACE, *act of*, properly denotes an act of amnesty, or oblivion; for the pardon of all offenders who are qualified, or come within the conditions of it.

The term is also sometimes extended to an act made for relief of insolvent debtors in the several prisons; by setting those who are qualified, at liberty from their debts, and confinement.

GRACE, *days of*, or *respite*. See DAYS *of Grace*.

GRACE, in *Law*, is sometimes used for a faculty, licence or dispensation; but this seemeth to be only in a case, where the matter proceedeth, as it were, *ex gratia*, of *grace* and favour; and not where the licence or dispensation is granted of course or of necessity.

GRACE is also a term in the formula of all patents, &c. which begin, George, by the *grace* of God, king of Great Britain, &c. The Romish bishops frequently began their mandates in the like manner: Such-a-one, by the *grace* of God, and the holy see, bishop of, &c.

The English ARCHBISHOPS by, by divine *grace*, or divine providence.

All sovereigns use the plural *grace* of God; as emperors, kings, princes, &c. Anciently dukes, counts, and even lords, used to the same style. In the new collection of Fath. Martene we meet with a mere seigneur, or lord, qualified by the *grace* of God. seigneur de Comborn. Louis XI. forbad the duke of Brittany to style himself by the *grace* of God.

GRACE is also a title of dignity, attributed to princes of inferior rank, and who are not qualified for that of highness.

In former times the kings of England were addressed under the title of *grace*, as they now are under that of majesty. See KING.

Our English dukes and archbishops are still addressed under the title of *grace*. But that title is most frequent in Upper Germany, and particularly Austria where it is borne by the bishops, as being inferior to that of excellence.

GRACE is also applied to persons, and various kinds of performances, to denote a quality, or rather the result of a combination of qualities, which attracts peculiar notice, and affords peculiar pleasure.

GRACE is also used for a short prayer offered before and after meat. This practice is very ancient, and has very generally obtained both in the heathen and Christian world; and hence *grace-cup* is used by some of our poets for the cup or health drank after *grace*.

GRACE, *herb of*, in *Botany*. See RUE.

GRACES, GRATIÆ, in the *Canon law*, are the same with what we otherwise call *provisions*.

GRACES, *expectative*, *gratiæ expectativæ*. See EXPECTATIVE.

GRACES, GRATIÆ, *Charites*, in the *Heathen Theology*, were fabulous deities, three in number, who attended on Venus.

Their names are Aglia, Thalia, and Euphrosyne; shining, flourishing, and gay; and they were supposed by some to be the daughters of Jupiter and Eurynome the daughter of Oceanus; and by others to be the daughters of Bacchus and Venus. Vossius de Idol. lib. 2. cap. 15.

Some will have the *Graces* to have been four, and make them the same with the *Horæ*, HOURS, or rather with the four seasons of the year.

A marble in the King of Prussia's cabinet represents the three *Graces* in the usual manner, with a fourth, seated, and covered with a large veil, with the words underneath, AD SORORES III. Yet Mons. Begar will by no means allow the *Graces* to have been four: the company there present, he understands to be the three *Graces*, and Venus, who was their sister, as being daughter of Jupiter and Dione.

They are always supposed to have hold of each other's hands, and never parted. They were painted naked to shew, that the *Graces* borrow nothing from art, and that they have no other beauties than what are natural.

Yet, in the first ages, they were not represented naked, as appears from Pausanias, lib. vi. and lib. ix. who describes their temple and statues. They were of wood, all but their head, feet, and hands, which were white marble. Their robe, or gown, was gilt; one of them held in her hand a rose, another a dye, and the third a sprig of myrtle.

GRACILIS, in *Anatomy*, a muscle of the leg, thus called from its slender shape. See *Tab. Anat. (Myol.) fig.* 1. *n.* 54. *fig.* 2. *n.* 37. *fig.* 6. *n.* 37.

It arises partly tendinous, and partly fleshy, from the os pubis internally, between the first and second heads of the triceps; and in its descent on the inside of the thigh, grows narrow, and becomes tendinous, a little below the tuberosities, and is thus inserted into the tibia. It assists in bringing the thigh and leg inwards.

GRACILIS *rectus*, in *Anatomy*, a name given by Riolan to one of the muscles of the leg, called by Winslow the *rectus cruris anterior*, and by Cowper the *rectus femoris*. Albinus calls it the *rectus cruris*.

GRACULA, in the Linnæan system of *Ornithology*, a distinct genus of birds, of the order of the *Pinnæ*. The distinguishing character of which is, that the beak is of a convex sharp figure, almost naked at the base; the tongue is entire, a little acute and fleshy; and the feet are ambulatory. Of this genus, Linnæus reckons eight species, none of which are found in Europe.

GRACULUS *palmatus*, in *Ornithology*, a name given by some to a bird, called in England the shagge, and by Mr. Ray the CORVUS *aquaticus minor*, or lesser cormorant, being regularly a species of that bird.

GRADATION, the act of ascending step by step, to any pitch or eminence: from the Latin *gradus*, degree, step.

GRADATION, in *Architecture*, signifies an artful disposition of parts, rising, as it were, by steps or degrees, after the manner of an amphitheatre; so that those placed before do no disservice, but rather service, to those behind.

The painters also use the word *gradation* for an insensible change of colour, by the diminution of the teints and shades.

GRADATION, in *Chymistry*, is a kind of process belonging to metals. It consists in gradually refining, or exalting them to a higher degree of purity and goodness, so as to increase their weight, colour, consistence, &c.

GRADATION, in *Logic*, is an argumentation, consisting of four or more propositions, so disposed as that the attribute of the first is the subject of the second; and the attribute of the second is the subject of the third and so on, till the last attribute come to be predicated of the subject of the first proposition. As in Porphyry, man is an animal; an animal is a living thing; a living thing is a body; a body is a substance: therefore man is a substance.

An argument of this kind is liable to many faults, both from the ambiguity of words and things; e. g. Peter is a man; man is an animal; animal is a genus; genus is an universal: therefore Peter is an universal.

GRADATION, in *Rhetoric*, is when a series of considerations or proofs is brought, rising by degrees, and improving each on the other. See CLIMAX.

Sixth

Such is that in Cicero to Herennius: *Africani industria virtutem, virtus gloriam, gloria amulos comparavit.*

GRADO, in the *Italian Music*, signifies *degree*; thus *di grado* is used to denote *conjoint degrees*, which is when the notes rise or fall from space to line, or from line to space, without making any leap of a third, fourth, or other interval. See SALTO.

Di grado ascendente intimates, that all the notes rise by *conjoint degrees*, as *ut, re, mi, fa*, &c.

Di grado descendente, is when all the notes descend or fall by *conjoint degrees*, as *sol, fa, mi, re*, &c. See DEGREE and CONJOINT.

GRADUAL, GRADUALE, was anciently a church-book, containing divers prayers, rehearsed, or sung, after the epistle.

In some of our ancient writers it is read *gradale, graduale, grale*, &c.

After reading the epistle, the chantor ascended the ambo with his *gradual*, and rehearsed the prayers, &c. therein; being answered by the choir; whence the name *gradual*, on account of the steps or degrees of the AMBO.

The *gradual*, or *grale*, which the provincial constitutions of archbishop Winchelsey, made at Merton, A. D. 1305, required to be in every church, was a book containing all that was to be sung by the choir at high mass; the tracts, sequences, hallelujahs, the creed, offertory, trisagium, and also the office for sprinkling the holy water. Gradale, *seu diurnum, a gradibus in tali libro contentis.*

It is sometimes taken for a mass-book, or part of it, instituted by pope Celestine, anno 430. See stat. 37 Hen. VI. cap. 32.

In the Romish church, *gradual* is an appellation still given to a verse which they sing after the epistle, and which was anciently rehearsed on the steps of the altar: though Ugutio gives us another account, and says it took its denomination *gradatim*, because sung in the *gradual* ascent from note to note. Mabe speaks differently still, and will have it to have taken its name because sung while the deacon went up the stairs to the pulpit, to sing the Gospel.

GRADUAL, GRADUALIS, is also applied to the fifteen Psalms, sung among the Hebrews, on the fifteen steps of the temple. Others are rather of opinion, that they were thus denominated because the singers raised their voice by degrees, from the first to the last.

Cardinal Bona, in his treatise of Divine Psalmody, says, the fifteen *gradual* Psalms are intended to represent to the mind, that we only arrive at the perfection of goodness, or holiness, by degrees. He goes on to lay down the fifteen degrees of virtue, corresponding to the fifteen Psalms; five of them are for beginners; five for proficients; and the rest for the perfect.

GRADUATE, a person who has the degrees of any FACULTY. A *graduate* in physic, in divinity, &c. See DEGREE, DOCTOR, &c.

In France, one-third of the benefices of the kingdom are appropriated to *graduates*; viz. all that become vacant in the months of January, July, April, and October.

This privilege of *graduates* is no older than the fifteenth century: it being observed, that men of learning were much neglected by the collators, and patrons of churches, complaint therefore was made to the council of Basil, where this decree was made; which was afterwards confirmed by the Pragmatic Sanction, and again by the Concordat.

GRADUATION is used, in *Mathematics*, for the act of *graduating*, or dividing any thing into degrees.

For an account of the various methods of *graduating* mathematical and astronomical instruments by strait and circular diagonals, and by concentric arcs, &c. see *Plain* SCALE, NONIUS, and VERNIER.

For an account of Mr. Bird's improved method of dividing astronomical instruments, see MURAL *arch*.

We shall here only observe, that Mr. Ramsden, an ingenious mathematical instrument maker of London, has lately published, by order of the commissioners of longitude, an explanation and description of an engine, contrived by him for dividing mathematical instruments, accompanied by proper drawings, in consideration of which the said commissioners have granted to him the sum of 615*l*. This engine consists of a large wheel of bell-metal, supported on a mahogany stand, with three legs; on each leg of the stand is placed a conical friction pulley, whereon the dividing-wheel rests; and to prevent the wheel from sliding off the friction pullies, the bell-metal centre under it turns in a socket on the top of the stand. The circumference of the wheel is ratched or cut into two thousand one hundred and sixty teeth, in which an endless screw acts; so that six revolutions of the screw will move the wheel through one degree. A circle of brass is fixed on the screw-proof, whose circumference is divided into sixty parts, and, therefore, each division will answer to a motion of the wheel of ten seconds, and six of them will be equal to a minute, &c. Several different arbors of tempered steel are truly ground into the socket in the centre of the wheel. The upper parts of the arbors that stand above the plane are turned of various sizes, to suit the centres of different pieces of work to be divided. When any instrument is to be divided, the centre of it is very exactly fitted on one of these arbors, and the instrument is fixed down to the plane of the dividing-wheel by means of screws, which fit into holes made in the radii of the wheel for that purpose. The instrument being thus fitted on the plane of the wheel, the frame which carries the dividing-point is connected at one end by finger-screws with the frame which carries the endless screw; while the other end embraces that part of the steel arbor, which stands above the instrument to be divided, by an angular notch in a piece of hardened steel. The frame carrying the dividing-point or tracer is made to slide on the frame which carries the endless screw to any distance from the centre of the wheel, as the radius of the instrument to be divided may require, and may be there fastened by tightening two clamps; and the dividing-point being connected with the clamps by the double jointed frame, admits a free and easy motion towards, or from the centre, for cutting the divisions, without any lateral shake. In this way an instrument, fitted on the dividing-wheel, may be moved to any angle by the screw and divided circle on its arbor, and this angle may be marked on the limb of the instrument with the greatest exactness by the dividing-point or tracer, which can only move in a direct line tending to the centre, and is altogether freed from the inconveniencies that attend cutting, by means of a strait edge. This method of drawing lines will also prevent any error that might arise from an expansion or contraction of the metal during the time of dividing.

The screw frame is fixed on the top of a conical pillar, which turns freely round its axis, and also moves freely towards or from the centre of the wheel, so that the screw-frame may be entirely guided by the frame which connects it with the centre. By this means any eccentricity of the wheel and the arbor would not produce any error in dividing; and, by a particular contrivance, the screw when pressed against the teeth of the wheel always moves parallel to itself; so that a line joining the centre of the arbor and the tracer continued, will always make equal angles with the screw. For the further construction and use of this engine, see Description of an Engine for dividing Mathematical Instruments, by Mr. J. Ramsden, 4to. 1777.

GRADUS *genitis*. See GENOMIA.

GRÆA, *Tyros*, a name used by the old Greek writers for the wrinkled pellicle which arises upon milk in the boiling.

It was also used in a figurative sense for the wrinkles in the skin of old people.

GRÆCUM. *Album* GRÆCUM. See ALBUM.

GRAFFER, from the French *greffier*, i. e. *scriba*, a *notary*, or *scrivener*. It is used in the stat. 5 Hen. VIII. cap. 1.

GRAFFIO, or GRAVIO, in our *Old Writers*, denotes a *landgrave* or *earl*. *Nec princeps nec* graffio, *hanc limitatem matare audeat.*

GRAFFIUM, in our *Old Writers*, is used for a writing-book, register, or chartulary of deeds and evidences.

GRAFT, or GRAFF, in *Agriculture* and *Gardening*, a little shoot, eyed, bud, or eye of a tree, inserted into another tree to make it yield fruit of the same nature and kind as those of the tree whence the *graft* is taken.

The word is formed of the French *greffe*, which signifies the same thing; and *greffe*, in this sense, is supposed to have been derived from the resemblance the shoot bears to the point of a penknife, which was anciently called *greffe*, Du Cange goes farther, and derives the ancient *greffe* from *graphium*; Menage, from *graphium*, a Latin word, signifying a little style, or iron bodkin, one end whereof was pointed, and served to write on waxen tablets; and the other flat, serving to efface, or rub out what was written.

A *graft* is a little portion of a tree, inclosed in a cleft or incision made in another, in order to correct, qualify, or improve the taste of its fruit; or even to make it bear a different sort of fruit.

In the choice of *grafts*, the following directions should be observed: that they are shoots of the former year; that they may be taken from healthy fruitful trees, neither sickly, nor young and luxuriant; that they be taken from the lateral or horizontal branches, and cut off from the trees before their buds begin to swell, which is generally three weeks or a month before the season for grafting; and, therefore, they should be laid in the ground with the cut downwards, burying them half their length, and covering

covering their tops with dry litter, to prevent their drying. If a small joint of the former year's wood be cut off with the *graft*, it will help to preserve it, and when they are grafted, this may be cut off. When the *grafts* are carried to a considerable diſtance, their cut ends ſhould be put into a lump of clay, and wrapped up in moſs, and thus they will be preſerved freſh for a month or longer; but theſe ſhould be cut off earlier from the trees than thoſe which are to be grafted near the place where the trees are growing. Miller. See FRUIT-*trees*.

GRAFTING, or GRAFFING, or INGRAFTING, in *Agriculture* and *Gardening*. See GRAFTING.

GRAFTING wax. See WAX, &c.

GRAIN, GRANUM, primarily denotes a fruit, or ſeed, growing in a ſpica, or ear.

In this ſenſe, *grain* comprehends all ſorts of corn; as WHEAT, RYE, BARLEY, OATS, &c.

GRAIN, *ſtructure of*. There are three particulars obſervable in every *grain*, whether it be wheat, barley, oat, or whatever elſe of that kind. Theſe are, 1. The outer coat or peſſicle, which contains all the reſt. This in the ſame ſpecies of *grain* is found to be very different in thickneſs in different ears, and as it has grown in different ſoils. 2. The germ or bud; this is always hid within the ſeed or *grain*, and is the plant in miniature that is to ariſe from it. And, 3. The meal, or that farinaceous matter which is incloſed in the ſkin, and which ſurrounds the germ, and ſerves to give it nouriſhment when firſt put into the earth, before it is capable of drawing it from the earth itſelf. Dr. Grew, in his Anatomy of Plants, has treated of this at large. See VEGETATION, &c.

The whole ſtructure of the plant which produces theſe ſeeds is equally admirable. The chaffy huſk is admirably adapted to thieve and defend the ſeed as long as that is neceſſary, and then to let it fall; and the ſtalk formed hollow and round is neceſſarily at once light and ſtrong, capable of ſuſtaining the ear, without abſorbing too much of the juices deſtined to its nouriſhment; and the beards of many kinds are a defence againſt the birds, that would otherwiſe deſtroy the ſeed before its ripenings. The covering of the ſeed is formed of two membranes, which meeting in a line on one part of the ſeed, form together that furrow we ſee on it. This is the place at which the ſeed is to burſt open on being moiſtened. Had not nature provided this means of the germ's coming out, the toughneſs neceſſary to the coat of the ſeed, as a defence from injuries, would have ſuffered the farinaceous matter and the germ to rot together, within it, before it would have given them way to come out, and for the germ to grow.

Nor is this the only uſe of this place of opening. The great Creator of all things has provided theſe ſeeds, not only for a ſupply of the ſame ſpecies of plant, but for our food, and for that of birds, &c. We have art enough to erect machines for the reducing the farina to powder, and the freeing it from its covering membrane; but the birds eat it as it is, and it would paſs through them whole, and without doing them any good, were it not that the juices of the ſtomach ſwelling it up, it burſts open at this furrow, and all the nutritive matter pours itſelf out. Vaes Landes, Trait. Phyſ. p. 92.

This farinaceous matter is compoſed of an infinite number of white and tranſparent bodies, of a globular figure: theſe every way ſurround and incloſe the young plant, and by their figure being eaſily put in motion, as ſoon as the heat and humidity of the earth act upon them, they, by degrees, force themſelves into the veſſels of the plant, and give it increaſe from time to time till they are received into it; and they then have ſo far given it ſtrength, that it is in a condition to feed on the juices in the earth. The ſame proceſs of nature is obſervable in the caſe when *grains* of corn grow out of time, on being thrown too careleſſly together in a moiſt place.

When the corn is ground into powder, theſe farinaceous globules make what we call the flour. The germs are always leſs white, and leſs tranſparent than they, but they are of great uſe; ſince it is principally to them that we owe the agreeable flavour of bread, and almoſt wholly to them, that the fermentation of dough is owing, their little parts being, of all others of the *grain*, the moſt eaſily put in motion. And it is alſo to theſe, that the rotting of wheat, preſerved in damp granaries, is to be attributed, their natural tendency being to motion and to corruption, if that motion be given without the neceſſary accidents. That the obſervation of the fermentation of dough, and the lightneſs of bread, being owing to theſe germs, may not ſeem advanced at random, it may be proper to confirm it, by the obſervations of the people employed in making bread for the army. Theſe people always find, that fine flour, if well dried, and put up in dry barrels, will keep good a long time; but that after it has been thus kept long, though it will make biſcuit, and ſerve for many other neceſſary uſes, it will never make the fine light bread eaten at table; and this they attribute to the life of the flour being ſpent; that is to theſe germs being deſtroyed, as to their vegetative power, by having been a long time broken to piece. See CORN.

For the laws relating to the importation and exportation of ſeveral ſorts of *grain*, as wheat, barley, oats, &c. See WHEAT, HOUSEHOLD, OATS, &c.

GRAIN is alſo applied to the fruits or ſeeds of divers plants, as a *grain* of millet, of pepper, &c.

GRAIN is alſo extended to a minute body, or parcel of a body pulverized. In which ſenſe we ſay, a *grain* of ſalt, a *grain* of ſand, a *grain* of gunpowder, &c.

GRAIN denotes alſo a ſmall weight, uſed in eſtimating very ſubſtances.

The *grain* is the ſmalleſt of all weights known in England. It is taken from the weight of a *grain* of wheat, gathered out of the middle of the ear, and well dried. By ſtat. 12 Hen. VII. cap. 7. every ſterling or penny-weight was to weigh thirty-two ſuch *grains*; but now twenty-four grains make a penny-weight, and twenty penny-weights an ounce. See PENNY and WEIGHT.

The *grain* is troy-weight, and uſed in the weighing of gold, ſilver, jewels, bread, and liquors.

Among the ancients, the *grain* was the fourth part of the ſiliqua, or twelfth of the obolus, and the twenty-ſecond of the drachma. It coincided with the

Fermelius, lib. iv. cap 6. Method. Medend. affirms it as a thing known and certain, that the *grain* is of the ſame weight every where; but he is miſtaken. Mr. Greaves, in his treatiſe of the Denarius, in his Miſcell. Works, vol. i. p. 276, has ſhewn, that 179 Dutch *grains*, which Snellius had found to be the weight of a Philip of gold, only amount to 134½ Engliſh *grains*. And, that Alomi, Perrault has computed the French *grain* to be leſs than the Engliſh, and yet bigger than the Dutch: to the Engliſh, it is as 158 to 134½; and to that of Holland, as 158 to 179. See WEIGHT.

The *grain* uſed by the apothecaries is the ſame with that of the goldſmiths; though they make a difference in the weights raiſed therefrom. Thus, 20 *grains*, with them, make a ſcruple, 3. 3 ſcruples, a drachm, 3. 8 drachms, an ounce, ℥, &c.

The carat uſed in eſtimating the fineneſs of gold as well as in weighing diamonds and precious ſtones, is alſo divided into four *grains*; and the carat in about the one hundred and fiftieth part of an ounce troy, according to Mr. Jeffreys, in his treatiſe on Diamonds and Pearls.

Hence, the Jewellers *grain* is to the troy *grain*, inverſely, as 600 is to 480, that is directly as 4 to 5.

GRAIN is alſo uſed for the figure or repreſentation of *grains* on ſtones, ſtuffs, leathers, &c. Thus, we ſay, morocco has a bolder and richer, that is, a larger *grain*, than ſhagreen.

In ſome marbles, the *grain* is very fine; in others coarſer. Steel is known by its *grain*, which is much finer than that of iron.

GRAIN *of iron*. Even iron has its *grain* as well as wood, and that not the ſame in all iron, though all iron is very evidently the ſame ſpecies of body. The common call iron has a *grain* very different from that which has been hammered, or wrought, the granules which compoſe the maſs being in this laſt ſtate forced as it were into combinations with one another, by the repeated blows of the hammer: the tempering of iron into ſteel alſo alters its *grain*, partly by means of the ſalts and ſulphurs, which are by that operation introduced into it, and partly by the ſtopping the effect of the fiery particles received into it at a certain time.

But beſide theſe differences, the common wrought iron has in its ſeveral pieces, or ſometimes in the ſeveral parts of the ſame piece, different *grains*. Firſt a laminated one, ſecondly a granulated one, and thirdly a fibroſe or ſtringy one. Theſe, however, are not ſo different, in reality, as they appear to be; for the laminæ, as they become ſmaller, become granules; and arrangements of theſe granules, in long lines, make the fibres of the threaded kind. The artificers, however, know by theſe marks of the *grain* what iron is fitteſt for tempering into ſteel; and they find the laminated pieces to be the worſt of all, and the granulated ones the beſt. Mem. Acad. Sciences Par. 1722. See IRON and STEEL.

Much has been ſaid about the ſeveral ſorts of lead-ores, but theſe are three, juſt as in iron, owing only to the ſize and arrangement of the ſame ſhaped particles as in the iron. The braid grained lead-ore being analogous to the laminated kind of iron, the ſteel grained being equally analogous to the granulated iron, and what is called the antimoniated lead-ore, being in the ſame manner analogous to the fibrous grained

iron, and all in the same manner arising out of one another.

GRAINS, in *Chemistry*, or the seeds of vegetables, are distinguished into emulsive, which yield a considerable quantity of mucilage and oil, which may be separately extracted from them; such are almonds, and the seeds of almost all fruits; and farinaceous, which are entirely composed of a dry substance, easily reducible into a fine powder, called meal. Of this kind are the *grains* of all gramineous and leguminous plants.

GRAIN, *cochineal*. See COCHINEAL.

GRAIN, *scarlet*. See SCARLET.

GRAIN, *oily*, *Anagram*, in *Botany*. See GOLD *of Pleasure*.

GRAIN-*Tin*. See STREAMING.

GRAINS *of Paradise*. See CARDAMOMUM and AMOMUM.

GRAINED *medals*. See MEDAL.

Cross GRAINED *stuff*. See CROSS *grained*.

GRAINING, in *Ichthyology*, the name of a fish found in the Mersey, near Warrington: it resembles the DACE, but is more slender, and has a straiter back.

GRAINING *board* is a board used by the curriers, to give the grain to their leather.

It is made with teeth, or notches, running quite across; into which the soft, moistened, suppled leather being pressed, its surface readily takes the impression. See CURRYING.

GRALLÆ, in *Ornithology*, is an order of birds analogous to the *brutæ* in the class of MAMMALIA, in the Linnæan system; the characters of which are, that the beak is subcylindric and somewhat obtuse; the tongue is entire and fleshy; and the thighs above the knees are bare. This order comprehends eighteen genera, among which are the PHOENICOPTERUS, the ARDEA, SCOLOPAX, TRINGA, &c.

GRAMEN, in *Botany*. See GRASS.

GRAMEN *murorum*, *Musa longissima*. See FESTUCA.

GRAMINEA, in *Antiquity*, is applied to a crown formed of grass, *corona*, bestowed by the Romans on certain of their generals, in consideration of their having saved or rescued an army.

The *grassa corona*, *corona graminea*, was but rarely conferred, and for some signal exploit; when, through the courage or dexterity of a general, an army reduced to the last extremities had been saved, or delivered, and the enemy put to flight.

GRAMINEOUS *herbs*, among *Botanists*, are such as have a long, narrow leaf, with no foot-stalk.

GRAMINIFOLIA, in *Botany*, a name given by Dillenius to a genus of plants, called by Micheli and Linnæus ZANNICHELLIA.

GRAMMAR, the art of speaking properly; that is, of expressing one's thoughts, by signs mutually agreed on for that purpose.

The signs here found most convenient, are articulate sounds; but as these are transient, others have been invented more permanent, viz. *grammata*, γραμματα, letters, whence the name *grammar*.

So that *grammar* is the art of rightly expressing our thoughts by words: and it is either *universal* or *particular*. *Universal grammar* explains the principles, which are common to all languages. See *Philosophical* GRAMMAR. And the *grammar* of any *particular* language, applies those common principles to that particular language, according to the established usage and custom of it.

Grammar is more extensively defined, after Mr. Johnson, the art of expressing the relations of things in construction, with due quantity in speaking, and orthography in writing, according to the custom of those whose LANGUAGE we learn.

Grammar is divided by some authors into four parts, ETYMOLOGY, ORTHOGRAPHY, PROSODY, and SYNTAX.

Others those to divide *grammar* somewhat more obviously into the doctrine of *letters*, or *sounds*, which coincides with orthography and orthoepy; that of *syllables*, their accent, time, &c. which falls in with prosody; that of *words*, their kinds, derivations, changes, analogy, &c. which amounts to etymology; and that of *sentences*, which considers the placing, or joining of words together, called *syntax*.

The chief business of *grammar* is, to decline, conjugate, construe, and spell nouns, verbs, and other parts of speech. It teaches the propriety, and natural force, of each part of discourse; and the reason of all expressions used therein.

So that the *grammar* of any particular language enables us to express ourselves with propriety in that language, and to judge of every phrase and form of construction, whether it be right or not. Besides, there is a secondary use to which it may be applied; viz. the facilitating of the acquisition of other languages, whether ancient or modern.

Some have called *grammar* the *door*, or gate, of the arts and sciences; because none of these are attainable but by means hereof. *Grammar*, according to Quintilian, is that to eloquence, which the foundation is to the building: they who despise it, as only dealing in low, trivial things, are exceedingly mistaken: it had really more solidity than shew.

Diogenes Laertius relates, after one Hermippus, that Epicurus was the first who gave the rules of *grammar* for the Greek tongue; but that Plato was the first who had taken the thing into consideration, and that he had even made some discoveries on that subject.

At Rome, Crates, surnamed Mallotes, contemporary with Aristarchus, gave the first lectures on *grammar* to the Romans, during the time of his being ambassador for king Attalus, to the commonwealth, between the second and third Punic wars, soon after Ennius's death. Before him, it was not known at Rome what *grammar* meant. Polydore Virgil de Invent. Rer. lib. i. cap. 7.

Grammar is the same in all languages, as to its general principles, and notions, which it borrows from philosophy to explain the order and manner wherein we express our ideas by words: but, as each language has its particular turns, its several character, and genius, different from the genius and character of other languages; hence arise as many *grammars* as languages. An example will suffice to shew this: we say in English, *draw a straight line*, not *a line straight*: in French, they say, *tirer ligne droite*, a line straight, not *droite ligne*, a straight line: and in Latin there is a liberty to say it either the one way or the other, *rectam lineam*, or *lineam rectam*, *ducere*. And if there be a language which in the phrase above mentioned follows the same analogy as the English, it differs from it on a hundred other occasions.

Hence Dr. Wallis very justly finds fault with our English grammarians, where he says, that all of them, forcing our English tongue too much to the Latin method, have delivered many useless things concerning cases, genders, and declensions, of nouns; tenses, moods, and conjugations, of verbs: as also the government of nouns and verbs; which our language has nothing to do with.

GRAMMAR is also used for a book containing the rules of *grammar*, which obtain in any language. See LANGUAGE.

The ancient *grammars* are; for the *Hebrew* that of rabbi Juda Chiug, which is commonly held the first Hebrew *grammar* that appeared; though it is certain, rabbi Saadias Haggaon, who lived before rabbi Juda, composed two works in the same kind: one, expressly of *grammar*; and the other of the elegancies of the Hebrew tongue.

For the *Greek*, the oldest *grammar* is that of Gaza: the *Latin* ones are the works of Martinius Capella, Priscian, and Alcuinus Pedianus.

The modern *grammars* are: 1. For the Hebrew, that of Pagninus, the edition of Hen. Stephens; or le Preux: at Geneva, in 1592: that of Petrus Martinius at Rochel 1592, that of Buxtorf: that of Ludovicus Deus, in three languages: that of Statinus Amama, which is a collection from Martinius and Buxtorf; that of Belarmine, with the notes of Muis; those of F. Selanther, of W. Schickard, and of Vich. Bythner, to the latter of which is annexed a brief account of the Chaldee, are useful for beginners. 2. For the *Chaldee*, the best are those of Martinius, Buxtorf, and Lud. Deus, in three languages. 3. For the *Syriac*, those of Amira, Myriæus, Waferus, and Beveridge; with the Chaldee and Syriac ones of Buxtorf, of Lud. Deus in three languages, and that of Lembden. 4. For the *Coptic*, the Prodomus Coptus, and Lingua Ægyptiaca Restituta of Kircher. 5. For the *Arabic*, that of Erpenius, and that of Golius, which is only Erpenius's a little augmented. 6. For the *Ethiopic*, that of J. Ludolphus. 7. For the *Persian*, that of Lud. Deus. 8. For the *Armenian*, those of Schroder, and Galanus. 9. For the *Greek*, those of Mart. Rulandus, Sylburgius, F. Mocquet, Vossius, Busby, and Port Royal. 10. For the *Latin*, those of Despauter, the Minerva of Sanctius, those of Vossius, and Sprat; that of Port Royal, which is only a collection from the rest; and that of Lowe, the most exact of all. 11. For the *Italian*, those of Berger, Lanfredini, Port Royal, and Veneroni. 12. For the *Spanish*, those of Salazar, Port Royal, the abbot de Vairac, &c. 13. For the *Portuguese*, that of Pereira. 14. For the *French*, those of the abbé Regnier, and F. Buffier. 15. For the *High Dutch*, those of Clajus, Hertshurgenius, Schottelius, Bondicher, and Steinbach. 16. For the *English*, those of Wallis, Brightland, Greenwood, Lowth, and Priestley.

GRAMMAR is also used in the same sense with elements; as geographical *grammar*.

Philosophical GRAMMAR, is that which, without regarding the several idioms of particular languages, only respects

those principles that are essential to them all. One of this kind was proposed by lord Bacon; not upon the analogy of words, but such as should diligently examine the analogy or relation between words and things. He disapproves too curious an enquiry about the original imposition and etymology of names. This he thinks an elegant, and as it were, a waxen subject, that may be handsomely wrought and twilled, but is attended with little truth and advantage. But, says he, it would be a noble kind of *grammar*, if any one well versed in languages, both the learned and the vulgar, should treat of their various properties, shewing wherein each of them excel and fall short: for thus languages might be enriched by mutual commerce, and one beautiful image of speech, or one grand mode of language, for justly expressing the sense of mankind, be formed like the Venus of Apelles, from the excellencies of several. And thus at the same time we should have some considerable marks of the genius and manners of people and nations, from their respective languages. See Bacon's Doctrine of Delivery, sect. 7. and De Augm. Scient. vi. 1.

The object of philosophical or universal *grammar* is speech or language, as divided into its constituent parts, as a statue may be divided into its several limbs; or else, as resolved into its matter and form, as the same statue may be resolved into its marble and figure: and thus it is distinguished from the art of LOGIC, which considers speech as combined or compounded; so that, by this synthesis, simple terms are combined to produce a truth, and two truths are combined to produce a third, &c. In this kind of *grammar*, the design is to point out the several powers and modes of expression which sounds are capable of, to trace their connexions with, or relation to the ideas they represent; and to shew the actual variety of the external expressions of the same mental conceptions which different languages exhibit. By this comparison we shall be enabled to judge which is the most adequate and convenient method of expression, what is defective and what is redundant in the structure of any particular language, and direct to the most proper method of supplying the defect, or lessening the inconveniences arising from the superfluity. See LANGUAGE. See an excellent and well known work of this kind by the ingenious and learned Mr. Harris, called the Hermes, or a Philosophical Enquiry concerning Universal Grammar, 2d edit. 1765.

GRAMMAR, *aberrations in*. See CHARACTER.

GRAMMARIAN, GRAMMATICUS, a person well versed in grammar: or who teaches grammar.

The denomination *grammarian* is, like that of critic, now frequently used as a term of reproach; a mere *grammarian*; a dry, plodding *grammarian*, &c. The *grammarian* is conceived as a person wholly attentive to the minutiæ of language; industriously employed about words, and phrases; and incapable of perceiving the beauties, the delicacy, finesse, extent, &c. of a sentiment.

Scaliger, however, considered *grammarians* in another light. *Ultimam illam*, says he, *bonis* grammaticus *suffecisse in ei, qui omnes auctores probe vult intelligere, esse* grammaticum.

The title *grammarian*, it is certain, was anciently a title of honour; being given not only to such as applied themselves to grammar, or excelled in philology; but to all who were reputed learned in any art or faculty whatever, as it shews by Ger. Vossius, in his book of grammars.

The word was properly a title of literature and erudition, and was frequently given to persons who excelled in all, or many arts, called also *polyhistors*.

Thus, Philoponus, a famous philosopher in Justinian's time, remarkable for the extent and variety of his knowledge, was surnamed *Grammaticus*, as appears from Photius's Bibliothec.

So Saxo, the Danish historian, in the thirteenth century, got the appellation *Grammaticus*: and as late as the year 1580, Thomas d'Aversa, a celebrated Neapolitan lawyer, was surnamed the *Grammarian*.

The title *grammarian* was anciently bestowed on those we now call *critics*, men of learning, erudition, letters, &c. and particularly such as wrote well, and politely, in every kind.

It is in this sense that Suetonius intitles his book which he wrote on the best Latin authors, *Of the celebrated Grammarians*; and that Cornelius Nepos calls the commentators on the orators and poets, *grammarians*; and lastly, it is in this sense the appellation is attributed by the ancients to Apion, Philoponus, and Solinus.

The most celebrated *grammarians* of the second century were Ager, Pollio, Eutychius, Proculus, Athenæus, Julius Pollux, Macrobius, and Aulus Gellius; the works of these last authors are an assemblage of abundance of very different things, and subjects, relating to the criticism of the ancient writers, and the polite literature.

If the name have lost its ancient honour, it is through the fault of those who have assumed it; by their treating of *grammar* in a low, pedantic, dogmatic manner; reducing it to words and syllables; and dwelling altogether on trifling puerile remarks, and censures: whereas its ancient office was, to make an accurate and thorough examen of an author; to enter into all his views; to point out the beauties, and the defects thereof; to distinguish the true beauties from the false; and the genuine productions of an author, from the supposititious: that is, a *grammarian* was then, what we call a critic now.

Those who only taught to read, understand, and explain authors, were called *grammatistæ*, *grammatistæ*; in contradistinction from *grammatici*: though, in course of time, the *grammatistæ* have risen in the place of *grammatici*; who are now preferred to that of *critici*.

GRAMMATICAL, something relating to GRAMMAR.

We say, *grammatical* construction; *grammatical* signification, &c. Idioms, as Anglicisms, Latinisms, Græcisms, Gallicisms, &c. deviate from *grammatical* strictness. Such a phrase is not *grammatically* just; it is an idiom.

GRAMMATICAL *criticism*. See CRITICISM.

GRAMMELOUC, in *Natural History*, the name of an East Indian shrub, very common in the woods and forests. It grows to five or six feet high: its leaves are very long and narrow, and terminate in a point: they are of a lively green: the fruit is carried in a bag of a triangular shape, of the size of a hazel-nut. but somethings longer; on opening this there appear three cells, in each of which is contained one fruit, resembling the seed of the palma Christi, but covered with a transparent pellicle, and a black one under that: the inside of the fruit is white, and is of a sharp and pungent taste. It is a very violent medicine, operating both by stool and vomit, and that often so as to endanger the life of the person who has taken it. They allay its operation by eating BETEL. Mem. Acad. Par. 1699.

GRAMPUS, in *Ichthyology*, the *delphinus orca* of Linnæus, an English name given to one of the cetaceous fishes, properly of the genus of the DELPHINUS, or dolphin, according to the new Artedian system, and distinguished from the others of that genus by the name of the *dolphin* with the snout bending upwards, and with broad serrated teeth. This is the orca of almost all the ancient as well as modern writers, and it called the *leper* and *north-esper* by the people of Scotland. Sir Robert Sibbald gives it the name of the *balæna*; but he distinguishes it from the common whale by its smaller size, and having teeth in both the jaws; and his account of the teeth of this fish differs from that of Linnæus and Artedi. According to him there are thirty in each jaw; those before are blunt, round, and slender; the farthest sharp and thick; between each is a space adapted to receive the teeth of the opposite jaw, when the mouth is closed. Paulus Jovius calls it also *capidolium*. These are all the names it is known by; and that of PORPESSE is sometimes ignorantly given to it, but properly belongs to another species of the same genus, the PHOCÆNA.

The spout-hole of this fish is in the neck; the situation and number of the fins agree with the dolphin; the colour of the back is black, but on each shoulder is a large white spot, the sides marbled with black and white, and the belly of a snowy whiteness; its length is from fifteen to twenty-five feet, and it is remarkably thick in proportion to its length. This fish is extremely voracious; destroys the porpesse, and is said to be a great enemy to the whale, fastening on it like a dog on a bull, till it roars with pain. The *grampus* is sometimes found on our coasts, but most abounds off the North Cape in Norway. Pennant.

GRANA *tiglia*, in the *Materia Medica*, the fruit of a species of RICINUS.

GRANA *paradisi*, or greater CARDAMOMS, are the seeds of the AMOMUM of Linnæus.

GRANA *regia*, in the *Materia Medica*, the seeds of the common RICINUS, called by some PALMA *Christi*.

GRANADIER, GRENADIER, or GRANADIER, a soldier who is armed with a firelock, bayonet, and hanger, a pouch full of hand-grenades to be thrown among the enemy, and a cartridge-box that will hold ten or twelve rounds. They wear a high cap, usually adorned with a piece of brass, but now with fur, and a piece of cloth upon their shoulders, called a *wing*. They were first established in France in 1667, and soon after formed into companies: they were first known in England in 1685. There are companies of *foot granadiers*, and *horse granadiers*, or *granadiers* of horse, by the French called *granadiers*

hadiers volant, or *flying grenadiers*, who are mounted on horſeback, but fight on foot and on horſeback. Theſe were firſt eſtabliſhed in France by Lewis XIV. in 1676, and formed into ſquadrons.

Every battalion of foot, of late years, has generally a company of *grenadiers* belonging to it; or elſe four or five *grenadiers* belonging to each company of the battalion; which, on occaſion, are drawn out, and form a company of themſelves. Theſe generally take the right of the battalion; and are the firſt in attacks.

We have in England two troops of *horſe-grenadier* guards; the firſt raiſed in the year 1693, and the ſecond in 1702.

GRANADILLA. *See* PASSION *flower*.

GRANADO, GRANADA, or GRENADE, in the *Military Art*, a hollow ball or ſhell, of iron, braſs, or even glaſs, or potters earth, filled with gunpowder, and fitted with a fuzee to give it fire.

The name *granado* takes its riſe hence, that it is filled with grains of powder, as a pomegranate is with kernels.

Of theſe there are two kinds; the one large, the other ſmall: the firſt are to be thrown at the enemy by a mortar, properly called BOMBS, or SHELLS. The latter to be caſt with the hand, and thence denominated *hand-granados*.

The beſt way, Caſimir obſerves, to ſecure a man's ſelf from the effect of a *granado*, is, to lie flat down on the ground, before it burſt.

The common, or hand *granado*, is a little, hollow ball of iron, tin, wood, paſteboard, or other matter, filled with ſtrong powder, lighted with a fuzee, and thus thrown by hand into places where men ſtand thick; and particularly into trenches and lodgments.

Their compoſition is the ſame with that of BOMBS; which ſee. For ſize, they are uſually between two and three inches in diameter, about the bigneſs of a common iron bullet, and weigh about three pounds: as to dimenſions, they are commonly in thickneſs one eighth, one ninth, or one tenth of their diameter; their aperture, or orifice about $\frac{1}{4}$ wide, as preſcribed by Caſimir.

Thuanus obſerves, that the firſt time *granados* were uſed, was at the ſiege of Wachtendonck, a town near Gueldres; and that the inventor was an inhabitant of Venice, who, in making an experiment of the effect thereof, occaſioned two-thirds of that city to be burnt; the fire being kindled by the fall of a *granado*.

Bombs were known long before the invention of *granades*. The ancients had a ſort of olliæ, or firepots, ſomewhat of the ſame nature with our *granados*, but they were much leſs perfect.

Caſimir mentions a ſort of *blind granado*, without any aperture, or fuzee, as not needing to be lighted; but being thrown with a mortar, take fire of themſelves whenever they fall on any hard ſolid object.

GRANARY, a building to lay or ſtore corn in, particularly for keeping.

Sir Henry Wotton adviſes, to make it look towards the north, as much as may be; becauſe that quarter is moſt cool and temperate.

Mr. Worlidge obſerves, that the beſt *granaries* are built of brick, with quarters of timber wrought in the inſide, whereto to nail the boards, with which the inſide of the *granary* muſt be lined ſo cloſe to the bricks, that there be no room for vermin to ſhelter themſelves. There may be many ſtories one above another, which ſhould be near to one another; for the ſhallower corn lieth, the better, and it is the eaſier turned.

Some have had two *granaries*, the one above the other, and filled the upper with wheat, or other corn: this upper one had a ſmall hole in the floor, by which the corn deſcended into the lower one, like the ſand in an hour-glaſs; and when it was all come down into the lower *granary*, it was then carried up again into the upper one; and ſo it was kept continually in motion: which is a great preſervation to the corn. A large *granary*, full of ſquare wooden pipes, may alſo keep corn from heating.

In the care of public *granaries*, or magazines of corn, one great caution neceſſary, is, the laying up in them ſuch corn as will be leaſt ſubject to decay; and the ſingle thing to be conſidered in this, is the laying up only ſuch as is the product of hot and dry countries. In France the corn of the ſouthern provinces keeps many years longer than that of the other parts of the kingdom; and ancient and modern hiſtory both inform us, that the corn which is the produce of Africa, particularly of the country about Algiers and Tunis, will keep much longer than that of any other country. The Romans, in old time, annually imported vaſt quantities of corn from Egypt; this they found not only to produce much larger crops than ſuch as was the produce of their own country, but to keep many years in their public *granaries* without injury. The Marquis of Santa Cruz, this author of many excellent obſervations on the politic and military ſtate of different nations, obſerves, that in Galicia and the Aſturias the corn will hardly keep in the *granaries* from one year to another, and that it is the humidity it contains that rots and decays it; and that the corn brought from Caſtile will keep good many years. This corn, he tells, is the only kind they ever venture to lay up in the public *granaries* of Spain; and that the whole difference between this and the other, is, that it grows in a country where there is leſs rain in ſummer. Des Landes Trait. Phyſ.

It would be eaſy to import corn from Barbary in ſufficient quantity for all the ſeed-corn of the kingdom; and in countries where the people are ſubject to famine, even for the ſupport of the nation; and the advantage this African corn would have over the European, would be much greater than that of Caſtile is obſerved to have over the produce of the other parts of Spain. Flat bottomed veſſels, of conſiderable burthen, yet not made to draw much water, would be very proper for this ſort of ſervice; and the voyage through the Streights of Gibraltar would, at a proper ſeaſon of the year, be ſhort, and performed at a ſmall expence. We might thus be furniſhed with ſeed-corn, eaſily better than any we can purchaſe at preſent; and France with corn that would guard ſufficiently againſt the miſeries of a famine, which a long war generally brings upon that nation; and if the public magazines for receiving and laying up this corn, were erected near the mouths of the ſeveral larger rivers, the water-carriage would eaſily diſperſe it in time of want to all parts of the kingdom.

The kingdoms of Fez and Morocco might be alſo as good marts for us, though the French are forbid trading for corn in them, on any other condition than that of exchanging military ſtores for them, which they make a point of it not to do. The keeping up a good underſtanding with Algiers and Tunis, is however of ſo much conſequence to us, that we do not ſcruple purchaſing their friendſhip at this price; and we therefore might, if we pleaſed, as well traffic for corn with Fez and Morocco, as with any other the commodities of our country.

The choice of the *grain* being made, and the manner of procuring it regulated, the next conſideration is how to preſerve it; for this purpoſe, we have the concurrent teſtimony both of the ancients and moderns, that ſubterranean caverns, made in a dry ſoil, and preſerved from the ingreſs of the damp air, are the propereſt places. Pliny tells us, that in his time they kept corn a long time in this ſort of ſtore-rooms, covering the bottom with ſtraw, and laying upon that the corn in the ear. We find that corn will be preſerved thus very well, for five, ſix, or ſeven years. And an accident, ſome years ago, diſcovered a parcel of corn thus preſerved at Amiens, which, though it had been laid up a great number of years, was found to be freſh and good, not worm eaten, not rotten, nor even mouldy. This is certainly owing to the moiſt air having been kept out, and with it the eggs of animals, and ſeeds of thoſe minute vegetables, which we ſee in form of mouldineſs on ſuch corn, as has been leſs carefully defended from the acceſs of them. Experimental philoſophy has proved, that the air is the great ſource of corruption; keep out that, and all is kept out; and the moſt corruptible ſubſtances, ſuch as meat, butter, milk, and the like, have been preſerved freſh four months in the exhauſted receiver of an air-pump.

The only objection to this ſcheme for public *granaries* is the expence, but it is not proper that any but a monarch ſhould undertake them; and there does not appear any way in which the public money could be better employed, than in ſo general a good. They have near Grand Cairo a magazine of this kind, defended with good walls, and called Joſeph's *granaries*. It is not probable, that they are quite ſo old as the days of that patriarch, but they abundantly prove the utility of ſuch ſtorehouſes, by the vaſt quantities of *grain* annually preſerved in them.

Many parts of Africa abound with *granaries* of this kind. There are ſo many deep pits made in the ſolid rock, the deſcent into them is but juſt large enough for a man to go down into them by, but they grow larger as ſoon as the perſon is in, and are uſually ſquare, and from thirty to forty feet in diameter. In theſe the great men of the country preſerve their corn; they firſt ſtrew over the floor with ſtraw, then they lay the corn on; ſtill as the heap riſes, placing a thin bed of ſtraw between the corn and the ſides, as they did at the bottom. In this manner they proceed till the whole cavity is filled: when this is done, they cover the mouth of the entrance with a ſort of hurdle of green boughs of trees, interwoven

latterwoven one with another. This they cover with about two feet thickneſs of ſand, and over this they raiſe a ridge of earth, well beat together, in order to throw off the rain both ways, that none may ſettle on the place and ſoak into the magazine.

The corn thus ſtored up always keeps three, four, or more years very good; and not unfrequently, the proprietor being taken off by the ſeverity of the eaſtern governments, under which they live, the magazine is forgotten, and ſome accident diſcovering it many years afterwards, the corn is almoſt always found perfectly good in it. All the care they take, in regard to the corn, is to expoſe it two or three days to the ſun's heat, to dry it thoroughly before they carry it into the magazine.

In the duchy of Lithuania, and in the Ukraine, the people always preſerve their corn in the ſame manner in wells or pits made in dry places; but in theſe countries great care is to be taken in the opening theſe ſtore-rooms; for if people deſcend into them, before they have had ſufficient communication with the freſh air, they are often killed by the damps; this, however, is eaſily guarded againſt; and by theſe and numerous other inſtances of the practice of other countries, it appears evident, that the advantage of thoſe ſubterranean *granaries* over all others is very great.

Though theſe are to be recommended before all others, yet the common *granaries* may, with proper care, be rendered much more uſeful than they are at preſent. The great caution neceſſary to this purpoſe is to guard againſt the too great humidity, which there always is in places, where there is a great number of doors and windows. A too free acceſs of the external air is alſo to be carefully guarded againſt; for this brings in with it the eggs of a vaſt number of different inſects, which prey upon and deſtroy the corn. A third caution is, when the corn is the produce of the country, where it is preſerved, not to fill the place with the crop of one place only, but to mix the harveſts of two as different provinces as may be, the one dry, the other moiſt, or otherwiſe differing as much as may be; thus the contrary qualities of the one will prevent the deſtruction of the other. Theſe are the three great rules to prevent the corruption of corn; but when the miſchief is once begun, it will prove very difficult to ſtop it: all the care that can be employed ſhould therefore be taken in regard to theſe.

The two great cautions to be obſerved in the erecting of *granaries* are to make them ſufficiently ſtrong, and to expoſe them to the moſt drying winds. The ordering of the corn in many parts of England, particularly in Kent, is thus: to ſeparate it from duſt and other impurities after it is threſhed, they toſs it with ſhovels from one end to the other of a long and large room; the lighter ſubſtances fall down in the middle of the room, and the corn only is carried from ſide to ſide, or end to end of it. After this they ſcreen the corn, and then bringing it into the *granaries*, it is ſpread about half a foot thick, and turned from time to time about twice in a week; once a week they alſo repeat the ſcreening it. This ſort of management they continue about two months, and after that they lay it a foot thick for two months more, and in this time they turn it once a week, or twice, if the ſeaſon be damp, and now and then ſcreen it again. After about five or ſix months they raiſe it to two feet thickneſs in the heaps, and then they turn it once or twice in a month, and ſcreen it now and then. After a year, they lay it two and a half, or three feet deep, and turn it once in three weeks or a month, and ſcreen it proportionably. When it has lain two years, or more, they turn it once in two months, and ſcreen it once a quarter, and how long ſoever it is kept, the oftener the turning and ſcreening is repeated, the better the *grain* will be found to keep.

It is proper to leave an area of a yard wide on every ſide of the heap of corn, and other empty ſpaces, into which they turn and toſs the corn as often as they find occaſion. In Kent they make two ſquare holes at each end of the floor, and one round in the middle, by means of which they throw the corn out of the upper into the lower rooms, and ſo up again, to turn and air it the better. Their ſcreens are made with two partitions, to ſeparate the duſt from the corn, which falls into a bag, and when ſufficiently full this is thrown away, the pure and good corn remaining behind.

Corn has by theſe means been kept in our *granaries* thirty years; and it is obſerved, that the longer it is kept the more flour it yields in proportion to the corn, and the purer and whiter the bread is, the ſuperfluous humidity only evaporating in the keeping. At Zurich, in Switzerland, they keep corn eighty years, or longer, by the ſame ſort of methods.

The public *granaries* at Dantzick are ſeven, eight, or nine ſtories high, having a funnel in the midſt of every floor to let down the corn from one to another. They are built ſo ſecurely, that though every way ſurrounded with water the corn contracts no damp, and the veſſels have the convenience of coming up to the walls for the lading. The Ruſſians preſerve their corn in ſubterranean *granaries* of the figure of a ſugar-loaf, wide below and narrow at top: the ſides are well plaiſtered, and the top covered with ſtones. They are very careful to have the corn well dried before it is laid into theſe ſtore-houſes, and often dry it by means of ovens; the ſummer dry weather being too ſhort to effect it ſufficiently. Dantzick is the grand ſtore-houſe, or repoſitory of all the fruitful kingdom of Poland. The wheat, barley, and rye, of a great part of the country, are there laid up in parcels of twenty, thirty, or forty laſts in a chamber, according to the ſize of the room; and this they keep turning every day or two, to keep it ſweet and fit for ſhipping. A thunder ſtorm has ſometimes been of very terrible conſequences to theſe ſtores. All the corn of the growth of former years having been found ſo much altered by one night's thunder, that though over-night it was dry, fit for ſhipping or keeping, and proper for uſe of any ſort, yet in the morning it was found clammy and ſticking. In this caſe there is no remedy, but the turning all ſuch corn three or four times a day for two months or longer; in which time it will ſometimes come to itſelf, though ſometimes not.

This effect of thunder and lightning is only obſerved to take place in ſuch corn as is not a year old, or laſt not ſweated thoroughly in the ſtraw before it was threſhed out. The latter inconvenience is eaſily prevented by a timely care; but as to the former, all that can be done is carefully to examine all ſtores of the laſt year's corn after every thunder ſtorm, that if any of this have been ſo affected, it may be cured in time; for a neglect of turning will certainly utterly deſtroy it. Phil. Tranſ. N° 25, or Abr. vol. ii. p. 629, &c.

According to Vitruvius's rules, a *granary* ſhould always be at the top of a houſe, and have its openings only to the north or eaſt, that the corn may not be expoſed to the damp winds from the ſouth and weſt, which are very deſtructive to it; whereas the contrary ones are very neceſſary and wholeſome to it, ſerving to cool and dry it from all external humidity, from whatever cauſe. There muſt alſo be openings in the roof to be ſet open in dry weather, partly to let in freſh air, and partly to let out the warm effluvia which are often emitted by the corn. The covering of the roofs ſhould always be of tiles, becauſe in the worſt ſeaſons, when the other openings cannot be ſafe, there will always be a conſiderable inlet for freſh air, and a way out for the vapours by their joinings, which are never cloſe. If there happen to be any windows to the ſouth, great care muſt be taken to ſhut them up in moiſt weather, and in the time of the hot ſouthern winds.

There muſt never be a cellar, or any other damp place, under a *granary*, nor ſhould it ever be built over ſtables; for in either of theſe caſes the corn will certainly ſuffer by the vapours, and be made damp in one, and ill-taſted in the other. Mem. Acad. Par. 1708.

Monſ. Du Hamel and Dr. Hales recommend various contrivances for ventilating or blowing freſh air through corn, laid up in *granaries*, or ſhips, in order to preſerve it ſweet and dry, and to prevent its being devoured by weevils or other inſects. This may be done by nailing wooden bars or laths on the floors of the *granary*, about an inch diſtant from each other, when they are covered with hair-cloth only; or at the diſtance of two or three inches, when coarſe wire-work, or baſket-work of other is laid under the hair-cloth, or when an iron-plate full of holes is laid upon them. Theſe laths may be laid acroſs other laths, nailed at the diſtance of fifteen inches, and two or more deep, that there may be a free paſſage for the air under them. The under laths muſt come about ſix inches ſhort of the wall of the *granary* at one end of them; on which end a board is to be ſet edgeways, and ſloping againſt the wall; by this diſpoſition a large air-pipe is formed, which having an open communication with all the interſtices between and under the bars, will admit the paſſage of air below forcibly through a hole at the extremity of it, into all the corn in the *granary*, that will conſequently carry off the noiſome exhalations of the corn. The ventilators for ſupplying freſh air may be fixed againſt the wall, on the inſide or outſide of the *granary*; or under the floor, or in the ceiling; but wherever they are fixed, the handle of the lever that works them muſt be out of the *granary*, otherwiſe the perſon who works them would be in danger of ſuffocation, when the corn is fumed with burning brimſtone, as is ſometimes done for deſtroying weevels.

Small

Small moveable ventilators will anſwer the purpoſe for ventilating corn in large bins in *granaries*, and may be eaſily moved from one bin to another. If the *granary* or corn-ſhip be very long, the main air-pipe may paſs lengthwiſe along the middle of it, and convey air, on both ſides, under the corn. In large *granaries*, large double ventilators, laid on each other, may be fixed at the middle and near the top of the *granary*, that they may be worked by a wind-mill fixed on the roof of the building, or by a water-mill. The air is to be conveyed from the ventilators through a large trunk or trunks, reaching down through the ſeveral floors to the bottom of the *granary*, with branching trunks to each floor, by means of which the air may be made to paſs into a large trunk along the adjoining croſs-walls: from theſe trunks ſeveral ſmaller trunks, about four inches wide, are to branch off, at the diſtance of three or four feet from each other, which are to reach through the whole length of the *granary*, and their farther ends are to be cloſed: ſeams of one-tenth or one twelfth of an inch are to be left open at the four joinings of the boards, where they are nailed together, that the air may paſs through them into the corn. In ſome of theſe leſſer trunks there may be ſliding ſhutters, in order to ſtop the paſſage of the air through thoſe trunks which are not covered with corn; or to ventilate one part of the *granary* more briſkly than others, as there may be occaſion. There muſt alſo be wooden ſhutters, hung on hinges at their upper part, ſo as to ſhut cloſe of themſelves: theſe muſt be fixed to the openings of the walls of the *granary* on their outſide: by theſe means they will readily open to give a free paſſage for the ventilating air, which aſcends through the corn, to paſs off, but will inſtantly ſhut when the ventilation ceaſes, and thereby prevent any dampneſs of the external air from entering; to prevent this, the ventilators ſhould be made only in the middle of dry days, unleſs the corn, when firſt put in, is cold and damp.

In leſſer *granaries*, where the ventilators muſt be worked by hand, if theſe *granaries* ſtand on ſtaddles, ſo as to have their lower floors at ſome diſtance from the ground, the ventilators may be fixed under the loweſt floor, between the ſtaddles, ſo as to be worked by men ſtanding on the ground, without or within the *granary*. A very commodious and cheap ventilator may be made for ſmall *granaries*, by making a ventilator of the door of the *granary*; which may be eaſily done by making a circular ſcreen, of the ſize of a quarter of a circle, behind the door: but in order to this, the door muſt be open, not inwards but outwards of the *granary*, ſo that as it falls back, it may be worked to and fro in the ſcreen: which muſt be exactly adapted to it in all parts of the circular ſide of the ſcreen, as well as at the top and bottom. But there muſt be a ſtop at about eight or ten inches diſtance from the wall, to prevent the door's falling back farther; that there may be room for a valve in the ſcreen to ſupply it with air; which air will be driven in by the door, through a hole made in the wall near the floor, into the main air-trunk, in which there muſt be another valve over the hole in the wall, to prevent the return of the air. See on this ſubject, and the advantages of ventilating different ſorts of grain, Hales's *Uſes of* Ventilators, *part i. p. 81, &c. part ii. p. 220, &c.* See VENTILATOR.

GRANATARIUS, in *Middle Age Writers*, an officer in monaſteries who took care of the proviſions.

GRANATE, popularly called GARNET, in *Natural Hiſtory*, a gem, or precious ſtone, of a high red colour: thus called from the reſemblance it bears to that of the kernel of a pomgranate.

Granates are either *oriental*, or *occidental*: the firſt are brought from divers parts of the Eaſt Indies; the ſecond from Spain, Bohemia, and Sileſia.

Theſe from the Eaſt, are diſtinguiſhed by their colour into three kinds: the firſt, of a deep browniſh red, like black clotted blood; of which kind there are ſome as big as an hen's egg: the ſecond are nearly of the colour of a hyacinth, with which it were eaſy to confound them, but for their ſuperior redneſs. The laſt having a mixture of violet with their red, are called by the Italians, *rubini della rocha*.

The *occidental granates* are of divers reds, according to the places they are found in. Thoſe of Spain imitate the colour of the kernel of a pomegranate: thoſe of Bohemia have a golden caſt with their red, glittering like a live coal: thoſe of Sileſia are the darkeſt of all, and ſeldom thoroughly tranſparent.

Of the occidental *granates*, thoſe of Bohemia are the moſt valued: ſome even give them the preference to the oriental kind. They are found near Prague; not in any particular mines, but picked up by peaſants in the fields, from among the ſands and pebbles.

This is a gem very ſubject to faults and blemiſhes, and is of different degrees of colour in its different ſpecimens, and when perfectly pure and well coloured, it is little inferior to the ruby in beauty.

This gem is the eighth ſtone in hardneſs from diamonds, and fuſible by fire. It is found of various ſizes, from that of a large pin's head, to an inch in diameter; but ſuch large ones are very rare, the largeſt of theſe uſually found not exceeding a fifth of that ſize. It is almoſt always found oblong, or of an irregularly rounded and pebble-like figure and never in angular columns. Its ſurfaces, which are ſometimes ſix, and ſometimes more, are never ſo naturally ſmooth and poliſhed as thoſe of the ruby are, and its colour is a ſtrong red, which taken in different lights, never fails to ſhew the bluiſh caſt. Its degree of colour is very different in the different ſpecimens, and it wants much of the brightneſs of the ruby, as well in its poliſhed as in its native or rough ſtate. Theſe are the determinate characters by which the *garnet* is to be known from all the other red gems. Among our lapidaries and jewellers, genuine *garnets*, according to their different degrees of colour, are known by three different names. 1. The *garnet*, ſimply ſo called; this is the fineſt and moſt valuable kind. It is of a very deep blood-red, with a faint admixture of blue. 2. The *rock-ruby*. This is the name they very improperly give to the *garnet*, when it is of a very ſtrong but not deep red, and has a fainter caſt of the blue. This, when pure and perfect, is an extremely elegant gem. 3. The *ſyrian*, or as they ſpeak it, the *ſerain-garnet*. This is the name by which they call thoſe *garnets*, which are of a yet brighter red, approaching to the colour of native cinnabar, with a faint tinge of blue. 4. The *almandine*. This is the name given to the *garnet* when of the ſame admixture of tinge with what they call the rock ruby, but only a little paler. Hill's Hiſt. of Foſſ. p. 591.

Theſe are the names by which the more expert among our jewellers diſtinguiſh the various appearances of the *garnet*; and which, though to the naturaliſt they are but varieties of the ſame ſtone, yet are to them diſtinct ſpecies of gems, ſince they are of ſeveral different values. But among the leſs judicious of theſe artificers, the names are ſtrangely confounded with one another, and even with different ſtones of other kinds; the blues ometyhſts being by ſome of them called rock-rubies, and the deeper hyacinths ſoriane-*garnets*.

The ancients, though they have not diſtinguiſhed this gem by any peculiar name, yet ſeem to have been very well acquainted with it, and mention its ſeveral appearances, as to its different degrees of colour, as ſo many ſpecies of the carbuncle, the common name by which they called all the red gems: and their anthracites, lapidaſter, and ſandarcius, ſeem to have been only varieties of it.

Some authors, of very diſtinguiſhing judgment, have taken the deeper *garnet* to be the very ſpecies of gem known by the name carbuncle by Theophraſtus; but on comparing the two ſtones together, it appears plainly, that the *garnet*, whoſe colour goes off into a blue, could never give them the idea of a lighted charcoal, or make ſo true a fire-colour in the ſun as the carbuncle, whoſe deep red goes off into a ſcarlet.

Cronſtedt forms a diſtinct order of the *garnets* and the BASALTES, which he calls *terræ granatæ*. The diſtinguiſhing property of theſe *garnet* earths is, that they are more fuſible in proportion as they contain leſs metallic matter, and are more tranſparent and glaſſy in their texture. In other reſpects they reſemble the ſiliceous order of earths. All *garnets* contain iron; moſt of them contain tin alſo, and ſome are ſaid to contain iron and lead. The *granate* is of ſome uſe in medicine: its powder is ſometimes an ingredient in the cordial electuries. The ancients held it excellent againſt heavineſs and melancholy.

GRANATE *paſte*. The counterfeit *garnet* in paſte, is formed with three different proportions of the ingredients, which are theſe:

Take prepared cryſtal two ounces, common red-lead ſix ounces, manganeſe ſixteen grains, zaffer three grains; mix all well together, and put them into a crucible; cover it with a lute, and ſet it in a potter's kiln for twenty-four hours.

Or, take cryſtal two ounces, minium five ounces and a half, manganeſe fifteen grains, *zaffer* four grains; mix them well together, and leave room for their ſwelling in the pot; bake them twenty four hours in a potter's kiln.

The laſt method is this: take cryſtal prepared two ounces, minium five ounces; mix them, and add manganeſe fifty-two grains, zaffer ſix grains; mix them well together, and let all be baked, in a pot well luted, in a potter's kiln for twenty-four hours.

The firſt of theſe makes a very handſome *garnet* of the common tinge; the ſecond, a deep one, with ſomething

of a violet tinge, as many of the natural *gemats* have; but the third makes much the finest and brightest. Neri's Art of Glass, p. 134. See GLASS and PASTE.

GRAND, a term rather French than English, though used on many occasions in our language. It has the same import with *great*, being formed of the Latin *grandis*.

In this sense we say, the *grand* master of an order, the *grand* master of Malta, of the free-masons, &c.

So also, the *grand signor*, the *grand visier*, &c. *grand-father*, *grand-mother*, &c.

In the French polity and customs there are divers officers thus denominated, which we frequently retain in English; as *grand almoner*, *grand ecuyer*, *grand* chamberlain, *grand voyer*, &c.

GRAND *assise*. See ASSISE.

GRAND *cape*. See CAPE and ATTACHMENT.

GRAND *dey*. See DAY, in Law.

GRAND *distresse*, *distressio magna*, a writ of distress, so called on account of its extent, which reaches to all the goods and chattels of the party within the county.

This writ lies in two cases: either when the tenant or defendant is attached and appears not, but makes default; or where the tenant or defendant hath once appeared, and after makes default. On such occasions, this writ lies by common law, in lieu of a peril cape.

GRAND *hercul. in Anatomy*, the name given by Winslow, and the other French anatomists, to the muscle generally called *latissimus dorsi*: by some the *anticeptor* and *anterior*, and by Fallopius *quartus humeri*.

GRAND *gusto* is a term used by painters, to express that there is something in the picture very great and extraordinary, calculated to surprise, please, and instruct.

Where this is found, they say, the painter was a man of *grand gusto*; and they use the words sublime and marvellous, when they speak of a picture, in much the same sense.

GRAND *elisir*, *guard*, *jury*, *lattery*, *prier*, *prevost of France*, *serjeanty*. See ELIXIR, GUARD, &c.

GRANDEE is understood of a lord of the first rank or prime quality.

In Spain, the term *grandees* is used absolutely to denote the prime lords of the court, to whom the king has once given leave to be covered in his presence: there are some *grandees* for life only; made by the king's saying simply, be covered. Others are *grandees* by descent; made by the king's saying, Be covered for thyself and heirs. These last are reputed far above the former.

There are some who have three or four *grandeeships* in their family.

GRANDGOR is used in Scotland for the pox. In the Philosophical Transactions, N° 469. sect. 5. we have a proclamation of king James the IVth of Scotland, ordering all who had this disease, or who had attended others under it, forthwith to repair to an island in the Frith of Forth. If the *grandgor* was the pox, and this distemper came into Europe at the siege of Naples in 1494, it must have made a very quick progress to cause such an alarm at Edinburgh in 1497.

GRANDO, in *Natural History*, a stone more usually called CHALAZIAS.

GRANGE, an ancient term for a barn, or place wherein to lay up and thresh corn.

The word is formed of the Latin *granea*; or of *granum*, *grain*, *corn*, &c. Hence also *granger* or *grangier*, *a grange-keeper* or *farmer*.

GRANGE is also used, in a more extensive sense, for a whole farm, with all the appendages of stables for horses, stalls for cattle, &c. and for an inn.

GRANI, in *our Ancient Writers*, mustachios or whiskers of a beard.

The word seems formed from the ancient British or Irish, *greanr*, *a beard*.

It is given for a reason why the cup is refused to the laity, *Quia barbati*, *& gratiosi habent granos*, *dum poculum inter epulas sumunt*, *prius liquore quàm inficiunt*, *quam ori infundunt*.

GRANITES, in *Natural History*, are defined to be stones composed of separate and very large concretions, rudely compacted together, so as not to form one mass or solid thing, like marble, but to remain distinct from each other, of great hardness, giving fire with steel, not fermenting with acids, and slowly calcining in a strong fire.

The parts of which the *granites* consist are not homogeneous, but are composed of common quartz, feltspar or rhomboidal quartz, and of mica, with which are also often accidentally mixed particles of other stones and metallic earths. From this granulose structure, they derive their name *granites*, i. e. *granis compositus*. Some writers in mineralogy have injudiciously made the *granite* either a variety or species of the PORPHYRY; and others have given the name of *granites* to all marbles variegated with red, black, yellow, &c. spots, merely on account of their being speckled marbles.

The species of this genus are the following: 1. The *granite* with a black ground, having a slight tincture of green spotted with white: nodules of this are frequent on most of our English shores, and large masses of it abound in the pavements of the streets of London. 2. The black and white *granite*, called *moor-stone*. 3. The *granite* with a dusky white ground, irregularly and thickly sported with small black spots: this stone takes a very fine polish and surface; it is called by the Italians *granitello*, and by modern travellers the *grey granite*: there are great quantities of it found in the ancient temples and other buildings of Egypt, Asia, and Italy; and there is scarce an island in the Archipelago that does not abound with it: the most common *granite* of Europe is of this species; there are large quarries of it in the provinces of Normandy and Provence in France, where it is used for door-cases and chimney-pieces. 4. The white *granite*, with a few black spots, found in nodules and masses on many of the shores of Europe. 5. The white *granite* with large green spots: this is a beautiful species, and takes a fine polish and surface: there are strata or masses of this *granite* in the county of Downe in Ireland, especially about Newry, which town is partly built with this stone. 6. The red, black, and white *granite*, commonly known by the name of oriental *granite*.

The oriental *granite* of the moderns is the stone described by the ancients under the name of *porphyrites* and *syenites*, and from its extreme hardness and beauty has been always greatly esteemed. It is, when in its rough state, a very rude, coarse, and irregular mass, but of a very firm and compact structure, and is of a very beautiful pale red, variegated with white and black; the red parts are of an irregular structure and marbly appearance. The white are tabular, or composed of flat concretions, and many of them are very bright and pellucid, others of rough surfaces and semi-opake; the former are composed of a talcy, the latter of an earthy crystal. The black parts are plainly foliaceous, and are composed of a black crystalline talc. And beside these, there are, in different parts of the stone, many flakes both of black and white unaltered talc. The whole is of a very singular hardness, but takes an extremely elegant and beautiful polish.

There are many varieties of this oriental *granite*: the true oriental red *granite*, of which the temples, obelisks, and other ancient buildings that abound in Egypt, Asia, and Italy, were built, was procured from Upper Egypt, and particularly from Syene in the Thebais; the quarries in this place have been described by Dr. Pococke, in his Description of the East, vol. i. p. 137. The whole country of Arabia Petræa is a mass of *granites*; and this red *granite* is also found in many parts of Europe: there are many fine tables, &c. equal to the finest oriental *granite*, at mount Edgcumbe in Devonshire, which have been wrought from stone found in those parts. Masses of this stone are likewise found in many other counties of England. The whitish red *granite*, which is sometimes found in large strata, but more frequently in large loose nodules, is a variety of the same species. It is very plentiful in many parts of the island of Minorca, from whence we might have it in abundance, and it would make very beautiful tables, &c. The rough masses of it are sometimes found also on the shores of our island of Guernsey, whence they are taken up for ballast for ships, and are sometimes by this means brought among us, and used in the pavements of our streets.

7. The *granite* of a pale yellowish colour, spotted with small irregular black spots: this is a rare species; but some nodules of it are found in the county of Donnegal, in Ireland; and there are pillars of it at Constantinople, and a colossal statue twelve feet high near Thebes in Upper Egypt, mentioned by Pococke ubi supra, p. 103. 8. The *granite* of a fine grass-green colour, thickly spotted with black: this is a rare but elegant stone; small nodules of it are sometimes found on our shores; and *granite* of this species is also dug near Sienna in Italy. Hill's Foss. p. 468, &c. Mem. da Costa's Foss. p. 273, &c.

GRANIVOROUS, an epithet or denomination given to such animals as feed upon corn, or any other grain or seeds.

Granivorous animals are chiefly of the BIRD kind. These have a peculiar provision for the digesting of so dry and hard a food.

GRANT, in *Law*, a gift in writing of something incorporeal, not lying in livery, and which cannot aptly be passed or conveyed by word only; as rents, reversions, services, advowsons in gross, cyphes, &c.

Or, it is a gift made by such person as cannot give but by deed; as the king, and all bodies politic. See DONATION.

This difference is often, in speech, neglected; and the word *grant* taken generally for any gift whatsoever, made of any thing, by any person.

In this ſenſe, he that granteth is named *grantor*; and he to whom it is made, the *grantee*.

A thing is ſaid to lie in *grant*, which cannot be aſſigned without deed.

GRANULATED *oil*. See OIL.

GRANULATION, in *Chemiſtry*, an operation performed on metals, whereby they are reduced into ſmall grains or globules.

It is done by melting them, and when in fuſion, caſting them from a certain height into cold water; in which they congeal into granules, as required, and are hereby rendered more eaſy to be diſſolved. The beſt way is to pour the fluid metal through a colander, or a new birchen broom, or to agitate the water with the broom, thus giving it a circular motion whilſt the metal is poured in. Copper is *granulated* for making BRASS in a cylindrical wooden reſervoir, four or five feet deep, in which a circular braſs or copper bottom may be raiſed or lowered by means of a chain. The reſervoir is covered with a copper lid, in the middle of which is a hole half a foot in diameter, intended to receive an iron laddle pierced with holes and coated with clay. The reſervoir being filled with water, the melted copper is poured through the holes in the laddle into the water; where it is broken by its fall into ſmaller drops or grains, rendered ſolid by the cold water, and collected in the moveable bottom, which is raiſed by the armered chain, that the *granulated* copper may be taken out. Marquer, Dict. Chem. Eng. edit. art. *Braſs*.

Lead, tin, and braſs, which are very brittle, when they are ſo hot as to be almoſt fuſed, may be *granulated* by pouring them, in a ſtate of fuſion, into a box, the inner ſurface of which is rubbed with powdered chalk, and by ſhaking the box: the metals in the box are no ſooner become ſolid, and conſequently very brittle, than they are ſhivered, by being daſhed againſt the ſides of the veſſel into a fine duſt. Silver and gold, and the more tenacious metals, muſt be *granulated* in either of the firſt methods above mentioned with water. Cramer, Art of Aſſ. p. 70.

The term *granulation* is alſo applied to GUN-*powder*.

GRANULOSE *roots* are thoſe compoſed of ſmaller knobs than the grumoſe ones, and reſembling ſo many grains of corn; of this ſort is the white ſaxifrage

GRANUM *viride*, in *Botany*, a name given by ſome authors to the turpentine-tree. The fruit of this tree is reddiſh while unripe; but as it ripens, it becomes of a deep bluiſh green colour, and hence the name.

GRAPE, the fruit of the vine. See VINE and WINE. See alſo CURRANTS and RAISINS.

GRAPE *hyacinth*. See HYACINTH.

GRAPE, *mangrove* or *ſea-ſide*, *coccoloba*, a genus of the *octandria trigynia* claſs. Its characters are theſe: the flower has one permanent petal, which is cut into five ſegments; it has a fleſhy umbilical nectarium which ſurrounds the germen, and ſix, ſeven, or more erect ſpreading ſtamina, with an oval germen, which turns to a fleſhy berry, including an oval nut, which is wrapped up in the petal of the flower. There are ſix ſpecies, natives of the Weſt Indies, where growing on the ſea-ſhore, they have obtained the name of *ſea-ſide grapes*.

The leaves of theſe plants continuing in verdure all the year, make a fine appearance in the hot-houſe in winter; but they do not produce flowers here.

They muſt be propagated by ſeeds, ſown in pots of light rich earth, and plunged into a hot-bed of tanner's bark: the plant muſt conſtantly remain in a ſtove, being too tender to live in the open air, even in our warmeſt weather; only in ſummer they may be frequently refreſhed with water, and have freſh air admitted to them. Miller.

GRAPE, *wild*. See LAVOUTABULLE.

GRAPE-*galls*, in *Natural Hiſtory*, a name given by authors to a ſpecies of preternaturaces reſembling cluſters of *grapes*, and when ripe of a reddiſh colour, which are found hanging from the oak at ſome ſeaſons of the year. Theſe are genuine galls, though of a peculiar kind, and owe their origin to a very ſmall four-winged black fly. This little creature depoſits its eggs either on the ſurface, or within the ſubſtance of thoſe pedicles of the oak which nature has deſtined for producing the catkins or ſmall flowers of that tree. The biting and ſucking of the worms, which are produced from theſe, occaſion a wrong derivation of the juices to the part; and the conſequence of this is, that, inſtead of flowers, there appears a protuberance over the part where each of theſe inſects is lodged. This tubercle at firſt is ſmall, and of a pale greeniſh colour; but it ſhortly becomes yelloweſh or reddiſh, and is juicy and large. A number of theſe ſtanding cloſe together upon the ſtalk, give the appearance of a cluſter of *grapes* on the bunch; and when any one of theſe is opened, there is found in it either a worm, a chryſalis, or a fly, the animal never quitting its habitation till in its perfect ſtate, but paſſing through all its changes in it. Reaumur, Hiſt. Inſect. vol. vi. p. 18.

GRAPE-*ſhot*, in *Artillery*, is a combination of ſmall ſhot, put into a thick canvas bag, and corded ſtrongly together, ſo as to form a kind of cylinder, whoſe diameter is equal to that of the ball adapted to the cannon. The number of ſhot in a *grape* varies according to the ſervice or ſize of the guns: in ſea-ſervice nine is always the number; but by land it is increaſed to any number or ſize, from an ounce and a quarter in weight to three or four pounds. In ſea-ſervice the bottoms and pins are made of iron, whereas thoſe uſed by land are of wood.

GRAPES, in the *Manege*, a term uſed to ſignify the ARRETS or mangy tumours that happen in a horſe's legs.

GRAPHICAL, *perſpective*, in *Optics*, is an inſtrument deſcribed by Mr. Martin, conſiſting of a tube containing two convex lenſes, which are placed at twice their focal diſtance from each other; and in their common focus is another glaſs, divided into equal parts with the point of a diamond. Though this inſtrument does not magniſy any object, yet the angle under which an object is ſeen is eaſily known by it; and ſince this angle varies with the diſtance of objects, it is eaſily applied to the purpoſe of meaſuring inacceſſible heights and diſtances; and ſince the field of view is divided into equal ſquares, it is uſeful in drawing the perſpective appearance of objects. Moreover, as all foreign light is excluded by the tube in which theſe lenſes are incloſed, pictures ſeen through it have a fine relievo, on which account, and alſo becauſe objects appear inverted through it, the images of a CAMERA *obſcura* are viewed with it to peculiar advantage. If a lens of a greater focal length be fixed at a proper diſtance from the centre of the tube, this inſtrument will be a teleſcope, and will magnify the points which are looked at through it; and if a ſmall lens be uſed, it will be a microſcope, and the ſame micrometer will ſerve for them both. Martin's Optics, chap. xvii. p. 280, &c.

GRAPHIDA, in *Natural Hiſtory*, a name by which ſome authors have called the MOROCTHUS, or French chalk.

GRAPHISCUS, in the *Writings of the Ancients*, a name given to an inſtrument uſed for extracting darts from wounds. It is ſaid to have been the invention of Diocles, and is deſcribed by Celſus.

GRAPHOIDES, or GRAPHIOIDES, *γραφοειδης*, in *Anatomy*, an appendage of the bones of the temples, long, ſmall, ſharp, and a little crooked, like a cock's ſpur; called alſo *ſtyloides*.

The ſame name is ſometimes alſo applied to the muſculus digaſtricus.

Likewiſe to an extenſion of the brain, reſembling a writing pen.

GRAPHOMETER, a name which ſome authors, particularly the French, give to a ſurveying inſtrument, by us commonly called a SEMICIRCLE.

GRAPLINGS, in a *Ship*. See GRAPNEL.

GRAPNEL, or GRAPPLING, on *Ship-board*, a kind of ſmall anchor for boats or gallies to ride by. It differs from other anchors, as having four or five flukes and no ſhank, though there are ſome with three flukes, with which they uſe to ſweep for hawſers or ſmall cables. In men of war alſo, the *grapnels*, or at leaſt a lighter kind of them, whoſe flukes are furniſhed with ſtrong barbs on their points, are uſed to be thrown into an enemy's ſhip, in order to catch hold of ſome of her gratings, rails, gun-wales, &c. this is done in order to boarding of her. They are particularly uſeful in FIRE-*ſhips*, and called *fire-graplings*.

GRAPPLE, in the *Manege*. A horſe is ſaid to *grapple* with one or both legs, when he catches or raiſes them more haſtily and higher than ordinary, as if he were cutting.

GRASS, *gramen*, in *Botany*. To enumerate all the ſpecies of graſs which are found growing naturally in England, would greatly exceed the bounds which can be allowed for this article; it will ſuffice, therefore, to mention a few ſpecies, which are either uſed in medicine, or cultivated as a pabulum for cattle; for there is ſcarcely a paſture in this country where great numbers of different ſpecies are not to be found intermixed. Mr. Ray has ranged them in the following order, *viz.* wheat-*graſs*, rye-*graſs*, darnel-*graſs*, panick-*graſs*, canary-*graſs*, foxtail-*graſs*, cat's-tail-*graſs*, hedge-hog-*graſs*, creſted-*graſs*, cat-*graſs*, cock's-foot-*graſs*, buck-*graſs*, and millet-*graſs*. Theſe and other *graſſes* Linnæus has arranged into diſtinct genera.

The common creeping *graſs* with a ſpike like wheat, called dog or couch-*graſs*, which is a ſpecies of the TRITICUM in the Linnæan ſyſtem, has a creeping root which ſpreads far in the ground, and is a very troubleſome weed in gardens and arable land. The common method of deſtroying it in the former, is to fork out the roots as often

often as the blade appears above ground; where this is two or three times carefully repeated, it may be totally rooted out: but when the furface of the ground is very full of the roots of this *graſs*, the ſhorteſt way of deſtroying it is to trench the ground two ſpits and a ſhovelling deep, turning all the couch to the bottom, where it will rot and, never ſhoot up; but in ſhallow ſoils, the roots cannot be buried ſo deep as to lie below the depths at which they naturally ſhoot.

Where the roots of this *graſs* get poſſeſſion of arable fields, the uſual method of eradicating it is by laying the land fallow in ſummer, and frequently harrowing it well to draw out the roots: where this is carefully practiſed, the ground may be ſo well cleaned in one ſummer, that the roots cannot much injure the crop which may be ſown upon it; but ſuch land ſhould be ſown with articles which require the hoe-hoeing culture; for where the land can be frequently ſtirred or harrowed afterward, it will be of great ſervice in cleaning it from the roots of this *graſs* and other bad weeds. The blade of this *graſs* is ſo rough that cattle will not feed upon it.

The roots of this couch-*graſs* are uſed in medicine, and are accounted aperitive and diuretic, opening obſtructions in the reins and bladder, promoting urine, and are of ſervice againſt the gravel and ſtone. The juice of the leaves and ſtalks was greatly eſteemed by Dr. Boerhaave, who generally preſcribed it in all caſes where he ſuppoſed there were any obſtructions in the biliary ducts.

The darnel with a chaffy ſpike, commonly called ray or rye-*graſs*, which is a ſpecies of the LOLIUM in the Linnæan ſyſtem, is a hairy ſort of *graſs*, much eſteemed among the farmers for that quality. It will grow on any land, and therefore produces crops where nothing elſe will. It thrives beſt of all on ſoar, clayey, and weeping grounds, and equally endures the ſevereſt droughts of ſummer, and froſts of winter, ſuffering no damage from either. It is the beſt of all winter foods for cattle, the ſhorter it is eaten the better, and it ſprings the earlieſt of any. There is no danger of overſtocking it, for if it be left to grow too much, the ſtalk becomes hard and ſtiff. It is beſt for horſes and for ſheep, and very much prevents the rotting of the latter. The beſt way of ſowing it is with clover. The common quantity of ſeed is two buſhels to an acre, but three buſhels are much better; though in ſome lands, where the clover is likely to ſucceed very well, they ſow eight pounds of clover-ſeed, and one or two buſhels of rye-ſeed to an acre, and this makes a crop that will laſt ſeven or eight years. The ſpecies of *graſs* uſually cultivated in this manner is called the red darnel.

Some mow it as hay, and threſh it for the ſeed, which, about London, ſells from half a crown a buſhel to three ſhillings. Four or five quarters of this ſeed will be ſometimes produced from an acre of the *graſs*. If at any time a field of this *graſs* is found to grow thin, it is only neceſſary to ſtrew on a buſhel of the ſeed, and roll it with a wooden roller, and the plants ariſing from this addition will make the whole crop ſufficiently full. Rye-*graſs* has this great advantage, that it kills weeds without any other ſown plant; even thiſtles cannot grow among it. When the rye-*graſs* is cut for hay before it is perfectly ripe, the hay is the better, but the ſeed will not grow ſo well. When the ſeed is newly threſhed, it muſt not be laid too thick, for it is very apt to heat and ferment, and the whole will be ſpoiled. Mortimer's Huſbandry, p. 40.

The meadow *graſs* with large panicles and a narrow leaf, and that ſort with a broad leaf, which are ſpecies of the POA in the Linnæan ſyſtem, are the two beſt ſpecies of *graſs* for paſtures; ſo that if the ſeeds of theſe were carefully collected and ſown ſeparately, without any other mixture of *graſs*, there would not only be a greater quantity of feed on the ſame ſpace of land, but the *graſs* would be better, the hay ſweeter, and the verdure more laſting than any other ſort; but there requires ſome attention to the ſaving the ſeed pure without mixture.

The taller meadow oat-*graſs* with a yellowiſh panicle and ſmall huſks, which is a ſpecies of the AVENA of Linnæus, and the tall meadow rye-*graſs*, are alſo very good *graſſes* for paſtures, and have perennial roots. Theſe are a very leafy kind of *graſs*, and their ſtalks do not become ſtiff and ſtrift, like thoſe of ſome other ſpecies; but with proper care may be made very fine, and if daily rolled, the roots will mat and form a very cloſe ſward. The greateſt quaking *graſs*, or cow-quakes, is mentioned for variety, not for uſe; this has an annual root. The heads hang by long ſlender foot-ſtalks, which being moved by every wind, they generally appear ſhaking, and gained it the title of quaking *graſs*. See BRIZA.

The cock's foot-*graſs*, cupon's tail-*graſs*, and millet *graſſes*, are too coarſe to deſerve attention in England.

The land upon which *graſs* is intended to be ſown, ſhould be well ploughed and cleared from the roots of noxious weeds, eſpecially if the *graſs* is to remain for paſture. Therefore, in places where weeds abound, it will be a good method to plough up the ſurface in April, and let it lie ſome time to dry; and then harrow the roots into ſmall heaps and burn them. The aſhes ſo produced will be good manure for the land when ſpread upon it: but when couch, fern, or reſt harrow is in plenty, whoſe roots run ſo under ground, the land ſhould be ploughed two or three times, ſomewhat deep, in dry weather, and the roots be carefully harrowed off after each ploughing, which is the moſt ſure way to deſtroy them. Where the land is very low, and of a ſtiff clayey nature, which holds water in winter, it will be of ſingular ſervice to make ſome under-ground drains to carry off the wet, which, if long detained on the ground, will render the *graſs* ſour.

Before the ſeed is ſown, the ſurface of the ground ſhould be made fine and level, and the ſeed ſhould be harrowed in, and the ground rolled with a wooden roller. When the *graſs* comes up, if there ſhould be any bare ſpots they may be ſown again, and the firſt kind flowers will bring up the *graſs* and make it very thick. Miller.

GRASS, *arrow-headed*. See TRIGLOCHIN.

GRASS, *bent*. See AGROSTIS.

GRASS, *bird*. See BIRD-*graſs*.

GRASS, *canary*, in *Botany*. See PHALARIS.

GRASS, *cat's-tail*. See FESTUCA.

GRASS, *cat's-tail*. See PILULARIA.

GRASS, *cocks*. See TRIFOLIUM.

GRASS, *cock's-foot, ſtalkleſs*, a genus of the *triandria digynia* claſs: the calyx of which is compreſſed and bivalve.

GRASS, *ettum*. See ERIOPHORUM.

GRASS, *couch*. See GRASS ſupra.

GRASS, *creſted*. See DOG'S-*tail*.

GRASS *dog's*. See GRASS ſupra.

GRASS, *fearing's*, a name ſometimes given to the double ſpiked fecale or rye. See RYE.

GRASS, *dog's-tail*. See DOG'S-*tail*.

GRASS, *feſcue*. See FESTUCA.

GRASS, *fox-tail, alopecurus*, in *Botany*, a genus of the *triandria digynia* claſs. Its characters are theſe: the calyx is a glume compoſed of two valves, and incloſing a ſingle flower; theſe valves are oval-pointed and hollow; the flower is compoſed only of one valve, which is hollow, and of the ſame length with the calyx, and has a long awn or beard inſerted on its back part near its baſis; the ſtamina are three capillary filaments; the antheræ are oblong; the germen of the piſtil is roundiſh; the ſtyles are two in number, hairy, reflex, and exceed the length of the cup; the ſtigmata are ſimple; and the flower incloſes the ſeed, which is ſingle and roundiſh.

GRASS, *goſe*. See ASPERUGO.

GRASS, *hair, aira*, a genus of the *triandria digynia* claſs. The calyx is of two valves, incloſing a double flower, and the boſculi have no ſeparating rudiment.

GRASS, *hare's-tail, lagurus*, a genus of the *triandria digynia* claſs. The calyx is compoſed of two valves, with a downy beard.

GRASS, *knot*, in *Botany*, a name given to ſeveral diſtinct genera of plants. See KNOT-*graſs*.

GRASS, *knot, or quaking* GRASS. See ſupra.

GRASS, *meadow*. See GRASS ſupra.

GRASS, *hard meadow*. See DOG'S-*tail*.

GRASS, *millet*. See MILLET.

GRASS, *oat*, a name given to a ſpecies of the FESTUCA.

GRASS, *panic*. See PANIC.

GRASS, *of Parnaſſus, Parnaſſia*, in *Botany*, a genus of the *pentandria tetragynia* claſs. Its characters are theſe: the flower has a ſpreading empalement, cut into five parts, and has five roundiſh concave petals, which have five heart-ſhaped concave nectariums, and five ſtamina terminated by depreſſed ſummits, with a large oval germen having no ſtyle, but four obtuſe ſtigmas in their place; the germen turns to an oval four-cornered capſule, with one cell, containing ſeveral oblong ſeeds. There are two ſpecies.

GRASS, *pepper*. See PILULARIA.

GRASS, *pudding*, a name ſometimes given to PENNY-ROYAL.

GRASS, *quaking*. See GRASS ſupra, and BRIZA.

GRASS, *rattle*. See LOUSE-*wort*.

GRASS, *ruſh*. See RUSH.

GRASS, *rye*. See GRASS and LOLIUM.

GRASS, *ſcorpion*. See CATERPILLAR.

GRASS, *ſwing*. See SCURVY-*graſs*.

GRASS, *ſhave*. See HORSE-*tail*.

GRASS, *ſilk*. See ALOE and DOG'S-*bane*.

GRASS, *ſword*. See *Corn*-FLAG.

GRASS, *treſoil*. See TREFOIL.

GRASS, *vernal*. See ANTHOXANTHUM.

GRASS, *vetch*. See *Chickling* VETCH.

GRASS, *viper's*. See VIPER'S-*grass*.
GRASS, *whitlow*. See DRABA.
GRASS, *worm*. See SPIGELIA.
GRASS, *wrack*. See ZOSTERA.
See alſo for other kinds, under LUCERN and SAINTFOIN.

GRASS-*plats* and *walks* make a conſiderable article in *Gardening*, our turf being, like our gravel, ſuperior to that of any other country.

The common way of making theſe is by laying on turfs from a common, and the plats thus made are greatly ſuperior to thoſe made by ſowing, there being great nicety and art required in bringing the latter to good order, and in procuring the proper ſeed, that from common hay-lofts being of a mixture of good and bad kinds, and by no means fit for the purpoſe, as containing the ſeeds of weeds, as well as very improper *graſſes*.

If the ſoil be dry, it is beſt to lay theſe quite even and level; but if damp, they may be laid a little rounding, but not more than an inch in twenty feet. If the ſoil is rich, the ſurface of the ground under the turf ſhould be covered with ſand or poor earth, which will keep the *graſs* fine. The oftener theſe walks are mowed and rolled in ſummer, the thicker their bottoms will be, and in autumn they ſhould be kept ſhorter than at any other ſeaſon, for if the blade runs up high at that ſeaſon, the bottom will be bare in winter. All *graſs*-walks ought alſo to be frequently rolled, as the gardeners call it: this operation is diſperſing the worm-caſts all over the walks with long aſh poles; this, beſide deſtroying the worm-caſts, is very beneficial to the *graſs* of the walk. When turf is deſigned to remain for years without renewing, a dreſſing of rotten dung, aſhes, or rotten tan, ſhould be laid upon it every other year; and theſe dreſſings ſhould be laid on early in winter.

In order to ſow *graſs*, the ground muſt be dug, then finely and evenly raked over, all the clods and ſtones taken off, and an inch thickneſs of good mould ſifted on it. This done, the ſeed muſt be ſown very thick, that the blade may come up cloſe and ſhort; and the ground muſt be then raked over again, to bury the ſeed, otherwiſe, if it ſhould happen to be windy weather, a great part of it may be blown away.

The beſt ſeaſon for ſowing *graſs* is the latter end of Auguſt, and it is beſt to ſow it in a mild day, when there is a likelihood of rain. When *graſs* is ſown in gardens, for lawns or walks, the ſeed of the beſt paſture-*graſs* ſhould be mingled with a good quantity of the white trefoil or Dutch clover, which will make a finer turf, and continue a better verdure than any other *graſs*. When it is come up to any height it muſt be mowed, and this repeated very frequently, for the oftner it is mowed the thicker it grows. It ſhould be rolled alſo frequently with a wooden roller. In autumn, wherever there are naked patches, the ground ſhould be ſown with freſh ſeed. Miller.

GRASS-*hearth*, in our *Cuſtoms*, *graſing*, or turning up the earth with a plough. Hence the cuſtomary ſervice for the inferior tenants of the manor of Amerſden in Oxfordſhire, to bring their ploughs to do one day's work for their lord, was called *graſs-hearth* or *graſs-hurt*.

GRASSA, a name given by ſome authors to native *borax*.

GRASSETTE, in *Botany*, the name given by the French to the *pinguicula* or butter-wort, called alſo in Yorkſhire SANICLE.

GRASSHOPPER, a ſpecies of GRYLLUS. See LOCUST.

GRATICULATION, a term ſome writers uſe for the dividing a draught or deſign into ſquares, in order to the reducing it thereby.

GRATINGS, in a *Ship*, are ſmall ledges of ſawed plank, framed one into another like a lattice or priſon grate, lying on the upper deck, between the main-maſt and fore-maſt, ſerving for a defence in a cloſe fight, and alſo for the coolneſs, light, and convenience of the ſhip's company.

GRATIOLA, in *Botany*. See *Hedge* HYSSOP.

GRATITUDE, in *Ethics*, a virtue diſpoſing the mind to an inward ſenſe and outward acknowlegement of benefits received.

GRAVE, in *Grammar*, a ſpecies of accent oppoſite to acute. The grave accent is expreſſed thus, (`); and ſhews, that the voice is to be depreſſed, and the ſyllable over which it is placed, pronounced in a low, deep tone.

GRAVE, in *Muſic*, is applied to a ſound which is in a low or deep tone.

The thicker the chord or ſtring, the more *grave* the tone or note, and the ſmaller the acuter.

Notes are ſuppoſed to be the more *grave*, in proportion as the vibrations of the chord are leſs quick. See GRAVITY, in *Muſic*.

GRAVE, in the *Italian Muſic*, ſerves to denote the ſloweſt movement. See TIME.

GRAVE is alſo an ingredient in the compoſition of divers *terms in* hiſtory and poeſy. Thus we ſay LAND-*grave*, BURG-*grave*, MARG-*grave*, PAL-*grave*, &c.

The word, in this ſenſe, is formed of the German *graf*, ſignifying *comes*, *count*; called in the barbarous Latin *gravio* and *graphio*.

GRAVE is alſo uſed for a tomb, wherein a perſon defunct is interred.

GRAVEDO, a heavineſs or ſtifneſs which accompanies a leſſened tranſpiration or taking cold, as it is commonly called. Hence, alſo, the caſe being frequently accompanied with a running of the noſe and eyes, *gravedo* and CORYZA are ſometimes uſed promiſcuouſly. See CATARRH.

The ſigns of a *gravedo* are a dizzineſs and heavineſs of the head, attended with tenſive and preſſing pains, which ſometimes become violently pungent, and, as it were, burning, a remarkable turgeſcence of the veſſels, thirſt, and a dryneſs of the mouth, and unſound ſleep; and finally, the breaſt is drawn into conſent, and is afflicted with a tenſive and oppreſſive pain.

The *gravedo* is a ſpecies, or rather ſymptom, of the HEAD-ACH, and conſequently is removed by the ſame means.

GRAVEL, in *Natural Hiſtory*, coarſer ſand, found at the bottom and the ſides of rivers.

The word is formed of the French *gravier*, which Du-Cange derives from the barbarous Latin *gravarium*, ſignifying the ſame.

Monſ. Perrault and Dr. Woodward lay down the difference between ſand and *gravel*. The firſt is ſmall, and conſiſts of finer evener grains; the latter is bigger, and conſiſts of little pebbles and flints of various kinds, and mixed with the ſand and the finer fragments of other ſtones.

Gravel is chiefly uſed in laying yards, courts, and walks, in gardens.

The *gravel* of England as much excels that of France, Holland, Flanders, &c. as the graſs does. This and graſs are the natural ornaments of a country-ſeat. We have ſeveral ſorts of *gravel* in the different parts of England, but that which is common on Black-heath is the moſt valuable ſort for garden-walks, as it conſiſts of round, even, and beautiful pebbles, and when mixed with a ſtiff loam, binds well, and keeps in order the longeſt of all kinds of *gravel*.

GRAVEL-*bind*, in *Botany*. See CONVOLVULUS.

GRAVEL-*walks*. Theſe are deſervedly eſteemed a great advantage, which our gardens have over thoſe of all other nations. The method of laying ſuch walks is this:

The bottom ſhould be laid with lime rubbiſh, or large flint ſtones, or any other hard matter, for eight or ten inches thick, to keep weeds from growing through, and over this the *gravel* is to be laid about ſix or eight inches thick: this ſhould be laid rounding up in the middle, by which means the larger ſtones will run off to the ſides, and may be raked away, for the *gravel* ſhould never be ſcreened before it is uſed. The moſt proper time for laying *gravel* is the month of March, and they ſhould alſo be turned at this time, and not laid up in ridges in December, which is a frequent but injurious practice. It is a common miſtake to lay theſe walks too round, which not only makes them the more uneaſy to walk on, but takes off from their apparent breadth. One inch in five feet is a ſufficient proportion for the riſe in the middle, ſo that a walk of twenty feet wide ſhould be four inches higher in the middle than at the edges, and ſo in proportion. As ſoon as the *gravel* is laid it ſhould be raked, and the large ſtones thrown back again; then the whole ſhould be rolled both lengthwiſe and croſswiſe, and the perſon who draws the roller ſhould wear ſhoes with flat heels, that he may make no holes, becauſe holes made in a new walk are not eaſily remedied. The walks ſhould always be rolled three or four times in very hard ſhowers, after which they will bind more firmly than they could ever be made otherwiſe to do.

In making *gravel*-walks, regard ſhould be paid to the level of the ground, ſo that they may be laid with eaſy deſcents to the lower parts, in order to drain off the moiſture; and where there are no declivities, it will be proper to have ſink-ſtones laid, at convenient diſtances, by the ſides of the walks: in dry ground, the water may be conveyed from hence into ſoſs-pools, and thus ſunk away; but in wet land, there ſhould be under-ground drains, for conveying the water to the neareſt pond or ditch.

Gravel, with ſome loam among it, binds much more firmly than the rawer kinds, and when *gravel* is naturally very harſh and ſharp, it is very proper to add a mixture of loam to it. The beſt *gravel* for walks is ſuch as abounds with ſmooth round pebbles, which being mixed with a little loam, binds ſo firmly, as never to be injured after, either by wet or dry weather. Theſe are not ſo

liable to be turned up by the feet in walking, as the more irregular-shaped pebbles, and remain much more firmly in their places after rolling. Miller.

Note, the sides next the beds should be laid a foot and a half thick, or two feet, with turf, from whence the heat of the sun cannot be reflected as it is from gravel, to the prejudice of the neighbouring flowers.

GRAVEL, in *Medicine*, a disease of the bladder and kidneys, occasioned by a sandy or gritty matter gathered therein, which coheting into a stony mass, prevents the due secretion and excretion of the urine.

The *gravel* is generally considered as the same disease with the calculus or stone.

The causes and symptoms of the *gravel* and stone are much the same, and they require a similar treatment, both with regard to regimen and medicine. See STONE.

GRAVELLING, among *Farriers*, a disorder incident to travelling horses, occasioned by little gravel-stones getting in between the hoof and the shoe, which, setting to the quick, fret and fester the part.

It is cured by pulling off the *shoe*, drawing the place to the quick, picking out all the gravel, and stopping up the foot with horse-grease and turpentine poured in hot.

GRAVELLY *soil*. See SOIL.

GRAVER, a steel instrument, serving to engrave on metals.

The *graver* consists of *four sides* or faces, and the point usually terminates in a lozenge: in some it is round, and in others square. The round point is best for flowing lines, the square for cutting broad and deep, and the lozenge for more delicate and fine strokes and scratches. Le Bosse recommends those of a form betwixt the square and lozenge. See ENGRAVING.

The *gravers* should be made of the best steel, which must be drawn out into small rods with a charcoal fire. These rods, after having been cut into the proper lengths for *gravers*, should be softened, by heating them in a charcoal fire, and suffering them to cool very slowly: let them next be filed into the desired form, and brought back to a hard temper by heating them red-hot, and in this state dipping their ends into soft soap. This should be done in a perpendicular direction; for, if they be turned in the least degree obliquely, the *graver* will warp and be crooked. If the temper of the *graver* be too hard after this treatment, and prevent the whetting it properly to an edge, it may be softened, by laying its end on a large burning piece of charcoal till it begins to grow yellow, and then thrusting it into a lump of tallow, or dipping it in water; but if water be used, the *graver* must not be too hot. It may be known whether the *graver* be tempered to a proper hardness by touching the edge of it with a file, which, if any effect attends it, proves the temper to be too soft. The best proof of too great hardness is the breaking of the point in engraving; after which, if a new edge be made by whetting the *graver*, it will be frequently found very good without any other alteration. Handmaid to the Arts, vol. ii. p. 56.

The other end is fitted into a wooden handle.

Besides engravers, the seal-cutters, locksmiths, gunsmiths, goldsmiths, armourers, spurriers, &c. likewise make use of *gravers*.

GRAVING, the act or art of cutting lines, figures, and other designs, on metals; more properly called ENGRAVING.

GRAVING, in the *Sea-Language*, is the bringing a ship aground, and then burning off with furze, reed, or broom, all the filth and foulness that sticks to her bottom without-board, in order to pay her anew. See BROOMING and CAREENING.

GRAVITAS, *Βαρυτης*, in the *Ancient Music*, was used to signify a sound produced by the remission or falling of the voice. *Gravitas* differs from remission, as the effect from the cause.

GRAVITAS is also used to denote the state of a woman going with child. See PREGNANCY.

GRAVITATION, the exercise of gravity, or the pressure a body exerts on another body underneath it by the power of gravity.

It is sometimes distinguished from gravity. Thus Monsieur Maupertuis takes gravity for that force whereby a body would fall to the earth supposed at rest; and *gravitation* for the same, but diminished by the centrifugal force. See Fig. of the Earth determ.. 2. 66. of Mr. Murdoch's translation.

It is only *gravitation*, or gravity thus balanced with the centrifugal force, that we can measure by our experiments. However, methods have been found to distinguish what remains of primitive gravity, and what has been destroyed by the CENTRIFUGAL *force*.

It is one of the laws of nature, discovered by sir Isaac Newton, and now received by most philosophers, that every particle of matter in nature gravitates towards every other particle; which law is the hinge whereon the whole NEWTONIAN *philosophy* turns.

What we call *gravitation*, with respect to the gravitating body, is properly called *attraction* with respect to the body gravitated to.

The planets, both primary and secondary, as also the comets, do all gravitate towards the sun, and toward each other; and the sun toward them; and that in proportion to the quantity of matter in each.

The Peripatetics, &c. hold, that bodies only gravitate when out of their natural places, and that *gravitation* ceases when they are restored to the *same*, the intention of nature being then fulfilled. The final cause of this faculty, they hold, is only to bring elementary bodies to their proper place, where they may rest. But the moderns shew, that bodies exercise gravity even when at rest, and in their proper places.

This is particularly shewn of fluids; and it is one of the laws of hydrostatics, demonstrated by Mr. Boyle, and others, that fluids gravitate *in propria loca*, the upper parts pressing on the lower, &c.

For the laws of *gravitation* of bodies in fluids specifically *lighter* or *heavier* than themselves, see *Supplem.* GRAVITY, FLUID, &c.

GRAVITATION, *centre of*. See CENTRE.

GRAVITATION, *line of*. See LINE.

GRAVITATION, *plane of*. See PLANE.

GRAVITY, in *Physics*, the natural tendency or inclination of bodies towards the centre.

In this sense *gravity* coincides with CENTRIPETAL *force*. *Gravity* is defined by others, more generally, to be the natural tendency of one body towards another; and by others more generally still, the mutual tendency of each body, and each particle of a body, *towards* all others: in which sense the word coincides with what we more usually call ATTRACTION.

The terms *gravity*, centripetal force, weight, and attraction, do, in effect, all denote the same thing, only in different views and relations; which different relations, however, authors are apt to confound, and, accordingly, the four are frequently used promiscuously.

In propriety, when we consider a body as tending towards the earth, the force wherewith it tends we call *gravity*, *force of gravity*, or *gravitating force*; the same force, when we consider it as immediately tending to the centre of the earth, we call *centripetal force*; the *same*, when we consider the earth, or body to which it tends, we call *attraction* or *attractive force*; and when we consider it, in respect of an obstacle or a body in the way of its tendency, upon which it acts, we call it *weight*.

Philosophers conceive very differently of *gravity*; its nature, rise, phenomena, causes, effects, and extent, have afforded various speculations to all ages.

Some consider it as an inseparable property or innate vis in bodies, whereby they endeavour to join their centre. Others hold *gravity* in this sense to be an occult quality, and, as such, to be exploded out of all sound philosophy.

Sir Isaac Newton, though he frequently calls it a vis, power, or property in bodies, yet explains himself, that all he intends by the word is the effect or the phenomenon. He does not consider the principle, the cause whereby bodies tend downwards, but the tendency itself, which is no occult quality, but a sensible phenomenon, be its causes what they will, whether a property essential to body, as some make it, or superadded to it, as others; or even an impulse of some body from without, as others.

It is a law of nature long observed, that all bodies near the earth have a *gravity*, or a tendency towards the centre of the earth; which law the moderns, and particularly the immortal sir Isaac Newton, have found, from certain observation, to be much more extensive, and to hold universally with respect to all known bodies in nature.

It is now, therefore, acknowledged a principle or law of nature, that all bodies, and all the particles of all bodies, *gravitate* towards each other mutually; from which single principle sir Isaac Newton has happily deduced all the great phenomena of nature. See NEWTONIAN *philosophy*.

Hence *gravity* may be distinguished into *particular* and *general*.

GRAVITY, *particular*, is that whereby heavy bodies descend towards the centre of the EARTH.

Phenomena or properties of particular GRAVITY. 1. All circumterrestrial bodies do hereby tend towards a point, which is either accurately or very nearly the centre of magnitude of the terraqueous globe; not as if there was really any virtue or charm in the point called the centre, by which it attracted bodies; but because this is the result of the gravitation of bodies towards all the parts of which the earth consists.

2. The

2. This point or centre is fixed within the earth, or, at least, hath been so ever since we have had any authentic history: for a consequence of its shifting, though ever so little, would be the overflowing of the low lands, on that side of the globe towards which it approached. Dr. Halley suggests, it would well account for the universal deluge, to have the centre of gravitation removed for a time towards the middle of the then inhabited world; for the change of place but the 200th part of the radius of our earth, would be sufficient to lay the tops of the highest hills under water. See DELUGE.

3. In all places which are equidistant from the centre of the earth, the force of *gravity* is nearly equal. Indeed, all places of the earth's surface are not at equal distances from the centre, because the equatorial parts are something higher than the polar parts; the difference between the earth's diameter and axis being about thirty-four English miles, which hath been proved by the necessity of making the pendulum shorter in those places, before it will swing seconds. See *Figure of the* EARTH.

4. *Gravity* equally affects all bodies, without regard either to their bulk, figure, or matter: so that, abstracting from the resistance of the medium, the most compact and loose, the greatest and smallest bodies would descend equal spaces in equal times, as appears from the quick descent of very light bodies in an exhausted receiver.

Hence, a very great difference may be observed between *gravity* and magnetism; the latter affecting only iron, and that towards its poles; the former all bodies alike, and that in every part.

Hence it follows, that *gravity*, in all bodies, is proportionable to their quantity of matter; so that all bodies consist of matter equally heavy.

Hence also may be concluded, that there is no such thing as positive levity: those things which appear light being only comparatively so.

If several things ascend and swim in fluids, it is only because they are not, bulk for bulk, so heavy as those fluids; nor is there any reason why cork, for instance, should be said to be light, because it swims in water, any more than iron, because it will swim on mercury.

5. This power increases as we descend to, and decreases as we ascend from the surface of the earth, and that in the proportion of the squares of the distances from the centre reciprocally; so as, for instance, at a double distance, to have but a quarter of the force, &c. Thus, a body, which, on the earth's surface, or at the distance of one semi-diameter from the centre, weighs 3600, will, at the distance of two, three, four, &c. semi-diameters, weigh 900, 400, 225, &c. pounds respectively. But this power decreases below the surface of the earth in the simple proportion of the distances from the centre.

This proposition may be expressed more generally thus: the weights of the same bodies, at different distances from the centre of the earth, above the surface, are reciprocally as the squares of the distances; and below the surface, directly as the distances from the centre: and therefore, at the surface, their *gravity* is the greatest.

6. As all bodies gravitate towards the earth, so does the earth equally gravitate towards all bodies, i. e. the action of *gravity* is mutual on each side, and equal. See REACTION.

Hence also the attractive powers of bodies, at equal distances from the centre, are as the quantities of matter in the bodies.

Hence also it appears, that the attractive force of the entire bodies consists of the attractive forces of the parts; for, by the adding or taking away any part of the matter of a body, its *gravity* is increased or diminished in the proportion of the quantity of such particle to the entire mass.

GRAVITY, *general* or *universal*. The existence of the same principle of *gravity* in the superior regions of the heavens, as well as on earth, is easily proved.

That all motion is naturally rectilinear is allowed by all: those bodies, therefore, which move in curves, must be retained therein by some power continually acting on them.

Hence, the planets being found to revolve in curvilinear orbits, we infer that there is some power, by whose constant influence they are prevented from flying off in tangents.

Again, it is proved by mathematicians, that all bodies moving in any curve line described in a plane, and which, by radii drawn to any certain point, describe areas about the point proportionable to the times, are impelled, or acted on, by some power tending towards that point: now it is shewn by the astronomers, that the primary planets round the sun, and the secondary planets round the primary ones, do describe areas proportionable to the times. Consequently the power whereby they are retained in their orbits, is directed towards the bodies placed in the centres thereof.

Lastly, it is demonstrated, that if several bodies revolve with an equable motion in several concentrical circles, and the squares of their periodical times be as the cubes of the distances from the common centre, the centripetal forces of the revolving bodies will be reciprocally as the squares of the distances. Or, if bodies revolve in orbits approaching to circles, and the apsides of those orbits be at rest, the centripetal forces of the revolving bodies will be reciprocally as the squares of the distances.

Now, the astronomers all agree, that both these cases obtain in all the PLANETS: whence it follows, that the centripetal powers of all the planets are reciprocally as the squares of the distances from the centres of the orbits.

Upon the whole, it appears, that the planets are retained in their orbits by some power which is continually acting on them: that this power is directed toward the centre of their orbits: that the intension or efficacy of this power increases upon an approach towards the centre, and diminishes at its recess from the same; and that it increases in the same proportion as the distance diminishes; and diminishes in the same as the distance increases. Now by comparing this centripetal force of the planets with the force of *gravity* on earth, they will be found perfectly alike.

This we shall illustrate in the case of the moon, the nearest to us of all the planets. The rectilinear spaces described in any given time by a falling body, urged by any powers, reckoning from the beginning of its descent, are proportionable to those powers. Consequently the centripetal force of the moon revolving in its orbit, will be to the force of *gravity* on the surface of the earth, as the space which the moon would describe in falling, any little time, by her centripetal force towards the earth, if she had no circular motion at all, to the space a body near the earth would describe in falling, by its *gravity* towards the same.

Now, by a natural calculus of those two spaces, it appears, that the first of them is to the second, i. e. the centripetal force of the moon revolving in her orbit, is to the force of *gravity* on the surface of the earth, as the square of the earth's semidiameter to the square of the semidiameter of her orbit: which is the same ratio as that of the moon's centripetal force in her orbit, to the same force near the surface of the earth.

The moon's centripetal force, therefore, is equal to the force of *gravity*. These forces, consequently, are not different, but they are one and the same: for, were they different, bodies acted on by the two powers conjointly, would fall towards the earth, with a velocity double to that arising from the sole power of *gravity*.

It is evident, therefore, that the moon's centripetal force, whereby she is retained in her orbit, and prevented from running off in tangents, is the very power of *gravity* of the earth, extended thither.

This reasoning may be further illustrated and confirmed in the following manner: let R A E, *Tab. III. astronomy, fig.* 78, represent the earth, T its centre, V L the orbit of the moon, and L C a part of it described by the moon in a minute, which is equal to $\frac{1}{39343}$ of the whole periphery, or 33 seconds of a degree: because the moon completes her whole course in 27 days, 7 hours, 43 minutes, or in 39343 minutes. Moreover, the circumference of the earth, according to M. Picart's mensuration, is 123246600 Paris feet, and therefore its semidiameter TA = 19613800 feet; and T L, the semidiameter of the moon's orbit, will be 1176948000 feet, or = 60 times T A: and the versed line L D of the arc L C = 33″, computed by means of tables, or B C, will be 15,; feet, nearly; or, L D may be found without tables thus: the whole circumference of the moon's orbit, or 60 × 123246600, is equal to 7394976000, which, divided by 39343, will give the arc L C = 187961 feet: but by a well known theorem in geometry, supposing the arc LC, which is a very small part of the moon's orbit, to be rectilinear, $LC^2 = LD \times 2LT$, i. e. $LD = \frac{LC^2}{2LT}$, or the square of 187961, which is 35329337521, divided by 2353860000, will give 15,013, &c.

Note, a distance of the moon somewhat greater than 60 times the diameter of the earth would afford a more exact result: and the force whereby the moon is restrained in its orbit should also be increased in the proportion of 17572 to 17828, in order to have the exact centripetal force of the moon, such as it would be undiminished by the action of the sun, and with this correction the above number 15,013, &c. will become 15,097, &c. or

15$\frac{1}{10}$, very nearly. See Newton's Princip. lib. i. Prop. 43. cor. 2. and lib. iii. prop. 3. In either way of calculation it appears that the force, whereby the moon is drawn off from the tangent L B, or retained in its orbit, impels it towards the centre of the earth about 15$\frac{1}{12}$ Paris feet in one minute: but this force, being known from the elliptic figure of her orbit to be reciprocally proportional to the square of the diſtance, would impel the moon, ſuppoſed to be at the ſurface of the earth, through a ſpace equal to 60 × 60 × 15$\frac{1}{12}$ feet in one minute. But bodies, impelled by the force of *gravity*, fall near the ſurface of the earth through the ſpace of 15$\frac{1}{12}$ Paris feet in one ſecond, and the ſpaces being as the ſquares of the times, through 60 × 60 × 15$\frac{1}{12}$ in a minute. Wherefore as the force, by which the moon is retained in its orbit, and the force of *gravity* produce the ſame effects in the ſame circumſtances, and tend towards the ſame point, they are the ſame forces.

The moon, therefore, gravitates towards the earth; and the earth reciprocally towards the moon: which is further confirmed by the phenomena of the TIDES.

The like reaſoning might be applied to the other planets. For, as the revolutions of the primary planets round the ſun, and thoſe of the ſatellites of Jupiter and Saturn round their primaries are phenomena of the ſame kind as the revolution of the moon round the earth; as the centripetal powers of the primary are directed towards the centre of the ſun, and thoſe of the ſatellites towards the centres of their primaries; and, laſtly, as all theſe powers are reciprocally as the ſquares of the diſtances from the centres; it may ſafely be concluded, that the power and cauſe are the ſame in all.

Therefore, as the moon gravitates towards the earth, and the earth towards the moon; ſo do all the ſecondaries to their primary ones; the primaries to their ſecondary ones; ſo, alſo, do the primary ones to the ſun, and the ſun to the primary ones. Newton's Princip. lib. iii. prop. 4, 5, 6. Greg. Aſt. lib. i. ſect. 7. prop. 46 and 47.

GRAVITY, *phenomena, or properties of, univerſal.* 1. All the ſeveral particles of all bodies in nature *gravitate* to all the particles of all other bodies.

To what has been urged in proof hereof, from the analogy between the motions of the ſeveral bodies in our ſyſtem, it may be added, that Saturn is actually obſerved by aſtronomers to change its courſe when neareſt to Jupiter: and Jupiter, alſo, is found to diſturb the motion of the ſatellites of Saturn. So that the gravitation of thoſe bodies is matter of actual obſervation.

2. The quantity of this *gravity*, at equal diſtances, is always proportional to the quantity of matter in the gravitating bodies. For the powers of *gravity* are as the quantities of motion they generate; which quantities in unequal bodies, equally ſwift, are to each other as the quantities of matter. Conſequently, ſince unequal bodies, which are equally ſwift, are to each other as the quantities of matter; therefore, ſince unequal bodies at the ſame diſtance from the attracting body are found to move equally ſwift, by *gravity*, it is evident, the forces of *gravity* are proportional to the quantities of matter.

3. The proportion of the increaſe, or decreaſe, of *gravity* in the approach, or removal of bodies from each other, is this; that the force is reciprocally in a duplicate ratio, i. e. it is as the ſquares of the diſtance. Thus, ſuppoſe a body of an hundred pounds, at the diſtance of ten diameters from the earth; the ſame body, if its diſtance were but half ſo great, would have quadruple the weight: if its diſtance were but one-third of the former, its weight would be nine times as great, &c. Hence we deduce the following corollaries. 1. That at equal diſtances from the centres of homogeneal bodies, the *gravity* is directly as the quantity of matter, and inverſely as the ſquare of the diameter. 2. That in the ſurfaces of equal, ſpherical, and homogeneous bodies, the gravities are as the denſities. 3. That on the ſurfaces of ſpherical, homogeneous, equally denſe, but unequal bodies, the *gravities* are inverſely as the ſquares of the diameters. 4. That if both the denſities and diameters differ, the *gravities* on the ſurfaces will be in a ratio compounded of the denſities and the diameters. Laſtly, that a body placed any where, within a hollow ſphere, which is homogeneous, and every where of the ſame thickneſs, will have *gravity* whereſoever it be placed: the oppoſite *gravities* always preciſely deſtroying each other. For the particular laws of the deſcent of bodies, by the force of *gravity*, ſee DESCENT *of Bodies*, and CENTRIPETAL *Force*.

GRAVITY, *cauſe of.* We have various theories advanced by the philoſophers of various ages to account for this grand principle of gravitation. The ancients, who were only acquainted with particular *gravity*, or the tendency of ſublunar bodies towards the earth, aimed no farther than at a ſyſtem which might anſwer the more obvious phenomena of the ſame; but the moderns, as their principle is higher, and more extenſive, ſo ſhould their theory be.

However, we find ſome hints concerning the gravitation of celeſtial bodies in the account tranſmitted to us of the doctrines of Thales and his ſucceſſors; but Pythagoras ſeems to have been better acquainted with it, and is ſuppoſed to have had a view to it, in what he taught concerning the HARMONY *of the ſpheres.*

Ariſtotle, and the Peripatetics, content themſelves to refer *gravity* or weight to a native inclination in heavy bodies to be in their proper place or ſphere, the centre of the earth.

Copernicus aſcribes it to an innate principle in all parts of matter, whereby, when ſeparated from their wholes, they endeavour to return to them again the neareſt way.

In anſwer to Ariſtotle and his followers, who conſidered the centre of the earth as the centre of the univerſe, he obſerved, that it was reaſonable to think there was nothing peculiar to the earth in this principle of *gravity*; that the parts of the ſun, moon, and ſtars tended likewiſe to each other, and that their ſpherical figure was preſerved in their various motions by this power. Copern. Revol. lib. i. cap. 9.

But neither of theſe ſyſtems aſſigns any phyſical cauſe of this great effect: they only amount to this, that bodies deſcend, becauſe they are inclined to deſcend.

Kepler, in his preface to the commentaries concerning the planet Mars, ſpeaks of *gravity* as of a power that was mutual betwixt bodies, and tells us, that the earth and moon tend towards each other, and would meet in a point ſo many times nearer to the earth than to the moon, as the earth is greater than the moon, if their motions did not hinder it. He adds, that the TIDES ariſe from the *gravity* of the waters towards the moon. To him we alſo owe the important diſcovery of the analogy between the diſtances of the ſeveral planets from the ſun, and the periods in which they complete their revolutions: viz. that the ſquares of their periodic times are always in the ſame proportion as the cubes of their mean diſtances from the ſun. Nevertheleſs, Kepler, Gaſſendus, Gilbert, and others, aſcribe *gravity* to a certain magnetic attraction of the earth. Theſe authors conceive the earth to be one great magnet continually emitting effluvia, which lay hold on all bodies, and draw them toward the earth. But this, we have obſerved, is inconſiſtent with the ſeveral phenomena.

Deſcartes, and his followers, Rohault, &c. attribute *gravity* to an external impulſe, or truſion of ſome ſubtle matter. By the rotation of the earth, ſay they, all the parts and appendages thereof neceſſarily endeavour to recede from the centre of rotation: but they cannot, all, actually recede, as there is no vacuum or ſpace to receive them.

If now we ſuppoſe the earth ABCD, *Tab. Mechan. fig.* 8. and L a terreſtrial body placed in the pyramidal ſpace, AEB; it follows that the matter in this pyramid will have ſo much leſs endeavour to recede from the centre, as the body L has a leſs endeavour than the fluid matter whoſe place it poſſeſſes. Hence it will follow, that the matter of adjacent pyramids receding with more force; that in the pyramid AEB, and particularly the body L, will be thereby driven toward the centre for the ſame reaſons as cork, though a heavy body, aſcends in water. This hypotheſis, though ingenious enough, yet, as it is founded on the ſuppoſition of a plenum, is overthrown by what has been ſince proved of the exiſtence of a vacuum. See CARTESIAN *Philoſophy.*

Dr. Hook inclines to an opinion much like that of Deſcartes: *gravity* he thinks deducible from the action of a moſt ſubtle medium, which eaſily pervades and penetrates the moſt ſolid bodies; and which, by ſome motion it has, deſtrudes all earthly bodies from it, towards the centre of the earth.

Voſſius, and many others, give partly into the Carteſian notion, and ſuppoſe *gravity* to ariſe from the diurnal rotation of the earth round its axis.

Dr. Halley, deſpairing of any ſatisfactory theory, chooſes to have immediate recourſe to the agency of the Almighty. So Dr. Clarke, from a view of ſeveral properties of *gravity*, concludes, that it is no adventitious effect of any motion, or ſubtil matter, but an original and general law impreſſed by the Almighty on all matter, and preſerved therein by ſome efficient power penetrating the very ſolid and intimate ſubſtance thereof; as being found always proportionable, not to the ſurfaces of bodies or corpuſcles, but to their ſolid quantity and contents. It ſhould, therefore, be no more inquired, why bodies gravitate, than how they came to be firſt put in motion. Annot. in Rohault. Phyſ. part i. cap. xi. ſect. 16.

Dr.

Dr. s'Gravesande, in his Introduct. ad Philosoph. Newton. contends, that the cause of *gravity* is utterly unknown; and that we are to look on it no otherwise than as a law of nature, originally and immediately impressed by the Creator, without any dependence on any second law or cause at all. Of this he thinks the three following considerations sufficient proof.

1. That *gravity* requires the presence of the gravitating or attracting body: for the satellites of Jupiter, e. gr. gravitate towards Jupiter, wherever he be.

2. That the distance being supposed the same, the velocity wherewith bodies are moved, by the force of *gravity*, depends on the quantity of matter in the attracting body: and the velocity is not changed, let the mass of the gravitating body be where it will.

3. That if *gravity* do depend on any known law of motion, it must be some impulse from an extraneous body; whence, as *gravity* is continual, a continual stroke must also be required.

Now, if there be any such matter continually striking on bodies, it must be fluid, and subtile enough to penetrate the substance of all bodies: but how small a body subtile enough to penetrate the substance of the hardest bodies, and so rare as not insensibly to hinder the motion of bodies, be able to impel vast bodies towards each other with such force? how does this force increase in the ratio of the mass of the body, towards which the other body is moved? whence is it that all bodies, supposing the same distance, and the same body gravitated to, move with the same velocity? can a fluid, which only acts on the surface either of the bodies themselves, or their internal particles, communicate such a quantity of motion to bodies, which in all bodies shall exactly follow the proportion of the quantity of matter in them?

Mr. Cotes goes yet farther; giving a view of sir Isaac Newton's philosophy, he asserts that *gravity* is to be ranked among the primary qualities of all bodies; and deemed as essential to matter, as extension, mobility, or impenetrability. Præfat. ad Newton. Princip.

But this author may seem to have overshot the mark. His great master, sir Isaac Newton himself, disclaims the notion; and to shew that he does not take *gravity* to be essential to bodies, he gives us his opinion about the cause; choosing to propose it by way of query, as not being yet sufficiently satisfied about its experiments.

This query we shall subjoin at large. After having shewn, that there is a medium in nature vastly more subtile than air, by whose vibrations light communicates heat to bodies, and is itself put into alternate fits of easy reflection, and easy transmission, and sound propagated; and by the different densities whereof the refraction and reflection of light are performed;

He proceeds to inquire;

"Is not this medium much rarer within the dense bodies of the sun, stars, planets, and comets, than in the empty celestial spaces between them? and in passing from them to greater distances, doth it not grow denser and denser perpetually, and thereby cause the *gravity* of those great bodies towards one another, and of their parts towards the bodies; every body endeavouring to recede from the denser parts of the medium towards the rarer?

"For if this medium be supposed rarer within the sun's body, than at its surface, and rarer there than at the hundredth part of an inch from his body, and rarer there than at the fiftieth part of an inch from his body, and rarer there than at the orb of Saturn; I see no reason why the increase of density should stop any where, and not rather be continued through all distances from the sun to Saturn, and beyond.

"And though this increase of density may at great distances be exceeding slow; yet if the elastic force of this medium be exceeding great, it may suffice to impel bodies from the denser parts of the medium towards the rarer with all that power which we call *gravity*.

"And that the elastic force of this medium is exceeding great, may be gathered from the swiftness of its vibrations. Sounds move about 1140 English feet in a second of time, and in seven or eight minutes of time, they move about one hundred English miles: light moves from the sun to us in about seven or eight minutes of time, which distance is about 70000000 English miles, supposing the horizontal parallax of the sun to be about twelve seconds; and the vibrations, or pulses of this medium, that they may cause the alternate fits of easy transmission, and easy reflection, must be swifter than light, and by consequence above 700000 swifter than sounds; and therefore the elastic force of this medium, in proportion to its density, must be above 700000 × 700000 (that is, above 490000000000) times greater than the elastic force of the air is in proportion to its density: for the velocities of the pulses of elastic mediums are in a subduplicate ratio of the elasticities and the rarities of the mediums taken together.

"As magnetism is stronger in small loadstones than in great ones, in proportion to their bulk; and *gravity* is stronger on the surface of small planets, than those of great ones, in proportion to their bulk; and small bodies are agitated much more by electric attraction than great ones: so the smallness of the rays of light may contribute very much to the power of the agent by which they are refracted; and if any one should suppose, that æther (like our air) may contain particles which endeavour to recede from one another (for I do not know what this æther is), and that its particles are exceedingly smaller than those of air, or even than those of light; the exceeding smallness of such particles may contribute to the greatness of the force by which they recede from one another, and thereby make that medium exceedingly more rare and elastic than air, and of consequence, exceedingly less able to resist the motion of projectiles, and exceedingly more able to press upon gross bodies by endeavouring to expand itself." Optics, p. 325, &c.

GRAVITY, in *Mechanics*, denotes the conatus or tendency of bodies toward the centre of the earth.

That part of mechanics which considers the motion of bodies arising from *gravity*, is peculiarly called STATICS.

Gravity, in this view, is distinguished into *absolute*, and *relative*.

GRAVITY, *absolute*, is that wherewith a body descends freely through an unresisting medium.

The laws of absolute *gravity* see under DESCENT *of bodies*, ACCELERATION, MOTION, *Inclined* PLANE, &c.

GRAVITY, *relative*, is that wherewith a body descends after having spent part of its weight in overcoming some resistance.

Such is that wherewith a body descends along an inclined plane, where some part is employed in overcoming the resistance, or friction of the plane.

The laws of relative *gravity*, see under *inclined* PLANE, DESCENT, FLUID, RESISTANCE, &c.

GRAVITY, *centre of*. See CENTER *of gravity*.

GRAVITY, *diameter of*. See DIAMETER *of gravity*.

GRAVITY, *paracentric follicitation of*. See PARACENTRIC.

GRAVITY, *plane of*. See PLANE *of gravity*.

GRAVITY, *retardation from*. See RETARDATION.

GRAVITY, *in Hydrostatics*. The laws of bodies *gravitating* in fluids, make the business of HYDROSTATICS.

Gravity is here divided into *absolute* and *specific*.

GRAVITY, *absolute*, or *true*, is the whole force wherewith the body tends downward.

GRAVITY, *specific*, called also *relative*, *comparative*, and *apparent* GRAVITY, is the excess of *gravity* in any body, above that of an equal quantity or bulk of another; and denotes that *gravity*, or weight, peculiar to each species, or kind of natural body; and whereby it is distinguished from all other kinds.

In this sense, a body is said to be *specifically heavier* than another, when under the same bulk it contains a greater weight than that other; and that other is said to be *specifically lighter* than the first. Thus, if there be two equal spheres, each a foot in diameter; the one wood, the other lead, since the leaden one is found heavier than the wooden one, it is said to be *specifically*, or in *species*, *heavier*; and the wooden one *specifically lighter*.

This kind of *gravity*, some call *relative*; in opposition to *absolute gravity*, which increases in proportion to the quantity or mass of the body.

GRAVITY, *laws of, the specific, and levity of bodies*. I. If two bodies be equal in bulk, their *specific gravities* are, to each other, as their absolute *gravities*. Thus a body is said to be twice as heavy, *specifically*, as another, if it have twice its *gravity* under the same bulk.

Hence, the *specific gravities* of equal bodies are as their densities.

II. If two bodies, compared together, be of the same *specific gravities*, their absolute weights will be as their magnitudes or bulks.

III. The *specific gravities* of bodies of the same weight are in the reciprocal ratio of their bulks. Hence the masses of two bodies of the same weight are in a reciprocal ratio of their bulks.

IV. The *specific gravities* of two bodies are in a ratio compounded of the direct ratio of the absolute *gravities*, and the reciprocal one of their bulks. Hence, again, the *specific gravities* are as the densities.

V. The absolute *gravities* of two bodies will be in a compound ratio of their *specific gravities* and their bulks.

VI. The bulks of two bodies will be in a compound ratio of

of their abſolute *gravities* directly, and their *ſpecific gravities* inverſely.

VII. A body *ſpecifically* heavier than a fluid, loſes ſo much of its weight therein, as is equal to the weight of a quantity of the fluid of the ſame bulk.

For, ſuppoſe a cubic inch of lead immerged in water; a cubic inch of water will, thereby, be expelled from its place: but the weight of this water was ſuſtained by the reſiſtance of the ambient water. Therefore, ſuch a part of the weight of the leaden cube, muſt be ſuſtained by the reſiſtance of the ambient water, as is equal to the weight of the water expelled. The *gravity* of the body immerged, therefore, muſt be diminiſhed by ſo much.

Hence, 1. Since a fluid ſpecifically heavier, has a greater weight in the ſame bulk, than a lighter; the ſame body will loſe a greater part of its weight in a fluid, ſpecifically heavier, than in a lighter; and therefore is weighs more in a lighter than a heavier.

2. Equal homogeneous bodies weighing equally in air, loſe their equilibrium if one of them be immerged in a heavier fluid, the other in a lighter.

3. Since the ſpecific *gravities* are as the abſolute *gravities* under the ſame bulk; the ſpecific *gravity* of the fluid, will be to the *gravity* of the body immerged, as part of the weight loſt by the ſolid, to the whole weight.

4. Two ſolids equal in bulk, loſe the ſame weight in the ſame fluid: but the weight of the ſpecifically heavier body is greater than that of the ſpecifically lighter; therefore, the ſpecifically lighter loſes a greater part of its weight than the ſpecifically heavier.

5. Since the bulks of bodies equal in weight, are reciprocally as the ſpecific *gravities*; the ſpecifically lighter loſes more weight in the ſame fluid than the heavier; wherefore, if they be in equilibrio in one fluid, they will not be ſo in another; but the ſpecifically heavier, will preponderate, and that the more, as the fluid is denſer.

6. The ſpecific *gravities* of fluids, are as the weights loſt by the ſame ſolid immerged in the ſame.

VIII. *To find the ſpecific gravity of a fluid.* On one arm of a balance ſuſpend a leaden globe; and to the other, faſten a weight, which is an equilibrium therewith in the air. Immerge the globe ſucceſſively in the ſeveral fluids, whoſe ſpecific *gravities* are to be determined, and obſerve the weight which balances it in each. Theſe ſeveral weights, ſubtracted, ſeverally, from the firſt weight, the remainders are the parts of the weight loſt in each fluid. Whence the ratio of the ſpecific *gravity* of the fluids is ſeen.

Hence, as the denſities are as the ſpecific *gravities*; we find the ratio of the denſities of the fluids at the ſame time.

This problem is of the utmoſt uſe; as by it the degree of purity or goodneſs of fluids is eaſily found; a thing not only of ſervice in natural philoſophy, but alſo in common life, and in the practice of phyſic. See HYDROMETER.

That the ſpecific *gravity* may be found the more accurately; the weight of the thread not immerged in the fluid is to be ſubtracted from the weight of the ſolid in air; and the force neceſſary to make the thread ſubſide (if it be ſpecifically lighter) is to be added to the weight loſt. But if the thread that ſuſtains the ſolid be heavier than the fluid; the weight of the thread in the air is to be ſubtracted from the weight of the ſolid in air; and the weight the thread loſes from the weight loſt in the fluid. Indeed, this precaution may be ſpared, if in examining the ſpecific *gravity* of ſeveral fluids, care be taken that the ſame thread be immerged to the ſame depth in each.

IX. To determine the ratio which the ſpecific *gravity* of a fluid has to the ſpecific *gravity* of a ſolid that is ſpecifically heavier than the fluid.

Weigh any maſs of the ſolid in a fluid, and note the juſt weight therein: the ſpecific *gravity* of the fluid will be to that of the ſolid, as the part of the weight loſt by the ſolid to its whole weight.

X. The ſpecific *gravities* of equally heavy bodies, are reciprocally as the quantities of weight loſt in the ſame fluid. Hence we find the ratio of the ſpecific *gravities* of ſolids, by weighing maſſes thereof, that are equal in air, in the ſame fluid; and noting the weights loſt by each.

The ſpecific *gravities* of various ſolids, have been determined by many authors. Marin Ghetaldus particularly, tried the ſpecific *gravities* various bodies had, eſpecially metallic ones; which were borrowed thence by Oughtred. In the Philoſophical Tranſactions, we have ample tables of ſpecific *gravities*, by various authors. See Vol. xlv. p. 436, &c.

It will be ſufficient for us to give thoſe of ſome of the more uſual bodies, as determined with great care and accuracy by M. Petit; and publiſhed by F. Merſenne; and from him by ſeveral others.

TABLE of the ſpecific *gravities* of ſeveral ſolids.

An hundred pound weight in gold is equal in bulk to

7½ of mercury	38½ of fine tin
60 of lead	26 of loadſtone
54½ of ſilver	21 of marble
47½ of copper	14 of ſtone
45 of braſs	12½ of ſulphur
42 of iron	5 of wax
39 of tin	5½ of water

A TABLE of the ſpecific *Gravities* of ſolid and fluid Bodies.

A cubic inch of	Troy weight.			Avoirdupois weight.		Comparative weight.
	oz.	p.w.	gr.	oz.	drams.	
Very fine gold	10	7	3,83	11	5,80	19,637
Standard gold	9	19	0,44	10	14,90	18,888
Guinea gold	9	7	17,18	10	4,70	17,793
Moidore gold	9	0	10,84	9	14,71	17,140
Pure quickſilver	7	7	11,01	8	1,45	14,019
Lead	5	19	17,15	6	9,08	11,325
Fine ſilver	5	16	23,23	6	6,60	11,087
Standard ſilver	5	11	3,38	6	1,54	10,535
Copper	4	13	7,64	5	1,89	8,843
Plate braſs	4	4	9,60	4	10,09	8,000
Steel	4	2	20,12	4	8,70	7,832
Iron	4	0	15,20	4	6,77	7,645
Block tin	3	17	5,68	4	3,79	7,321
Spelter	3	14	12,88	4	1,42	7,065
Lead ore	3	11	17,76	3	14,96	6,800
Glaſs of antimony	2	15	10,89	3	0,89	5,280
German antimony	2	2	4,80	2	5,04	4,000
Copper ore	2	1	11,83	2	4,43	3,775
Diamond	1	15	20,88	1	15,48	3,400
Clear glaſs	1	13	5,58	1	13,16	3,150
Lapis lazuli	1	12	5,27	1	12,27	3,054
Welſh aſbeſtos	1	10	17,57	1	10,97	2,913
White marble	1	8	13,41	1	9,06	2,707
Black marble	1	8	12,03	1	9,02	2,704
Rock cryſtal	1	8	1,00	1	8,61	2,658
Green glaſs	1	7	15,58	1	8,26	2,620
Cornelian ſtone	1	7	1,21	1	7,73	2,568
Flint	1	6	19,03	1	7,53	2,542
Hard paving ſtone	1	5	22,87	1	6,77	2,460
Live ſulphur	1	1	2,40	1	2,52	2,000
Nitre	1	0	1,08	1	1,59	1,900
Alabaſter	0	19	18,74	1	1,35	1,875
Dry ivory	0	19	6,00	1	0,89	1,825
Brimſtone	0	18	23,76	1	0,66	1,800
Alum	0	17	21,91	0	15,72	1,714
Ebony	0	11	18,82	0	10,34	1,117
Human blood	0	11	2,89	0	9,76	1,054
Amber	0	10	20,79	0	9,54	1,030
Cow's milk	0	10	20,79	0	9,54	1,030
Sea water	0	10	20,79	0	9,54	1,030
Pump water	0	10	13,30	0	9,26	1,000
Spring water	0	10	12,94	0	9,25	0,999
Diſtilled water	0	10	11,42	0	9,20	0,993
Red wine	0	10	11,42	0	9,20	0,993
Oil of amber	0	10	7,63	0	9,06	0,978
Proof ſpirits	0	9	19,73	0	8,62	0,931
Dry oak	0	9	18,00	0	8,56	0,925
Olive oil	0	9	15,17	0	8,45	0,913
Pure ſpirits	0	9	3,27	0	8,02	0,866
Spirits of turpentine	0	9	3,76	0	7,99	0,864
Oil of turpentine	0	8	8,73	0	7,33	0,772
Dry crab-tree	0	8	1,09	0	7,08	0,765
Æther	0	7	14,00	0	6,65	0,720
Saſſafras wood	0	5	2,04	0	4,46	0,482
Cork	0	2	12,77	0	2,21	0,240

If you take away the decimal point from the numbers in the right hand column, or, which is the ſame, multiply them by 1000, they will ſhew how many avoirdupoiſe ounces are contained in a cubic foot of each body. If the magnitude of any body be multiplied by the ſpecific *gravity* in the table, the product will be the abſolute weight, e. gr. let it be required what weight of lead $\frac{1}{100}$ of a foot thick will cover a building whoſe area is 3000 feet. Anſ. $3000 \times \frac{1}{100}$ or$(300) \times 11315 = 3397500$ ounces, or about 94½ tons, the weight required. Again, the ſpecific *gravity* of any body, whoſe weight and bulk are known, may be found by dividing the weight by its magnitude: e. gr. let a piece of marble contain four cubic

bic feet, and weigh six hundred and three pounds, or 10800 ounces, then $\frac{10800}{4} = 2700$, its specific *gravity* as in the table, nearly. Farther, the magnitude of a body, whose weight is known, may be found by dividing the weight by the specific *gravity* in the table. See Hydrostatical *problem*.

To determine the specific *gravity* of bodies accurately, requires so much care, and is liable to so many difficulties, that we need not be surprised when we find authors differing from one another. Dr. Richard Davies, in the Philos. Transact. N° 488. has with great pains and judgment collected all the experiments of this kind, that have been made by the most accurate authors, shewing how widely they disagree, and pointing out the causes of their difference: and he has also given us the specific *gravities* of several substances from his own observations; to which we refer the curious. See also tables of the specific *gravities* of a great variety of metals, minerals, ores, stones, fossils, &c. animal, vegetable, and miscellaneous substances, and fluids, in Martin's Philosoph. Britan. vol. i. p. 290, &c. and Muschenbroeck. Introd. ad Phil. Nat. tom. ii. p. 536, &c. edit. 1762.

At different seasons of the year, the specific *gravities* of the same fluids, are found different. This was first discovered by M. Homberg: and Jean. Casp. Eisenschmidius, in his Disquisitio nova de Ponderibus, &c. gives us variety of experiments relating hereto: the principal whereof, to save the trouble of too frequent experiments, we shall here subjoin.

TABLE for the specific *Gravities* of several Fluids.

A cubic inch Paris measure.	In summer. oz. dr. gr.	In winter. oz. dr. gr.
Of mercury	7 1 66	7 2 14
Oil of vitriol	7 59	7 71
Spirit of vitriol	5 33	5 38
Spirit of nitre	6 24	6 44
Spirit of salt	5 49	5 55
Aquafortis	6 23	6 35
Vinegar	5 15	5 21
Distilled vinegar	5 11	5 15
Burgundy wine	4 67	4 75
Spirit of wine	4 32	4 42
Pale ale	5 1	5 9
Brown ale	5 2	5 7
Cow's milk	5 20	5 25
Goat's milk	5 24	5 28
Urine	5 14	5 19
Spirit of urine	5 45	5 53
Oil of tartar	7 27	7 43
Oil of olives	4 53	Is froze in winter
Oil of turpentine	4 39	4 46
Sea water	6 12	6 18
River water	5 10	5 13
Spring water	5 11	5 14
Distilled water	5 8	5 11

XI. A body specifically heavier, descends in a fluid specifically lighter, with a force equal to the excess of its weight, above that of an equal quantity of the fluid.

Hence, 1. The force which sustains a specifically heavier body in a fluid, is equal to the excess of the absolute *gravity* of the body, above that of the fluid, under the same bulk: e. gr. 47½ pound of copper loses 5½ pounds of its weight in water; therefore a power of 42 pounds is able to sustain it.

2. Since the excess of the weight of a solid over the weight of a fluid specifically heavier, is less than that over the weight of a specifically lighter fluid under the same bulk; it will descend with less force in a specifically heavier fluid than in a lighter; and, consequently, it will descend more slowly in the former than in the latter.

XII. A specifically lighter body, sinks in a heavier fluid, till the weight of a quantity of the fluid, equal in bulk to the part immersed, be equal to the weight of the whole body.

Hence, 1. Since the specific *gravities* of bodies of the same weight, are reciprocally as their bulks; and the bulks of fluids equal in weight, are as the parts of the same solid immerged therein; the specific *gravities* of fluids are reciprocally as the parts of the same body immerged therein.

2. A solid, therefore, immerges deeper in a lighter fluid than in a heavier, and deeper, as the proportion of the specific *gravity* of the solid to that of the fluid is greater.

3. If a body be of the same specific *gravity* with a fluid; the whole body will be immerged; and it will remain in any given place of the fluid.

4. If a specifically lighter body be wholly immerged in a fluid; it will be urged by the collateral columns of the fluid, to ascend with a force equal to the excess of the weight of the fluid, bulk for bulk, over the weight of the solid.

5. A body, therefore, specifically lighter, lying on the bottom of a vessel, will not be raised up, unless the heavier fluid rise above such a part, as is equal in bulk to a quantity of the fluid of the same weight with the whole solid.

XIII. The specific *gravity* of a solid is to the specific *gravity* of a lighter fluid, wherein it is immerged, as the bulk of the part immerged, is to the whole bulk.

XIV. The specific *gravities* of equal solids, are as their parts immerged in the same fluid.

XV. The weight and bulk of a specifically lighter body, and the weight of the specifically heavier fluid, being given, to find the force required, to keep the solid wholly immerged under the fluid.

As this force is equal to the excess of the weight of the fluid beyond that of an equal bulk of the solid; from the given bulk of the solid, and the weight of a cubic foot of water, find, by the rule of three, the weight of a bulk of water equal to that of the body. From this subtract the weight of the solid; the remainder is the force required. E. gr. suppose the force necessary to detain a solid eight feet in bulk, and 100 pounds in weight, under water, required: since a cubic foot of water is found to weigh 70 pound, the weight of water under the bulk of eight feet, is 560; whence, 140 pound, the weight of the solid, being subtracted; the remainder 460 pound, is the force necessary to detain the solid under water.

Hence, since a specifically lighter body ascends in a heavier fluid, with the same force that would prevent its ascent: by the present problem, we can likewise find the force wherewith a specifically lighter body ascends in a heavier.

XVI. The weight of a vessel, to be made of a specifically heavier matter; and that of a specifically lighter fluid, being given: to determine the cavity the vessel must have, to swim on the fluid.

The weight of a cubic foot of the fluid being given; the bulk of the fluid equal to the weight of the vessel, is found by the rule of three. If, then, the cavity be made a little bigger than this, the vessel will have less weight under the same bulk, than the fluid, and will therefore be specifically lighter than the same, and consequently, it will swim.

XVII. The force employed to retain a specifically lighter solid, under a heavier fluid; and the weight lost by a heavier solid in a lighter fluid, are each added to the weight of the fluid, and weigh together with it.

The several theorems here delivered, are not only all demonstrable from the principles of mechanics; but are conformable to experiment. In effect, experience is here found to answer exactly to calculation, as is abundantly evident from the courses of philosophical experiments, now frequently exhibited; where the laws of specific *gravitation* are well illustrated. See Hydrostatical *balance*.

Gravity *of the air*. See Weight *of the air*, Air, and Atmosphere.

Specific Gravity of *living men*. See Specific *Gravity*.

Gravity, in *Music*, is an affection of sound, whereby it becomes denominated *grave*, *low*, or *flat*.

Gravity stands in opposition to *acuteness*, which is that affection of sound, whereby it is denominated *acute*, *sharp*, or *high*.

The relation of *gravity* and acuteness is the principal thing concerned in music; the distinctness, and determinateness of which relation give sound the denomination of *harmonical*, or *musical*.

The degrees of *gravity*, &c. depend on the nature of the sonorous body itself, and the particular figure and quantity thereof: though, in some cases, they likewise depend on the part of the body where it is struck. Thus, e. gr. the sounds of two bells of different metals, and the same shape and dimensions, being struck in the same place, will differ as to acuteness and *gravity*; and two bells of the same metal will differ in acuteness, if they differ in shape or magnitude, or be struck in different parts.

So in chords, all other things being equal, if they differ either in matter, or dimensions, or tension, they will also differ in *gravity*.

Thus again, the sound of a piece of gold is much graver than that of a piece of silver of the same shape and dimensions; and in this case, the tones are, *ceteris paribus*, proportional to the specific *gravities*: so a solid sphere of brass, two feet in diameter, will sound graver than another of one foot diameter; and here the tones are proportional to the quantities of matter, or the absolute *weights*.

But

But it muſt be obſerved, that acuteneſs and *gravity*, as alſo loudneſs and lowneſs, are but relative things. We commonly call a ſound *acute* and loud, in reſpect to another which is *grave*, or low with reſpect to the former; ſo that the ſame ſound may be both *grave* and *acute*, and alſo loud and low, in different comparisons.

The degrees of acuteneſs and *gravity*, make the different tones, or tunes, of voice, or ſound; ſo we ſay one ſound is in tune with another, when they are in the ſame degree of *gravity*.

The immediate cauſe or means of this diverſity of tones lies very deep. The modern muſicians fix it on the different velocity of the vibrations of the ſonorous body: in which ſenſe *gravity* may be defined, a relative property of ſound, which, with reſpect to ſome other, is the effect of a leſſer number of vibrations accompliſhed in the ſame time, or of vibrations of a longer duration. In which ſenſe alſo, acuteneſs is the effect of a greater number of vibrations, or vibrations of a ſhorter duration.

If the vibrations be iſochronous, the ſound is called muſical, and is ſaid to continue at the ſame pitch. See CHORD and STRING, in *Muſic*.

If two or more ſounds be compared in the relation of *gravity*, &c, they are either *equal* or *unequal*, in the degree of tune. Such as are *equal*, or produced by iſochronous vibrations, are called UNISONS.

The *unequal*, including, as it were, a diſtance between each other, conſtitute what we call an interval in muſic; which is properly the difference, in point of *gravity*, between two ſounds.

Upon this inequality, or difference, does the whole effect depend; and in reſpect hereof it is, that theſe intervals are divided into CONCORDS and DISCORDS.

GRAUPEN, a term uſed by the German miners to expreſs the reſiduum of any ore after the regulus, or metalline part, it run from it. Thus the ores of biſmuth leave behind them, after the regulus is melted off, an earthy ſubſtance called *biſmuth graupen*, with which, mixt with ſlints and an alkali, they make a kind of ſmalt, not diſtinguiſhable from the true ſmalt made from cobalt. Phil. Tranſ. N° 390.

GRAVY, in *Cookery*, &c. *the juices of fleſh*, or fiſh, obtained from them by coction, elixation, friction, or the like.

GRAY, or GREY, a mixed colour, partaking of the two extremes, black and white. See DYING.

In the *Miners* they make ſeveral ſorts of *grays*: as the *branded* or *blackened gray*, which has ſpots quite black, diſperſed here and there. The *dappled gray*, which has ſpots of a darker colour than the reſt of the body. The *light* or *ſilver gray*, wherein there is but a ſmall mixture of black hairs. The *ſad* or *iron gray*, which has but a ſmall mixture of white. And the *brownish* or *ſandy-coloured gray*, where there are bay-coloured hairs mixed with the black.

GRAY, in *Zoology*, a name given in ſome counties of England to the BADGER.

GRAY is alſo uſed in ſome places for a ſpecies of wild-duck, more commonly known by the name of the *godwall*. See DUCK.

GRAYLING, or UMBER, the Engliſh name for the fiſh called by authors *thymallus*, and *thymus*, and by Artedi made a ſpecies of COREGONUS, and the SALMO *thymallus* of Linnæus.

It is of a long and flatted body, the belly is ſomewhat broad, and the back rigid and thin. It ſeldom exceeds a pound, or at the utmoſt a pound and half weight. The *irides* are ſilvery, tinged with yellow: the teeth very minute, ſeated in the jaws and roof of the mouth, but none on the tongue; the head is duſky; the covers of the gills of a gloſſy green; the back and ſides of a fine ſilvery grey, varied ſlightly, when the fiſh is juſt taken, with blue and gold; the ſide line is ſtraight; the ſcales are large, and the lower edges duſky, forming ſtrait rows from head to tail; the firſt dorſal fin has twenty one-rays; the three or four firſt are the ſhorteſt, the others almoſt of equal lengths; this fin is ſpotted, but all the others are plain; the tail is much forked.

It is caught in the freſh rivers and clear rapid ſtreams, chiefly in the mountainous counties of England, and in the like ſituations in Germany, and other kingdoms, and is one of the fineſt taſted of all the freſh water fiſh. It is common in Lapland, where the guts of it are uſed inſtead of rennet to make the cheeſe, which they get from the milk of the rein-deer. It is a voracious fiſh, riſes freely to the fly, and will very eagerly take a bait. It feeds on worms, and ſpawns in May. See *Tab. of Fiſhes*, N° 7. Willughby and Pennant.

GRAYMILL, in *Botany*. See GROMWELL.

GREASE, among *Farriers*, &c. a ſwelling and gourdineſs of the legs of a horſe, very frequently happening after a journey.

If the *groſe* be an attendant of ſome other diſeaſe, it will be in vain to attempt the cure before the diſeaſe be removed that is the original cauſe of it; and therefore, if it be a hectic, the *yellows*, or the farcin, &c. the directions given for thoſe diſeaſes are to be followed, and in the mean time proper applications are to be uſed outwardly for the *groſe*.

If the *groſe* proceed from the common and ordinary accidents, and the horſe has no other diſtemper upon him, then applications that are peculiar to this diſtemper are to be followed. In general, keeping the heels clean, by waſhing them with ſoap-ſuds, chamber-lye, or vinegar and water, moderate exerciſe, a large and convenient ſtall, with good dreſſing, are the beſt remedies. When the heels are cracked, and diſcharge a noiſeous matter, or are full of hard lumps, after cutting off the hair, poultices, made of boiled turnips and lard, with a handful of powdered linſeed, or oatmeal and rye-flour, with a little common turpentine and hog's lard, boiled up with ſtrong beer grounds, or red wine lees, ſhould be applied to them, for two or three days, over the digeſtive ointment: theſe will promote a diſcharge, which may be dried up with the following waſh: take white vitriol and burnt alum, of each two ounces; Ægyptiacum, one ounce; lime-water, a quart or three pints: waſh the ſores with a ſponge dipped in this mixture three times a day, and apply the common white ointment, ſpread on tow; to which may be added ſugar of lead, in the proportion of two drams to an ounce of ointment. If the diſorder has advanced to a greater height, and the horſe has been well fed and pampered, it may be neceſſary to have recourſe, not only to bleeding, rowels, and repeated purging, but to the uſe of diuretic medicines. For this purpoſe the nitre balls may be given in the quantity of two ounces a day, for a month or ſix weeks; they may be either mixed with honey, or given in the horſe's *feeds*; one dram of camphor may be added to the nitre. The legs ſhould be alſo fomented twice a day with diſcutient fomentations, in which a handful or two of wood-aſhes has been boiled: the above poultice applied, the ſores dreſſed with the green ointment, and when they are properly digeſted, dried up with the wash already recommended. If the ſores are very foul, they ſhould be dreſſed with two parts of the wound ointment, and one of Ægyptiacum, over which the following preparation, ſpread on thick cloths, ſhould be rolled on: take of black ſoap one pound, honey half a pound, burnt alum four ounces, powdered verdegriſe two ounces, and a ſufficient quantity of wheat flour. If the diuretic balls ſhould not ſucceed with this treatment, they muſt be changed for the antimonial and mercurial alteratives. Bartlet's Farriery.

GREASE *mitten*, is a diſtemper incident to horſes, in which the fat is melted by violent exerciſe in hot weather, and diſcharged with their dung. This diſeaſe is always attended with a fever, heat, reſtleſſneſs, ſtarting and trembling, inward ſickneſs, ſhortneſs of breath, and ſometimes with the ſymptoms of a pleuriſy. For the cure, bleed plentifully, and repeat it for two or three days ſucceſſively in ſmaller quantities; put in two or three rowels and adminiſter cooling emollient glyſters. Let the horſe drink plenty of warm water or gruel, with cream of tartar or nitre. When he has recovered his appetite, and the fever is removed, gentle aloetic purgings, conſiſting of half an ounce or ſix drams of fine aloes, ſhould be given once a week for a month or ſix weeks. The purge may be prepared thus: take of Succotine aloes ſix drams; of gum guaiacum, half an ounce; of diaphoretic antimony and powder of myrrh, of each two drams; and make them into a ball with ſyrup of buckthorn: or it may be prepared with an ounce of aloes, ſix drams of diapente, and a ſpoonful of oil of amber. The diuretic nitre medicine recommended in the article GREASE will be found of great uſe. Bartlet's Farriery.

GREASE, among *Hunters*, denotes the fat of a boar or hare.

GREAT, a term of COMPARISON, denoting a thing to have more extenſion than ſome other to which it is referred.

Thus we ſay, a *great* ſpace; a *great* diſtance; a *great* figure; a *great* body, &c.

GREAT is likewiſe uſed figuratively, in matters of morality, &c. to ſignify ample, noble, elevated, extraordinary, important, &c.

Thus we ſay, Shakſpeare was a *great* genius; queen Elizabeth had a *great* ſoul; Cromwell was a man of *great* deſigns; Da Vinci, a *great* painter; Galileo a *great* philoſopher; Boſſu a *great* critic, &c.

GREAT is alſo a title or quality appropriated to certain princes, and other illuſtrious perſonages.

Thus we ſay the *great* Turk; the *great* Mogul; the *great* cham of Tartary; the *great* duke of Florence, &c.

GREAT is alſo a ſurname beſtowed on ſeveral kings and emperors.

Thus we ſay, Alexander the *great*; Cyrus the *great*; Charles the *great*, or Charlemagne; Henry the *great* of France, &c. So the Engliſh frequently ſay Edward the *great*, or the *great* Edward: William the *great*, meaning king William III. or the *great* William. The French ſay, Louis the *great*, *le grand*, ſpeaking of the late Louis XIV. Giles of Paris ſays, Charlemagne firſt got the ſurname *great* from the tallneſs and eminence of his ſtature. Helgaud adds, that Hugh the *great* of France was thus denominated on account of his great piety, goodneſs, &c.

GREAT is alſo applied to ſeveral officers, who have pre-eminence over others.

Thus we ſay, the lord *great* chamberlain; the *great* marſhal of Poland, &c.

GREAT *circles of the ſphere*. See *Great* CIRCLE.

GREAT *circle ſailing*. See SAILING.

GREAT *apparatus*. See APPARATUS.

GREAT *artery*. See ARTERY.

GREAT *bairam*. See BAIRAM.

GREAT *bear*. See URSA *major*.

GREAT *gun*. See CANNON and GUN.

GREAT *letters*. See CAPITALS.

GREAT *maſs*. See MASS.

GREAT *officers*. See OFFICER.

GREAT *repeat*. See REPEAT.

GREAT *ſeal*. See SEAL.

GREAT *tithes*. See TITHES.

GREAT *wardrobe*. See WARDROBE.

GREAT *wheel*, in *Clock* or *Watch-work*, is that wheel which the weight, ſpring, or fuſee, firſt moves.

GREAT *work*, in *Chemiſtry*, is the alchemical proceſs whereby gold is made, or pretended to be made.

GREAT *year*. See PLATONIC *year*.

GREATER *barons*. See BARON.

GREATER *equatorial diſtance*. See DISTANCE.

GREATER *excommunication*. See EXCOMMUNICATION.

GREATER *faſts*. See FASTI.

GREATER *hexachord*. See HEXACHORD.

GREBE, in *Ornithology*, is claſſed by Linnæus under the genus of COLYMBUS. See DIVER.

The diſtinguiſhing characters of this ſpecies of birds are, that the bill is ſtrong, ſtraight, and ſharp-pointed; that they have no tail, and that the legs are flat, thin, and ſerrated behind with a double row of notches. The *great creſted grebe*, or *colymbus criſtatus* of Linnæus, has between the bill and eyes a ſtripe of black naked ſkin, and on the head a large duſky creſt ſeparated in the middle; the cheeks and throat are ſurrounded with a long pendant ruff of a bright tawny colour, edged with black; the chin is white; from the bill to the eye is a black line, and above that a white one: the hind part of the neck and back are of a ſooty hue; the rump is covered with long ſoft down; the breaſt and belly are of a moſt beautiful ſilvery white, gloſſy as ſatin, and applied to the ſame uſes with thoſe of the *tippet grebe*. They breed in the meres of Shropſhire and Cheſhire, and in the eaſt fen in Lincolnſhire, where they are called *gaunts*. The bird ſits and hatches its eggs in a neſt floating on the water, among the reeds and flags. It preys on fiſh, and is almoſt perpetually diving, and is never ſeen on land; the fleſh is rank, but the fat is recommended in rheumatic pains, cramps, and paralytic contractions. Pennant. *Tab.* II. *Birds*, N° 15.

The *little* or *eared grebe*, or *colymbus auritus* of Linnæus, is the *didapper*, or *dob-chick* of other writers.

The *tippet grebe*, or *colymbus urinator* of Linnæus, called alſo *colymbus major*, *greater loon*, and *greater dob-chick* by other writers, differs from the great creſted *grebe* in being rather leſs, and wanting the creſt and ruff. This ſpecies is ſcarce in England, but is common in the winter-time on the lake of Geneva, where they appear in flocks of ten or twelve. They are killed for the ſake of their ſkins, the underſide of which being dreſt with the feathers on, are made into muffs and tippets. Pennant. *Tab.* II. *Birds*, N° 16.

GREE, in our *Law Books*, ſignifies agreement, contentment, or good liking. Thus, to make *gree* to the parties, is to ſatisfy them for offence done. "Judgment ſhall be put "in ſuſpence, till *gree* be made to the king of his debt." Stat. 25 Edward III.

The word is formed from the French *gré*, *good will*, *good liking*, or *allowance*.

GREEK *language*, or *ancient* GREEK, is the language ſpoken by the ancient Grecians, and ſtill preſerved in the works of their authors, as Plato, Ariſtotle, Iſocrates, Demoſthenes, Thucydides, Xenophon, Homer, Heſiod, Sophocles, Euripides, &c.

The *Greek* has been preſerved entire longer than any other language known, notwithſtanding all the revolutions that have happened in the country where it was ſpoken. See ENGLISH.

Yet, from time to time of the removal of the ſeat of empire to Conſtantinople, in the fourth century, it has been gradually altering: the alterations at firſt did not affect the analogy of the tongue, the conſtruction, inflexions, &c. There were only new words, new riches acquired by taking in the names of new dignities and offices, and the terms of art it was before unacquainted with; but, at length, the incurſions of the Barbarians, and eſpecially the invaſion of the Turks, wrought much more conſiderable alterations.

The *Greek* has a great copia or ſtock of words: its inflexions are as remarkable for their variety, as thoſe of moſt of the other European tongues for their ſimplicity.

It has three numbers, ſingular, dual, and plural, and abundance of tenſes in its verbs, which makes a variety in diſcourſe, prevents a certain dryneſs which always accompanies a too great uniformity, and renders the language peculiarly fit for all kinds of verſe.

The uſe of the participles of the aoriſtus and preterit, together with the compounded words, wherein it abounds, give it a peculiar force and brevity, without taking any thing from its perſpicuity.

The proper names in the *Greek* language are ſignificative, as in the oriental as well as moſt of the modern languages, where the learned ſtill find ſome, though remote, character of their origin.

The *Greek* was the language of a polite people, who had a great taſte for arts and ſciences, which they cultivated with ſucceſs. In the living tongues aroſe ſtill preſerved a vaſt number of *Greek* terms of art; ſome deſcended to us from the Grecians, and others formed anew. When a new invention, machine, right, order, inſtrument, &c. has been diſcovered, recourſe has been commonly had to the *Greek* for a name; the facility wherewith words are there compounded, readily affording us names expreſſive of the uſes, effect, &c. of ſuch inſtruments. Hence *aræometer*, *thermometer*, *barometer*, *micrometer*, *logarithm*, *teleſcope*, *microſcope*, *hexedron*, &c.

GREEK, *modern* or *vulgar*, is the language now ſpoken in Greece, and called Ρωμαικα γλωσσα, from Conſtantinople being called *Roma Nova*.

There have been few books written in this language, from the taking of Conſtantinople by the Turks; ſcarce any thing but ſome catechiſms, and the like pieces, compoſed or tranſlated into the vulgar *Greek*, by the Latin miſſionaries.

The native *Greeks* are contented to ſpeak the language without cultivating it; the Turkiſh politics not allowing any of the ſubjects of their eſtates to apply themſelves to the arts and ſciences.

It is not eaſy to aſſign the preciſe difference between the *vulgar* and the *ancient Greek*: it conſiſts of the terminations of nouns, pronouns, verbs, and other parts of ſpeech, which make a difference between thoſe two languages much like that obſerved between ſome of the dialects of the Italian or Spaniſh: we inſtance in thoſe languages, as being the moſt known; but we might have ſaid the ſame thing of the Hebrew, Sclavonic, &c. dialects.

The *modern Greek* alſo curtails words, runs them into one another, and adds a ſort of enclitic particles to the end of them: it confounds the vowels υ, ι, ε, and the diphthongs αι and ει, which they pronounce and often write only ιτα. They likewiſe often confound caſes, moods, tenſes, and particles. See Beregood's Inquiry concerning the Diverſity of Languages, &c. chap. 2.

Beſides, the modern *Greek* has divers new words not in the ancient; particularly ſeveral participles which appear as expletives, and which are introduced to characterize certain tenſes of verbs, and other expreſſions, which would have had the ſame meaning without ſuch particles, had cuſtom diſpenſed with them; divers names of dignities and offices, unknown to the ancient *Greeks*; and abundance of words borrowed from the vulgar tongues of the neighbouring nations.

Accordingly one may diſtinguiſh three ages of the *Greek* tongue: the firſt ends at the time when Conſtantinople became the capital of the Roman empire; not but there were ſeveral books, eſpecially of the fathers of the church, written with great purity after that time; but as religion, law, and policy, both civil and military, began then to introduce new words into the language, it ſeems neceſſary to begin the ſecond age of the *Greek* tongue from that epocha; which laſted to the taking of Conſtantinople by the Turks, where the laſt age commences.

GREEK *Bible*. See BIBLE.

The New Teſtament was tranſlated into modern *Greek* by Maximus a monk, who flouriſhed about the year 1630. It was undertaken at the requeſt of Cornelius Haga, the Dutch ambaſſador at the Port of Conſtantinople, and is prefaced and recommended by the patriarch Cyrillus Lucaris. An edition of this verſion, with the ancient *Greek*

in one column, and the modern *Greek* in another, was published at Geneva in 1638. There was another edition printed at London in duodecimo in the year 1703. The tranſlation appears to be very literal, and ſo cloſe as to be ſometimes obſcure.

GREEK *church* is that part of the Chriſtian church which is eſtabliſhed in Greece; extending likewiſe to ſome other parts of Turky.

It is thus called in Europe, Aſia, and Africa, in contradiſtinction from the *Latin* or *Romiſh* church; as alſo the *Eaſtern* church, in diſtinction from the *Weſtern*.

The Romaniſts call the *Greek* church the *Greek ſchiſm*, becauſe the Greeks do not allow the authority of the pope, but depend wholly, as to matters of religion, on their own patriarchs. They have treated them as ſchiſmatics ever ſince the revolt, as they call it, of the patriarch Photius. See CHURCH.

GREEK *year*. See YEAR.

GREEN, one of the original colours of the rays of light. Graſs and herbs, and even all vegetables in places expoſed to the open air, are *green*; and thoſe in ſubterraneous places, or places inacceſſible to the air, white and yellow. Thus when wheat, or the like, germinates under-ground, it is white or yellow; and when it ſees the open air *green*; though this too is yellow before it be *green*.

GREENS, *artificial*, are very rarely ſimple colours, but produced by mixture of yellow and blue.

Two powders, the one blue, and the other yellow, well mixed, appear perfectly *green*; though, when viewed with a microſcope, we obſerve a chequer of blue and yellow.

The tincture of red roſes with oil of tartar per deliquium, or with ſpirit of ſal ammoniac, produces *green*. The tincture of many red flowers is changed into *green* by an alkali. The tincture of red roſes, and the yellow tincture of crocus, or the blue tincture of cyanus, and the white ſpirit of ſal ammoniac, produce *green*. The ſolution of verdigriſe becomes colourleſs by the affuſion of the ſpirit of nitre, and by the affuſion of the oil of tartar it becomes *green* again.

The dyers make divers ſhades, or caſts of *green*, as *light green*, *yellow green*, *graſs green*, *laurel green*, *ſea green*, *dark green*, *parrot green*, and *celadon green*.

All the *greens* are firſt dyed blue, then taken down with woad, verdigriſe, &c. and then *greened* with the weed, there being no one ingredient that will give *green* alone. See DYEING.

GREEN, *mountain*, or *Hungary* GREEN, is a ſort of *greeniſh* powder found in little grains, like ſand, among the mountains of Kernauſent in Hungary, and thoſe of Moldavia. Though ſome hold, that this mountain *green* is factitious, and the ſame with that the ancients called *flos æris*, prepared by caſting water, or rather wine, on copper red-hot from the furnace, and catching the fumes thereof on copper plates laid over for that purpoſe; or by diſſolving copper plates in wine, much as in making verdigriſe. The painters make uſe of this colour for *graſs green*. It is ſometimes counterfeited by grinding verdigriſe with ceruſs.

GREEN, *calcined*, and *diſtilled* GREEN. See VERDIGRISE.

GREEN, *Pruſſian*. See the proceſs for making *Pruſſian* BLUE.

GREEN, *ſap*. See *Colours from* FRUITS, BUCKTHORN, and SAP-*green*.

GREEN, *Saxon*, an extremely beautiful *green* colour, the proceſs of dying which is this: the cloth or ſilk is firſt to be dyed a *Saxon* BLUE, in the following manner. Having ground nine parts of indigo with twenty of red arſenic into a fine powder, add forty-eight parts of ſtrong ſpirit of vitriol; which mixture ſwells, grows hot, and emits a ſulphureous ſmell. After ſtanding in a moderate warmth for twenty-four hours, pour off the liquid part, which will be of an extremely deep blue. A ſmall quantity of this liquor, dropt into hot water, inſtantly ſpreads, tinges it of a fine light blue, and fits it for dying the prepared wool, cloth, or ſilk; and by increaſing or diminiſhing the proportion of the blue compoſition, the colour may be rendered deeper or lighter. This, Dr. Lewis ſays, is the method uſed for preparing the blue compoſition by the dyers of Norwich, who purchaſed this ſecret from Saxony.

The cloth or ſilk, thus dyed blue, is next to be dipt in the yellow decoction of weld or ruſtic, and the deſired colour will be obtained.

Or the ſubject may be dyed *green* at one operation, by boiling it for a little time in a mixture of the blue and yellow liquors.

By thus combining any blue and yellow dyes, in different proportions, all the ſhades of *green* may be produced, from the bluiſh *green* of the cabbage-leaf to the greeniſh yellow of the olive.

GREEN *ſap*. See CAP.

GREEN *copperas*. See COPPERAS.

GREEN *earth*. See VERDITER, and TERRE *verte*.

GREEN *finch*, the Engliſh name of a ſpecies of LOXIA, being the *loxia chloris* of Linnæus, which has a ſtrong tinge of *green* diffuſed over all its body; the wings and tail are black, but both variegated with a beautiful yellow.

This bird may be eaſily tamed, by carrying it into the dark, and putting it upon one finger, and gently touching its breaſt with a finger of the other hand. By a few ſtrokes and careſſes of this kind, and letting in the light by degrees, it will eat any bruiſed ſeed out of the hand, and afterwards continue tame. See CHLORIS.

GREEN *fiſh*. See *Cod*-FISHERY.

GREEN *glaſs*. See GLASS.

GREEN-*hew*, or *green-hue*, in our *Old Writers*, the ſame with *vert* in foreſts, &c.

GREEN *hides*, are thoſe not yet tanned, or dreſſed, but ſuch as are taken off from the carcaſes. See HIDE, and CURRYING.

GREEN *muſtard*, an Engliſh name for the herb DITTANDER, or pepperwort.

GREEN *ouſel*, in *Ornithology*, the *ſaxatilis glottis* of Linnæus. See LIMOSA.

GREEN *ſickneſs*. See CHLOROSIS.

GREEN *ſilver*, the name of an ancient cuſtom within the manor of Writtle in the county of Eſſex; which is, that every tenant, whoſe fore-door opens to Greenbury, ſhall pay an half-penny yearly to the lord, by the name of *green ſilver*. Blount.

GREEN *wax* is uſed where eſtreats are delivered to the ſheriffs out of the exchequer, under the ſeal of that court, made in *green wax* to be levied in the ſeveral counties.

GREEN *weed*. See BROOM.

GREEN *winter*. See WINTER *green*.

GREENCLOTH, a board, or court of juſtice, held in the compting-houſe of the king's houſhold, for the taking cognizance of all matters of government and juſtice within the king's court royal; and for correcting all the ſervants therein, that ſhall any way offend.

To this court alſo belongs the authority of maintaining the peace for twelve miles round the king's court, wherever it ſhall be, excepting at London.

The judge of this court is the lord ſteward, aſſiſted by the treaſurer, comptroller, cofferer, clerks of the *greencloth*, &c. It takes its name, *greencloth*, from a green cloth ſpread over the board where they ſit, whereon are the arms of the compting-houſe.

GREENCLOTH, *clerks of the*, are three officers of the board of *greencloth*, who attend there, and have buſineſs aſſigned them by the board. All bills of comptrolments, relating to the office, are ſummed up, and allowed by the clerks comptrollers, and audited by the clerks of the *greencloth*.

They alſo appoint the king's, queen's, and houſhold's diet, and keep all records, ledgers, and papers, relating thereto; make up bills, parcels, and debentures for ſalaries, &c. and proviſions and neceſſaries for the officers of the pantry, buttery, cellar, &c.

GREENHOUSE, or *conſervatory*, a houſe or ſhelter in a garden; contrived for preſerving the more tender and curious exotic plants, which will not bear the winter's cold abroad in our climate.

Greenhouſes, as now built, ſerve not only as conſervatories, but likewiſe as ornaments of gardens; being uſually large and beautiful ſtructures, in form of galleries, wherein the plants are handſomely ranged in caſes for the purpoſe.

The length of *greenhouſes* muſt be proportioned to the number of plants intended to be preſerved in them, and cannot therefore be reduced to rule; but their depth ſhould never be greater than their height in the clear, which, in ſmall or middling houſes, may be ſixteen or eighteen feet, but in large ones from twenty to twenty-four feet; and the length of the windows ſhould reach from about one foot and a half above the pavement, and within

within the same distance of the ceiling, which will admit of a corniche round the building over the heads of the windows. Their breadth cannot be in proportion to their length; for if in the largeſt buildings they are more than ſeven or ſeven feet and a half broad, they will be extremely heavy and inconvenient. The piers between the windows muſt be as narrow as may be, to ſupport the building; for which reaſon they ſhould either be of ſtone, or of hard burnt bricks.

If the piers are made of ſtone, they ſhould be thirty inches wide in front, and ſloped off behind to about eighteen inches, by which means there will be no corners to take off the rays of the ſun. If they are of brick, they will require to be at leaſt three feet in front, but they ſhould be in the ſame manner ſloped off behind. Over the *greenhouſe* may be rooms for drying and preſerving ſeeds, roots, &c. and behind it a place for tools and other purpoſes; and both theſe behind, and the rooms above, will be of great uſe in keeping off the froſts, ſo that the wall between theſe need not be of more than two bricks and a half in thickneſs.

The floor of the *greenhouſe*, which ſhould be laid either with Bremen ſquares, Purbeck ſtone, or flat tiles, muſt be raiſed two feet above the ſurface of the adjoining ground, or if the ſituation be damp, at leaſt three feet; and if the whole is arched with low brick arches under the floor, they will be of great ſervice in preventing damps; and under the floor, about two feet from the front, it will be very adviſeable to make a flue of ten inches wide, and two feet deep; this ſhould be carried the whole length of the houſe, and then returned back along the hinder part, and there be carried up into funnels adjoining to the tool-houſe, by which the ſmoke may be carried off. The fire-place may be contrived at one end of the houſe, and the door at which the fuel is put in, as alſo the aſh-grate, may be contrived to open into the tool-houſe, and the fuel being laid in the ſame place, the whole will be out of ſight. Bradley recommends the new STOVE invented by M. Gauger, and publiſhed by Dr. Deſaguliers. Bradley alſo adviſes, that the front of *greenhouſes*, in the colder parts of England, be built in a ſweep or ſemicircle, ſo that one part or other of it may receive the ſun's rays all day. The uſe of fires muſt, however, be very ſparing in this place; and it is not one winter in three or four that will require them in any part, only when the weather is very ſevere, and the froſt cannot well be kept out any other way, this is an expedient that is good to have in readineſs, as it may ſave a whole houſe of plants. Within-ſide of the windows, in front of the *greenhouſe*, there ſhould be good ſtrong ſhutters, made with hinges, to fold back cloſe to the piers, that they may not obſtruct the rays of the ſun. Theſe ſhutters need not be more than an inch and a half thick. The back part of the houſe ſhould be either laid over with ſtucco, or plaiſtered with mortar, and white-waſhed, in order to prevent the froſty air from penetrating through the walls. When the *greenhouſe* is wainſcotted, the walls ſhould be plaiſtered with lime and hair behind the wainſcot, to keep out the cold; and the wainſcot, as well as the cieling, and every part within the houſe, ſhould be painted white, for the reflection of the ſun's rays. There muſt be a number of treſſels, with forms of wood upon them, to ſupport the pots of plants, the talleſt to be placed hindmoſt, the loweſt within four feet of the windows; and the rows of plants ſhould riſe gradually, ſo that the heads of the ſecond row ſhould be entirely above the firſt; and behind them there ſhould be a ſpace of at leaſt five feet, for the convenience of watering the plants, and for a free circulation of air. It has been obſerved that the placing of the euphorbiums, cereuſes, and other ſucculent plants among orange-trees, and other common *greenhouſe* plants, is always deſtructive of them, by making them receive an improper ſort of effluvia, which plants of that kind inhibe very freely. They ſhould therefore be placed in two wings built at each end of the *greenhouſe*, which, if well contrived, will be a great beauty, as well as uſe, to the building. Theſe wings may be made capable of a greater warmth alſo by more flues, and may be made to contain a hot-bed of tanners bark for the raiſing many of the tender plants, natives of warm climates.

Whilſt the front of the *greenhouſe* is exactly ſouth, one of the wings may be made to face the ſouth-eaſt, and the other the ſouth-weſt. By this diſpoſition the heat of the ſun is reflected from one part of the building to the other all day, and the front of the main *greenhouſe* is guarded from the cold winds. Theſe two wings may be ſo contrived as to maintain plants of different degrees of hardineſs, which may be eaſily effected by the ſituation and extent of the fire-place, and the manner of conducting the flues: the wing facing the ſouth-eaſt is evidently the moſt proper for the warmeſt ſtove; this may be divided in the middle by a partition of glaſs, with glaſs doors opening from one diviſion to the other. In each of theſe there ſhould be a fire-place, with flues carried up againſt the back wall, through which the ſmoke ſhould be made to paſs, as many times the length of the houſe as the height will admit of the number of flues; for the longer the ſmoke is in paſſing, the more heat will be given to the houſe, with a leſs quantity of fuel. The other wing, facing the ſouth weſt, ſhould be diviſded and furniſhed with flues in the ſame manner; and thus different degrees of heat may be obtained, according to the ſeaſons, and the particular ſorts of plants that are to be preſerved. If there are no ſheds behind theſe wings, the walls ſhould not be leſs than three bricks thick, and the back part, having ſloping roofs, which are covered with lilet or ſlates, ſhould be lined with reeds, &c. under the covering. The ſloping glaſſes of theſe houſes ſhould be made to ſlide and take off, ſo that they may be drawn down more or leſs, in warm weather, to admit air to the plants; and the upright glaſſes in front may be ſo contrived, as that every other may open as doors upon hinges, and the alternate glaſſes may be diviſded into two, the upper part of each ſhould be ſo contrived as to be drawn down like ſaſhes, ſo that either of them may be uſed to admit air, in a greater or leſs quantity, as there may be occaſion. Miller.

As to the management of the plants herein, Mortimer recommends the opening of the mould about them, from time to time, and ſprinkling a little freſh mould in them, and a little warm dung on that; as alſo, to water them when the leaves begin to wither and curl, and not oftener; which would make them fade, and be ſickly; and to take off ſuch leaves as wither, and grow dry.

It is a general rule among gardeners, to ſet exotic plants in the *greenhouſe* about the ſecond week in September, and to take them out again about the middle of May; though there ſhould be ſome diſtinction made herein; the tendereſt ſorts from places near the line, as the aloes, &c. being to be confined longer to the *greenhouſe* than oranges, myrtles, &c.

GREENLAND *fiſhery*. See *Whale* FISHERY.

GREENLAND *company*. A joint ſtock of 40,000*l.* was by ſtatute to be raiſed by ſubſcribers, who were incorporated for fourteen years from the firſt of October, 1693, and the company to uſe the trade of catching whales, &c. into and from *Greenland*, and the *Greenland* ſeas; they may make bye-laws for government, and of the perſons employed in their ſhips, &c. Stat. 4 and 5 W. III. cap. 17. This company was farther encouraged by parliament in 1696; but partly by unſkilful management, and partly by real loſſes, it was under a neceſſity of entirely breaking up, before the expiration of the term aſſigned to it, ending in 1707. But any perſon who will adventure to *Greenland* for whale fiſhing, ſhall have all privileges granted to the *Greenland* company, by 1 Anne, cap. 16. and thus the trade was again laid open. Any ſubjects may import whale-fins, oil, &c. of fiſh caught in the *Greenland* ſeas, without paying any cuſtoms, &c. ſtat. 10 Geo. I. cap. 16. And ſhips employed in the *Greenland* fiſhery are to be of ſuch burden, provided with boats, ſo many men, fiſhing lines, harping irons, &c. and be licenſed to proceed; and on their return ſhall be paid 20*s.* per ton bounty, for whale-fins, &c. imported. 6 Geo. II. cap. 33. See *Whale*-FISHERY.

GREENWICH *hoſpital*. See HOSPITAL.

GREGARIOUS *birds*, are ſuch as do not live ſolitarily, but aſſociate in flights or coveys, a great many together in company.

GREGORIAN *calendar*. See CALENDAR.

GREGORIAN *chant*. See CHANT.

GREGORIAN *code*. See CODE.

GREGORIAN *epocha*, is the epocha, or time, whence the *Gregorian* calendar, or computation, took place.

The year 1780 is the 298th year of the *Gregorian* epocha.

GREGORIAN *year*. See YEAR.

GRENADA. See GRANADO.

GRENADIER. See GRANADIER.

GRENAILLE, a name given by the French writers to a preparation of copper, which the Chineſe uſe as a red colour in ſome of their fineſt china, particularly for that colour which is called *oil-red*, or *red in oil*. The china-ware coloured with this is very dear. The manner in which they procure the preparation is thus: they have in China no ſuch thing as ſilver-coined money, but they uſe in commerce bars, or maſſes of ſilver; theſe they pay and receive in large bargains; and among a nation ſo full of fraud as the Chineſe, it is no wonder that theſe are often adulterated with too great an alloy of copper. They paſs, however, in this ſtate in the common payments. There are ſome occaſions, however, ſuch as the paying the taxes and contributions, on which they muſt have their ſilver pure and fine: on this occaſion they have recourſe to

certain

certain people, whose sole business it is to refine the silver, and separate it from the copper and the lead it contains. This they do in furnaces made for the purpose, and with very convenient vessels. While the copper is in fusion, they take a small brush, and dip the end of it into water; then striking the handle of the brush, they sprinkle the water by degrees upon the melted copper; a sort of pellicle forms itself by this means on the surface of the matter, which they take off while hot with pincers of iron, and immediately throwing it into a large vessel of cold water, it forms that red powder, which is called the *grenaille*; they repeat the operation every time they in this manner separate the copper; and this furnishes them with as much of the *grenaille* as they have occasion for in their china works. Observations sur les Coûtumes de l'Asie, p. 309.

GRESHAM *college*. See COLLEGE.

GRESLING, in *Ichthyology*, a name given by the Germans to the *gobius fluviatilis*, or *common* GUDGEON, which is very frequent in their smaller rivers.

GRESSURA, a word used by some writers, to express the part between the pudenda and the anus. See PERINÆUM.

GREVE, GREFFA, among our *Ancient Writers*, is a denomination of power and authority; signifying as much as *comes* or *vicecomes*. See COUNT and VISCOUNT.

The word is formed from the Anglo-Saxon *grith*, *peace*. Thus Horeden: Greve *dicitur, ider quod jure debeat* grith, i. e. *parem ex illis facere, qui patriæ inferunt væ*, i. e. *mo feriam vel mulctam*.

Lambard makes *greve* the same with *reve*.

Hence, also, the words *shrieve*, *portgreve*, &c. which were anciently written *sciregrefa*, *portgrefa*, &c.

GREWIA, in *Botany*, a genus of the *cynandria polyandria* class. Its characters are these: the flower hath a five-leaved empalement; five petals, which are indented at their base, where is situated a fealy nectarium to each; and hath many briftly ſtamina; in the centre is ſituated a roundiſh germen, which is lengthened in form of a column, and becomes a four-corned berry with four cells, each incloſing one globular ſeed. Miller reckons two ſpecies, natives of Africa, and Linnæus four.

GREWT, in *Mineralogy*, a word uſed by our miners to expreſs earth, but particularly that earth found in the flat countries, and in the banks of rivers, in their ſearches after mineral veins, which is different in colour and nature from the reſt of the bank or bottom. This they always underſtand to have been waſhed off from the neighbouring hills, in the time when the ſhoad-ſtones, by which they train their new mines, were alſo waſhed down, that is at the univerſal deluge: and this wherever found, proves of great uſe to them in theſe reſearches, as it ſhews which way the waſh from the hill has run, and directs them how to trace the reſt, and where to look for the ſhoad-ſtones with any probability of ſucceſs. They generally examine the banks of rivers, where they have been worn away by land floods, in order to find theſe *grewts*, and then examine, in a ſtraight line with the next hill, though four or five miles off; and if there be any mine there, they generally meet with ſhoad-ſtones, as tokens of it in the way. Phil. Tranſ. N° 69.

GREY. See GRAY.

GREY, in *Ichthyology*, an Engliſh name for a trutiaceous fiſh, the SALMO *eriox* of Linnæus, caught in many of the rivers of England. It is a very large fiſh, often growing to the full ſize of the larger ſalmon, but differing from that ſpecies, in the body being broader, and the head large in proportion; in the jaws are four rows of teeth, and on the tongue are eight teeth; the back and ſides, above the lateral line, are of a deep *grey* colour, ſpotted with a number of purpliſh ſpots, whence its name; the belly is ſilvery; its tail is not forked, and its fleſh is much finer taſted than the ſalmon; and in the places where both are to be had, the *grey* ſells at the larger price. It comes up into the freſh-waters in the month of Auguſt, and is a very ſcarce fiſh.

Mr. Pennant believes this to be the *ſewin* or *ſhewin* of South Wales, which is very common in the neighbourhood of Carmarthen. This fiſh appears in the Eſk, in Cumberland, from July to September, and is then in ſpawn. The lower jaw grows hooked, when it is out of ſeaſon. The inhabitants of the North of England and of South Wales conſider this fiſh as a diſtinct ſpecies from the Salmon.

GREY *fly*. See GAD-*fly*.

GREYHOUND. See HOUND and DOG.

GREYHOUNDS, in *Aſtronomy*. See CANES *venatici*.

GREYLAG *goose*. See GOOSE.

GRIAS, in *Botany*, a genus of the *polyandria monogynia* claſs; the characters of which are, that the flower hath four petals; the calyx is divided into four ſegments; and the fruit is a drupe, containing an eight-furrowed nucleus.

GRICE, a term uſed by country perſons for a young wild boar.

GRIEF. The influence of this paſſion on the body is very great, ſo as often to deſtroy all appetite and deſire of meat, either by inſpiring men with a diſreliſh for life, or by a mechanical inſtinct; becauſe food taken at ſuch a time makes but bad nouriſhment, fitter to corrupt the blood than prolong life; on which account it is aſſigned as a phyſical cauſe for the FASTING practiſed among the heathens. The influence of this paſſion extends itſelf even to beaſts; which, when indiſpoſed, not only take no pains to provide themſelves food, but alſo refuſe it when laid before them. Vide Mem. Acad. Inſcript. tom. v. p. 50, ſeq. This paſſion has been found to leſſen PERSPIRATION and urine.

GRIELUM, in *Botany*, a genus of the *decandria pentagynia* claſs; the characters of which are, that the calyx is divided into five ſegments; the flower has five petals; and the fruit conſiſts of five monoſpermous pericarpia.

GRIFFON, GRYPHUS, γρυψ, in *Natural Hiſtory*, the name of an imaginary bird of prey, of the eagle kind.

The ancients ſpeak fabuloſuſly of the *griffon*: they repreſent it with four legs, wings, and a beak; the upper part repreſenting an eagle, and the lower a lion: they ſuppoſe it to watch over gold-mines, hidden treaſures, &c.

The animal was conſecrated to the ſun; and the ancient painters repreſented the chariot of the ſun as drawn by *griffons*. M. Spanheim obſerves the ſame of thoſe of Jupiter and Nemeſis.

The *griffin*, in Scripture, is that ſpecies of the eagle called in Latin, *oſſifraga*, the *oſprey*; and גְּרִיפוֹן, of the verb גָּרַף, *parat, to break*.

The *griffon* is frequently ſeen on ancient medals; and is ſtill borne in coat-armour.

Guillim blazons it *rampant*, alledging, that any very fierce animal may be ſo blazoned, as well as the lion. Sylveſter, Morgan, and others, uſe the term *ſegreant*, inſtead of rampant.

This is alſo an ornament of architecture in conſtant uſe among the Greeks, and was copied from them, with the other elegancies of architectural enrichments, by the Romans. See SPHYNX.

GRIG, in *Ichthyology*, a name frequently uſed for the ſand eel, or AMMODYTES.

Theſe are common in the Thames, and are diſtinguiſhed from the common ſort by having a larger head, a blunter noſe, thicker ſkin, and leſs fat; and they are not ſo much eſteemed, and ſeldom exceed three or four ounces in weight.

GRILLADE, in *Cookery*, meat broiled on the gridiron; thus called from the French *griller*, *to broil*.

The word is alſo uſed for the browning of any diſh, by rubbing a red-hot iron over it. To *grill* oyſters, is to put them into ſcollop-ſhells, ſeaſon them with ſalt, pepper, and parſley ſhred, and pour their own liquor to them, covering them with grated bread, ſtewing them half an hour on the fire, and browning them with a red-hot iron. Shrimps are *grilled* after the ſame manner.

GRIND-*ſtone*, *cos granitis*, in *Natural Hiſtory*, is a very *coarſe*, *rugged*, rough, and harſh ſtone, of a yellowiſh brown colour, compoſed of an irregular grit, cemented together by a coarſe and debaſed terrene cryſtalline matter, and intermixed with a very few glittering ſpangles of white talc: it cuts freely, but bears no polith; it is pervaded by water, will not ſtrike fire with ſteel, is not acted upon by acids, and burns to a deep red colour, but acquires no hardneſs. It is chiefly dug in the northern counties of England, and uſed for *grind-ſtones*, whence its name.

GRINDING, *trituration*, the act of breaking or comminuting a ſolid body, and reducing it into powder, duſt, flour, farina, or the like.

Grinding is one of the ſpecies of diſſolution. The painters colours are ground on a marble or porphyry, either with oil or gum-water.

Some late phyſicians contend, that DIGESTION is performed by *grinding* the food in the ſtomach. It is alledged, that every part in the body is a veſſel or veſſels; and all the veſſels have a motion of ſyſtole and diaſtole; all the operations of the body conſiſt in the attrition or *grinding* of the humours or matters contained in ſuch veſſels.

GRINDING is alſo uſed for rubbing or wearing off the irregular or otherwiſe redundant parts of the ſurface of a body, and reducing it to the deſigned figure, whether that be flat, concave, or the like.

The *grinding of gloſſes* is a conſiderable art, and, as ſuch, neceſſarily requires to be here inſiſted on; eſpecially that of optic glaſſes.

Method of GRINDING *optic-gloſſes*. For convex glaſſes, the firſt object is to provide a diſh or baſon, within whoſe cavity the glaſs is to be formed.

In

In order to this, they take a piece of braſs, copper, iron, or wood, and form it into a ſegment of a circle, having the radius of the baſon or the diſh intended: this done, a baſon is forged by a ſmith, either of iron or copper, having its cavity exactly fitting or correſponding to the ſegment above mentioned, though ſometimes they chuſe to have the baſon caſt; in this caſe, the rules elſewhere delivered for concave MIRRORS are to be here obſerved. The figure of the baſon, thus roughly formed, is to be finiſhed in the pewterers lathe, or on a ſtone mould *A*, *Tab.* II. *Optics*, *fig.* 22. fixed to an iron axis with a pinion BC, moveable by a wheel D E, and that by a winch or handle F. The baſon being ground on the mould till it exactly fit in all parts, they take it off, and cementing it to a wooden block (loaden, if need be, with lead), ſtrew it over with fine-ſifted ſand, and thus grind it over again on the mould, till all the ſcrows or ſcratches be quite taken away.

Laſtly, they grind large pieces of glaſs in a baſon, with fine ſand between, till ſuch time as its ſurface being well ſmoothed, there is no longer any oppoſition to the motion.

Note, the diſh is known to be perfectly finiſhed when, a hair being ſtretched over it, its ſhadow projected in the cavity, eſpecially in a camera obſcura, does not appear any way diſtorted.

The baſon finiſhed, they proceed to chuſe glaſſes for the purpoſe: in order to this, lay them on clean paper, and obſerve what colours are projected thereon; for the ſame are the colours of the glaſſes. Always ſet aſide thoſe of the darker colours, and chuſe the brighter; but as thoſe whiteſt and brighteſt have uſually veins, and beſides, in tract of time, by the humidity of the air, are apt to ruſt and loſe their poliſh; for this reaſon Huygens recommends thoſe a little yellowiſh, reddiſh, or greeniſh; Hevelius the blueiſh. A glaſs is found to be free from bubbles, ſands, veins, knots, and ſpires, by holding it to the ſun, and receiving the rays through it on a white paper; for the flaws above mentioned will each project a ſhadow thereon.

If, inſtead of lenticular, or at leaſt ſpherical glaſſes, you make uſe of plate-glaſs, it muſt be divided and cut with a diamond into ſquares; and if it be too thick to break otherwiſe, you may do it by laying it on a table covered with cloth, in ſuch manner as that the ſide or part to be ſevered hang over the edge: for, being ſtruck with an iron inſtrument, in this ſituation, it eaſily breaks in the direction of the line drawn by the diamond. Having thus got a ſquare piece, deſcribe two concentric circles thereon with a pair of compaſſes, one of whoſe legs carries a diamond; the diameter of the inner circle to be equal to the breadth of the intended lene, and that of the outer ſomewhat more; and break off the corners, as above directed, and the leſſer inequalities take off on a grind-ſtone, or the like. Examine now whether the piece of glaſs be every-where equally thick; if it be not, reduce it to ſuch equality by *grinding* it on an iron plate with ſand and water. Laſtly, glue or cement the glaſs thus prepared to a wooden handle NMO, *fig.* 23. with a cement made of pitch and a fourth part of reſin, or one part of wax and eleven of colophony: care to be taken that the baſe or bottom of the handle NO be equal to the glaſs, and that the centre of the glaſs and handle meet together. Smaller lenſes, as thoſe uſed for microſcopes, are fixed on with ſealing-wax.

Now, to grind the glaſs, and bring it to the convexity required, ſmear over the diſh equally with fine ſifted ſand moiſtened with water; then taking the handle with the glaſs thereon, work it on the baſon, ſometimes this way, and ſometimes that, to prevent the form of the baſon from being diſturbed, never leaning too hard thereon. When the glaſs has got the figure of the baſon, clean it well of all the ſand and filth adhering, and ſprinkle the baſon over with emery moiſtened in water, *grinding* the glaſs thereon till all the roughneſs and inequalities are taken away: after this, the fine ſand uſed in our-glaſſes may be of ſervice, applied and uſed as before; remembering to take out the ſand, when too much worn, and ſubſtitute new in its ſtead. Some in lieu hereof, chuſe ſeveral ſorts of emery, each finer than the other, or even the powder of flint calcined and pounded. Laſtly, grind the ſame glaſs in another baſon or diſh, which is a ſegment of a leſſer ſphere, making uſe of the like ſand as before, till it has got a pretty high rim or margin all around. Becauſe the preſſion is not here determined accurately enough upon the middle of the glaſs, by the mere guidance of the hand, ſome have choſe to make uſe of the following machine, eſpecially for *grinding* object-glaſſes.

Fix the diſh H I, *fig.* 24. on a horizontal table; exactly over its centre let the aperture D be, through which paſs an iron arm five or ſix inches long, faſtened to the ſtaff AB: let the other extreme of the ſtaff be fitted into a hole cut in the diſh, and faſtened therein. Now to grind the glaſs inſtead of the diſh, take hold of the ſaid ſtaff, and work with ſand, &c. as before.

Huygens tells us, that he always uſed firſt a coarſe emery, then a finer powder of the ſame, which would be fifty ſeconds in ſinking to the bottom of a veſſel of water, putting in freſh every half or quarter of an hour: ſometimes, too, he uſed emery of fifty ſeconds, for three quarters of an hour; then emery of four hundred ſeconds, for four fifths of an hour; and laſtly, emery of forty-five minutes, for a quarter of an hour. The ſame effect is had from powder of flints, broken in an iron mortar, mixed with water, and ſtirred ſometimes with a wooden ſpatula, taking the powder as it precipitates in ſome certain time to the bottom of the veſſel, by decanting the water. What remains is to poliſh the glaſs.

For a more particular account of the method in *grinding* and poliſhing glaſſes for teleſcopes, extracted from Mr. Huygens and other authors, by Mr. Molyneux, and comprehending the method of making and poliſhing the tools, of chuſing the glaſs, of preparing the glaſſes before they can be ground and poliſhed, of *grinding* the glaſſes, and of giving them the laſt and fineſt poliſh, we muſt refer to Smith's Optics, book iii. chap. i. paſſim.

The late ingenious Mr. James Short, in a paper left with the Royal Society, to be opened and printed after his death, gives the following directions for working object-glaſſes of refracting teleſcopes truly ſpherical.

Prepare two plates or tools of braſs, the one convex, and the other concave, being both portions of a ſphere of the ſame radius as the focal length of the object glaſs you want to have, or rather of a radius ſomewhat longer than the focal length you want, for a diopirical reaſon; let theſe plates or tools be between two and three times the breadth of the object-glaſs deſired; or, in long focal lengths, twice the breadth will be ſufficient: let theſe tools be of a ſufficient thickneſs in proportion to their breadth or diameter, and let them be ground with fine emery exactly true to one another, working them alternately, the one above the other, to preſerve the ſame focal length; or, if it is deſired longer, you muſt work the convex above the concave; or, if deſired ſhorter, you muſt grind the concave above the convex.

After this, you prepare another braſs plate or tool, of the ſame breadth and thickneſs as the two former, and of the ſame radius of concavity: its being truly turned on a lathe will be ſufficient for this purpoſe; which tool is to ſerve afterwards for the poliſhing of the two ſurfaces of your object-glaſs, and therefore called the poliſhing tool.

Prepare a piece of ſtraw-coloured glaſs, of the plate-glaſs kind, of the proper diameter for the object-glaſs you deſire, which ought always to be broader than the proper aperture for that length; let this piece of glaſs be ground flat, in another tool, on both ſides, and as nearly parallel as may be, and ſomewhat poliſhed, in order to diſcover whether there are any veins or flaws in the glaſs. When you are ſatisfied of the goodneſs of the glaſs, you are then to prepare a handle to faſten your glaſs to. Great care muſt be taken in this, for fear of bending your glaſs by the handle; Mr. Short adviſes to take a flat piece of braſs, or rather of the concavity of the ſphere, to which the glaſs is to be ground; this piece of braſs ſhould not be thicker than two thirds of the thickneſs of the glaſs, of a circular form, leſs in breadth ſomewhat than the glaſs itſelf, and having ſides of the ſame form, at right angles to the flat piece of braſs, and theſe ſides ought to be of ſuch a ſhape as that the fingers may eaſily apply to it in working, and theſe ſides ſhould be as low as may conveniently be, and no thicker than about two thirds of the glaſs. This handle is to be faſtened to the glaſs, by warming the glaſs and handle gently before a fire, and laying ſome pitch upon the glaſs thus warmed, till it becomes ſoft like melted wax; and then laying your braſs handle, a little heated, on the pitch, you preſs it a little, till you are ſure there is nothing between the glaſs and the handle but pitch; you then lay down the glaſs and handle upon ſomething flat, taking care that the handle is in the middle of the glaſs, till it is entirely cold. It is very material to know, that the pitch, to be uſed for faſtening the handle to the glaſs, muſt be ſoft pitch, that has never been uſed nor melted; for any other pitch will infallibly bend the glaſs.

You then grind your glaſs in the concave tool with emery, and give it the proper figure and ſmoothing for the laſt poliſh, in the common manner.

In order to give your glaſs the laſt poliſh, which is the moſt difficult part of the whole work, you are to prepare ſome pitch for covering the before mentioned poliſhing concave tool, which is done in this manner: take ſome pitch, and melt it in an iron ladle, and let it boil
